Original Lecture.

THE INFLAMMATIONS AND THE CONGESTIONS OF THE NON-GRAVID UTERUS.

PRELIMINARY LECTURE,

BY E. R. PEASLEE, M.D., LL.D.,

PROFESSOR OF GYNÆCOLOGY IN BELLEVUE HOSPITAL MEDICAL COLLEGE.

PART I.

GENTLEMEN:—The uterine affections I am next to consider are very little understood by the general practitioner; and are the least of all settled, so far as their actual pathology is concerned, by gynæcologists themselves. It may be too much for me to expect to educe order out of the common confusion, or to reconcile the diverse opinions which exist respecting them; but I hold it to be the duty of all who have had the opportunity, and have taken the time to form definite and decided conclusions, to contribute what they may in this direction. I shall therefore offer no apology for giving my own individual and independent views, as they have been forced upon me and confirmed by the study and treatment of uterine affections for the past thirty years.

It will be understood that my subject includes all the inflammations and the congestions to which the uterus is liable, except during gestation, and during the usual period of convalescence after parturition; and the three principal causes of the hitherto unsatisfactory progress respecting them will need to be considered at the outset.

1. Vague and incorrect ideas of the nature and peculiarities of inflammation.

2. The assigning to inflammation a too extensive influence in uterine pathology.

3. The mistaking another entirely different condition for inflammation.

I. Though the consideration of inflammation in a general way belongs to general pathology, I find it necessary, for the reason just assigned, to premise the views I have for so long a time held, and publicly taught since 1845; and without the aid of which, as I believe, the subjects I am next to speak of cannot be rightly understood. I need not explain how my attention was first turned to this subject, nor allude to my inquiries in this direction, further than to say that I commenced by endeavoring to understand, and by experimentally testing everything which had been previously done* by others—proving my own views by the microscope and by clinical observation. I am not, I may also add, unaware of the views since promulgated by the Edinburgh School of Medicine, and by German pathologists, especially Virchow, and others,* while finding my own scarcely at all modified, except as new discoveries have tended to confirm them.

I shall confine myself to inflammation in the vascular tissues, in order to avoid a discussion here, which would otherwise arise—merely remarking that the "parenchymatous inflammation" of Virchow, and which may occur in cartilage, is, for me, not inflammation at all.

It would also be foreign to my present purpose to discuss the subject of inflammation and congestion in a systematic manner. I can here only summarize my views in an aphoristic form, under the following nine propositions:

1. Inflammation is not a mere *state* of a part, as quoted from Celsus for almost 1,700 years, in which there is redness, heat, pain, and swelling. It is a *process* going on in the part, and the four signs just mentioned do not distinguish it from still another pathological condition.

2. Congestion, on the other hand, is merely a state of a part, in which redness, heat, pain, and swelling may exist; but it is *not* a process.

3. Inflammation has its own characteristics, immediate effects, and sequelæ, if any at all ensue, and they very frequently do ensue. Congestion also has its own effects and sequelæ, both differing, however, from those of inflammation, and much more rarely ensuing.

4. Inflammation is *not the reparative process*, as is still asserted on the now obsolete authority of Hunter, who would scorn such a proposition were he the physiologist of to-day instead of a century ago. But it is directly opposed to and preventive of it. If inflammation attack a wound while healing, the reparative process is at once arrested, and a retrograde action ensues till the inflammatory process ceases.

5. Inflammation is a process, *sui generis*, as shown by its phenomena and effects; the reparative is another process, unlike all others in its symptoms and results. The former is always pathological, always to be deprecated, and never to be invoked; the latter is always a physiological process, and always desirable in the circumstances in which it can occur.

An exception to the first part of the preceding sentence is found in the use of blisters. Certain apparent exceptions I cannot stop to specify.

6. Inflammation is always the same process† wherever found, though modified by the structure and the state of the part. It very rarely occurs primarily in the muscular tissue, whether striated or non-striated. Congestion is also rare in the former, but very common in the latter; and in the uterus and the ovaries it is, during menstruation, a physiological condition.

7. Inflammation is frequently accompanied or followed by suppuration and by ulceration; but both these may occur independently of it. The presence of either in a part, therefore, is not to be accepted as proof of the previous existence of inflammation there.

* By Wilson Phillips, John Thompson, Gendrin, Kaltenbrunner, Gerber, Müller, Alison, Lobert Gulliver, Lister, Sen., Addison, C. J. B. Williams, and Hughes Bennett.

* Wharton Jones, Henle, Virchow, Paget, John Simon, Joseph Lister, Stricker, Cohnheim, Recklinghausen, Prussak, and Beale.

† The only modifications of inflammation of practical importance are the sthenic and the asthenic forms.

without other corroborative facts. Suppurative and ulcerative inflammation are terms really indicating no peculiarity in the process itself, but only in the disposal of the inflammatory exudation.

8. Inflammation is essentially an acute process, *i.e.*, it is perfectly developed and brought to an end in a few days at longest, and often in a few hours, from the attack. This process may, however, be repeated an indefinite number of times in a part, with intervals of varying duration, though always itself characterized by a short duration.

Congestion, on the other hand, may continue through protracted periods—many months, and even many years.

9. Chronic inflammation is, therefore, a contradiction and a chimera. And I find that all the chronic inflammations, so called, of the uterus, are simply chronic congestions of that organ. Actual inflammation may, however, recur from time to time, in a chronically congested part—there to rapidly run its course and disappear.

The *characteristics* of the inflammatory process, which distinguish it from all other processes, will appear as I speak next of its local and its general phenomena.

CHARACTERISTICS OF INFLAMMATION.

Whatever view in other respects may be held of inflammation occurring in vascular parts, it must be admitted that its most prominent characteristic is an exudation of the plasma of the blood into the extravascular spaces, and among the histological elements of the part affected. For, if it be asserted with Alison, who wrote nearly forty years ago, and more recently with Virchow, that a *tendency* only to exudation characterizes inflammation, that tendency is never discoverable till the exudation has actually occurred. But since this term is sometimes used instead of effusion, and *vice versa*, and sometimes even instead of extravasation, the precise meaning of each of these words should be here defined.

1. By effusion is meant the escape from the blood-vessels of the serum (nearly) of the blood, the fibrin, and the blood-corpuscles still remaining in them. An effusion cannot become organized, since it contains no fibrin; but may remain indefinitely, to produce œdema or swelling of the part, or may be absorbed. Effusion very often occurs as a consequence of passive congestion, but not of inflammation.

2. By exudation is understood the escape of the plasma of the blood, or *liquor sanguinis*—*i.e.*, all the blood except the corpuscles, from the blood-vessels,* among the histological elements of the part. An inflammatory *exudation* is therefore *organizable*. Chloride of sodium, phosphates, and albumen exist in it in larger proportion than in the blood (Simon).

3. By *extravasation* it is understood that the blood, all its constituents included, escapes from the vessels among the structural elements of the part.† This may occur in connection with either congestion or inflammation, but accidentally, and not as a characteristic of either. An extravasation is not organizable, since the presence of the blood-corpuscles, constituting very nearly one-half of the bulk of the blood, interferes with the organization of the associated plasma. It may remain for an indefinite period, still fluid or coagulated, or be absorbed, or be converted into a purulent mass and be discharged. In certain low conditions an exudation may become red, not from the presence of the corpuscles, but merely of the coloring matter of the blood (Paget). Effusion, exudation, and extravasation—all alike produce œdema or swelling of the part, which is therefore not a sign of inflammation only. The local characteristic of inflammation is the exudation.

But another recognized local sign of inflammation is increased redness of the part. This, of course, is not to be detected in parts not visible; but, admitting its existence, it also equally exists in congestion, and is therefore not distinctive as a characteristic.*

And the same may be said of the existence of increased heat as a sign of inflammation in the part; it can be verified only in parts which can be directly or indirectly reached; and it also occurs in active congestion, though in a minor degree.

In regard to pain and tenderness on pressure, of which so much has been written, as a sign of inflammation, it should be remarked that it is not very seldom absent in inflammation, while it is also very often, and in some parts almost universally present in congestion. Pure neuralgia also occurs, of course independently of either of these conditions. Pain is therefore not a characteristic of inflammation, though a valuable symptom as directing attention to the affected organ, whether inflamed or otherwise.

But the capillaries of an inflamed part are in a peculiar and characteristic condition, as is also the blood in those capillaries. The former are dilated to the utmost degree short of rupture (and sometimes the latter when extravasation occurs, as has been seen), and the blood within them is stagnant, and consists of corpuscles alone—the *liquor* having exuded into the inter-capillary spaces. The corpuscles are also very adherent to the capillary walls.

The characteristic local signs of inflammation are therefore:

1. A peculiar state of the capillaries of the part.
2. A peculiar state of the blood in those capillaries.
3. An exudation into the inter-capillary spaces.

Redness, heat, pain, and swelling may also exist; but if so, they are not distinctive of this process.

Since the normal process of nutrition implies first a normal circulation, or supply of blood to the part; secondly, an exudation of plasma in the quantity required; and thirdly, its assimilation, or conversion into the tissue to be nourished—the inflammatory process is, in its nature, a perversion of the nutritive; both the circulation (or blood supply) and the exudation being abnormal, and the latter always excessive. The reparative process, on the other hand, is simply an exaggeration of the nutritive; the circulation and the exudation being increased just sufficiently to meet the demands for the repair.

Inflammation is also characterized by two general phenomena—an increase of fibrin in the blood as a whole, and a febrile reaction of a peculiar form.

Fibrin,† normally constituting 3 parts in 1000 of blood, has, in all inflammations decided enough to demand therapeutical interference, been found to be doubled at least, and is sometimes tripled. In

* Exudation is a mode of exosmosis through the capillary walls, they being a soft protoplasm, like a film of collodion (Virchow), homogeneous and sometimes nucleated.

† Extravasation usually implies a rupture of the capillaries: but Cohnheim (1868) and Recklinghausen have discovered the red corpuscles as well as the white, passing through their walls, and leaving no perceptible opening behind. Sometimes the red corpuscles are seen to be held for a time by the capillary walls, producing a constriction—one-half being within and the other outside of the vessel.

* The redness of inflammation is at first crimson, and darker than of active congestion: and often becomes livid. It is not removed by pressure; the redness of active congestion is so. It continues in the part after death; that of active congestion disappears. The redness of chronic *passive* congestion is with difficulty and but partially removed by pressure, and very slowly returns. When extreme and livid, it partially remains after death.

† The concrete fibrin (Denis), and not the dissolved fibrin or metalbumen, is here meant.

some diseases, as pneumonia and acute rheumatism, it rises to 9 and even 10 parts in 1000. This increased production of fibrin (hyperinosis) ceases with the cessation of the inflammation; but it cannot be made available in diagnosis, unless a considerable amount of blood is taken for examination.

But the febrile reaction, which is never absent in cases of inflammation severe enough to require treatment, is a most reliable sign.

It is very important, however, to distinguish this form of pyrexia from the fevers proper; and I refer you to the first volume of Miller's Principles and Practice of Surgery* for an able account of inflammatory fever, as it is there called. If it occur in a part, together with the four symptoms quoted from Celsus, it may be relied upon as deciding for inflammation as against mere congestion. And, conversely, the presence of heat, redness, pain and swelling, without the inflammatory pyrexia, indicates congestion merely. The fever will be either sthenic or asthenic (adynamic, typhoid) according to the form of the inflammation. In many instances it is the high temperature, and not the pain of inflammation, which exhausts and finally destroys the patient.

I conclude, then, that:

Inflammation is a process, sui generis, though a perversion of the nutritive process—characterized by an abnormal state of the vessels (the capillaries especially) of the part—and of the blood in those vessels, and by an excessive exudation of the blood-plasma into the intervascular spaces.

It is also characterized by a notable excess of fibrin in the blood as a whole, and by a febrile reaction of a peculiar kind.

I cannot here speak of the causes of inflammation, nor explain how they act, whether upon the vaso-motor nerves, or the muscular fibres of the minute vessels, and thus directly or indirectly. But it is necessary here to understand the various ways in which the inflammatory exudation, causing the swelling, as has been seen, may be subsequently disposed of. It must, however, be premised that the inflammatory process is exhausted, and brought to an end by the exudation; and all the changes subsequently occurring in the part constitute the "sequelæ" or "consequents" of inflammation.

A. In case the inflammatory process has occurred on a free surface—serous membrane, mucous membrane, or the skin—the exudation may be disposed of in the following ways:

1. An exudation upon a serous membrane, as in pleurisy or peritonitis, producing first a detachment of the epithelial layer to a greater or less extent, may

a. Be promptly absorbed (and in resolution).

b. Or remain for a considerable time in a fluid state in the serous cavity, and finally become purulent.

c. Or become coagulated, thus forming flakes of fibrin, or a so-called false membrane, which, becoming organized, constitutes adhesions of various forms.†

2. If the exudation occur upon a mucous membrane, it raises the epithelium from the basement layer (*i.e.*, produces an abrasion), if there be but a single layer of cells, and sometimes even if there be several, as when it occurs around the os uteri, producing the misnamed "ulceration" there. Thus the exudation arrives upon a free surface, where it undergoes the highest organization possible in the circumstances (exposed to the air and to motion); *i.e.*, it is developed into pus-cells, which, mingling with the epithelial cells, form a dense fluid, at first slight in quantity, and tinged by commixture with blood-corpuscles, but afterwards of a yellowish, creamy appearance, from the rapid formation of the epithelial elements. It has long been observed that there is very little, if any, pain in case of inflammation upon a mucous membrane after pus appears there; for the now very apparent reason that the inflammation has previously subsided. The abrasion also shows inflammation to have previously existed in these cases, and to have ceased.*

In some localities, however (the air-passages, vagina, etc.), the exudation may, instead of developing pus-cells, undergo coagulation, as upon a serous membrane, and thus a so-called false membrane be formed. An illustration is found in croup, and sometimes in vaginitis. This is by the German pathologists called "croupous inflammation;" but the process is the same as in other instances—the exudation simply being coagulated, as if upon a serous membrane.

On both serous and mucous membranes the secretion is greatly diminished (or arrested), and the quality changed.

3. In inflammation of the skin, also, the exudation raises and detaches the epithelium (produces a blister), and then undergoes the same change as usually on a mucous membrane; or if more deeply seated, it causes swelling of the derma or cutis vera, as in the parenchyma of an organ, and may then be absorbed, or converted into pus and be discharged. Both the vesication and the swelling may usually be seen (and sometimes also the suppuration) at the same time in different parts of a surface attacked by erysipelas. Virchow terms inflammation on the free surface "exudative," in reference to the throwing off of the exudation, as I have explained; an expression which, since the inflammatory process itself here presents no peculiarity, is calculated to mislead.

B. If inflammation attack the parenchyma or substance of an organ,† *i.e.*, is not on a surface, the exudation, causing a soft swelling of the part, may—

a. Be promptly absorbed, and the swelling removed; *i.e.*, resolution occurs.

b. Or it may remain fluid and become purulent, and then be discharged.

c. Or it may become coagulated and subsequently organized, and thus finally cause solidification or so-called *induration* of the part.

It has often been asserted that softening is the result of acute, and induration of chronic, inflammation. In fact, the former is merely the immediate effect of the presence of the inflammatory exudation in a part, while the latter is simply the result of its subsequent organization.

But induration must here be distinguished from another condition often mistaken for it,—I mean hypertrophy. The former results from the formation of new tissue among the original histological elements of the part, and which increases its size and solidity, as water absorbed by a sponge first increases the size and softness of the mass; but if the water subsequently be frozen, the whole is converted into a solid mass. Hypertrophy, on the other hand, is an actual growth

* Page 49 52.

† To call inflammation on a serous surface "adhesive," is therefore a misnomer. The adhesion results simply from the organization of the exudation on a membrane deprived of epithelium, in a state of almost entire rest, and secluded from the air.

* Of course, abrasions may occur independently of inflammation, as from ingesta directly denuding the epithelium.

† The parenchymatous inflammation of Virchow is not to be understood, but a process also occurring in muscular tissue, as cartilage; differing entirely from the proper inflammation in vascular parts, which I am considering, and attended by "cloudy swelling and a tendency to exudation."

of the structural elements themselves of a part: or, to follow out the comparison, an actual growth of the sponge-substance. Induration, therefore, merely proves the previous existence of an organizable exudation, and therefore of inflammation in the part. Hypertrophy, on the other hand, is the result of active congestion, as will be shown further on.

The importance of all the preceding distinctions will appear when I speak particularly of the inflammations and congestions of the uterus; and the second cause of the confusion respecting them will next be considered.

Original Communications.

DIVISION OF THE ISTHMUS OF THE THYROID GLAND TO RELIEVE DYSPNŒA IN BRONCHOCELE.

By FRANK HASTINGS HAMILTON, M.D., LL.D.,

NEW YORK.

Sir G. Duncan Gibb contributes to the *Lancet*, London, Jan. 23, 1875, a paper on the subject of goitre, and the relief of impending suffocation by excision, or by division of the isthmus of the thyroid gland, in which he relates a case in which he had operated successfully.

The case is very interesting and instructive, and some of the remarks of the distinguished operator deserve to be repeated. He says that he had long been observing these cases, and that he had become aware of the fact that the gland occasionally encircles the trachea completely, specimens of this kind being found in some of the hospital museums. And in this way a young man at Oxford died of suffocation under his own observation, the condition of the parts being verified by an autopsy. Sir Duncan Gibb concluded, therefore, that the surgeon ought to anticipate the complete ligation of the trachea by the gland, and operate by incision or excision of the isthmus, when this condition was seriously threatened. A suitable case being presented in the person of a woman, æt. 29, who had a small goitre of two years' standing, and which had already begun to interfere with her respiration, Sir Duncan did not hesitate to operate at once. The patient being under the influence of chloroform, the isthmus was exposed by a vertical incision, two inches in length, when the projecting central portion was found to be about the size of a "flattened walnut." By the aid of an aneurism-needle a strong ligature was passed beneath the isthmus on either side. "The isthmus was then freed to the inner side of each ligature, divided, and wholly removed, the trachea being observed to be quite free. There was not much bleeding."

I do not think it is entirely plain, from the account as published, that any portion of the isthmus was taken away. The language, "divided and wholly removed, the trachea being observed to be quite free," might be construed to mean that the isthmus, being divided, withdrew to either side (and later in the paper he speaks of this having actually occurred), and was thus wholly removed from the trachea. But this is not material; the surgeon thought, and so do I, that, in some cases at least, a complete division of the isthmus is all that would be required, especially as the two lateral ligatures enclosing the isthmus must cause a complete, or nearly complete, destruction of what of the gland there may be between the ligatures and the median line.

The patient called upon Sir Duncan about four months after, in perfect health; she had married, and there was not a trace of the old symptoms. The gland seemed to have receded on each side from the median line, leaving the front of the trachea completely exposed.

Another somewhat similar case is then given, in which division of the isthmus was made, but the result was not yet determined.

The writer concludes by saying that he believes this to be "the first occasion in which the isthmus has been either wholly removed or divided," etc.

In the first edition of my Treatise on Surgery, published in 1872, occurs the following passage:

"Several years since I was called to a gentleman, who was suffocating in consequence of the pressure of a goitre. The gland was very large, and it was at first thought that a free incision of the sterno-cleido-mastoid —which was drawn very tense over the tumor on each side—might afford relief; accordingly this muscle was divided, but no relief ensued. I then decided, after consultation with several medical gentlemen present, to cut through the isthmus down to the trachea. With this view the isthmus was exposed, and a very strong ligature passed between it and the trachea, first upon one side and then upon the other; after which the isthmus was divided in the median line, until the trachea was laid bare. To my surprise, no improvement in respiration followed this operation. As the only alternative remaining, and as death from suffocation was impending, the trachea was opened in the lower angle of the wound and a tube introduced. He now breathed freely, but he survived the operation only three or four days. An autopsy was made, and the specimen, being removed, was sent to me. It was now seen that the gland had completely encircled the upper rings of the trachea, and that the trachea itself had undergone at this point a remarkable constriction, so that it would scarcely admit an ordinary goose-quill. In such a case, and perhaps in many others which may be presented, no operation but tracheotomy could be expected to prolong the life of the sufferer or to give even temporary relief" (p. 696).

Having no notes of this case, I wrote to Dr. B. S. Hovey, a distinguished physician, now residing in Rochester, N. Y., who was present and assisted at the operation, for further particulars, and have received his reply as follows:

"Rochester, N. Y., Nov. 2, 1875.

"My Dear Sir:—It is with pleasure that I answer your interrogatories of the 29th ult.

"The gentleman upon whom you operated was the Rev. E. H. Walker, aged about 50. The operation was made on the 8th of January, 1849. There were present Drs. W. H. Reynale, S. L. Endress, E. W. Patchen, L. M. Cook, and myself. I am not certain whether Dr. Blake, of Dansville, was present or not. The four first are dead. Mr. Walker lived after the operation three days and four hours.

"The autopsy was made by myself, and the specimen sent to you at Buffalo. You returned me a cast, showing very clearly what you state in your Treatise on Surgery. I can add no facts to what you have said in your description of the case, except that for three days before the operation an attendant was constantly required to hold that part of the gland which lay to one side of the trachea (I don't remember which) up from the trachea to prevent suffocation. In your operation you removed that part of the gland which

was held back by the assistant before you introduced the tube. This was done after the isthmus was divided, hoping to relieve the pressure on the trachea. The cast you sent me shows the trachea encircled by the gland, and its internal diameter no larger than you state.

"I am very respectfully,

"Your obedient servant,

"B. S. HOVEY."

A PORTABLE BOOK-RACK FOR THE USE OF MYOPIC CHILDREN AND ADULTS.

By WILLIAM SHAW BOWEN, M.D.,

OPHTHALMIC AND AURAL SURGEON TO THE HARTFORD HOSPITAL.

A FEW years since, when Dr. Cohn, of Breslau, in Silesia, published the results of examining the eyes of 10,060 school children* in the lower, middle, and upper schools of that city, his statistics attracted great attention, and students of ophthalmic science have become impressed with the extreme importance of the subject and the results thus shown. Dr. Cohn was induced to undertake this task from ascertaining, when revising the statistics of Prof. Förster's clinic, that 750 short-sighted people had presented themselves within four years, and that of these 750 over 400 had applied on account of severe annoyance dependent upon the refractive defect. The result of Dr. Cohn's investigations discloses the fact that out of the 10,060 children examined 1,004 were myopic. The tendency to short-sightedness increased as the scholars advanced from the elementary schools upwards. In the middle schools the proportion was one-tenth, and in the examination of the educational centre of the city, the University of Breslau, two-thirds of the students were myopic.

These investigations have since been pursued by other competent authorities in Germany; and Drs. Webster and Cheatham, of New York, Thompson, of Philadelphia, and E. Williams, of Cincinnati, have published valuable information as to the refraction of the eyes of school children in this country. While the proportion is not so large as in Germany, it is still sufficient to cause the question to be asked, What can be done to prevent the development and increase of this scourge, as it were, that is overshadowing our children and subjecting them to constant annoyance and oftentimes danger to future vision. Of course this subject is plain to the ophthalmic specialist; the general hygiene of myopia has been for a long time reduced to exact and simple principles, and by him communicated with emphasis to all myopes who come under his professional care; but the attention of physicians in general practice has not been adequately directed to the extreme importance of the matter; for they are the ones who are called upon in the great majority of cases for advice as to the proper regimen for the short-sighted child, who perhaps complains of pain and smarting of the eyes after a hard day's work over school-books, and by them the hygienic rules to be followed should be disseminated as widely as they disseminate the laws of health pertaining to proper ventilation, sewerage, and the care of the body. The demand for a higher and more rapid educational system are heard on all sides; it is typical of the race for life. The average American follows, and the so-called best and perfect schools are those in which the youth is forced to the utmost of his powers, the eyes sharing in the overwork as well as the mental faculties. The statistics of reliable observers show the results of this "forcing system," and nothing can be more conclusive than the results of Cohn's researches in Breslau. The writer has not systematically examined the refraction of all school children's eyes in this city, but in one room in an intermediate school nine out of forty-one were myopes.

The general hygienic rules to be followed by short-sighted children, and those having an hereditary tendency thereto, are simple,—such as parents can be made to comprehend. Proper illumination, natural or artificial, a moderate use of the eyes if myopia exists, and avoidance of the stooping or recumbent position while engaged in study or when using the eyes for near objects requiring convergence of the optic axis, together with suitable glasses, comprise the chief of these laws, and simple as they are it is astonishing how thoroughly they are neglected. Our school furniture, usually a subject of pride, on account of architectural neatness and elegance, is usually sadly deficient as regards the height of desks, the angle at which they incline, and the distance between them and the seats. Dr. Cohn examined the school furniture at the Paris Exposition, and found the American desks as deficient in these respects as those of European make, as he has shown in an article, "The School-houses at the Paris Exposition, from a Hygienic Point of View." The child is compelled to stoop and to bring his face close to the desk, in order to see the letters, the type of school-books being generally small and defective as regards clearness, and this stooping position and the straining of the internal recti muscles in efforts of convergence causes congestion, which may cause the refractive error, if an hereditary tendency thereto exists, or increase it if it already exists in an extremely moderate degree. Stooping and excessive convergence cause congestion of the tunics of the globe; congestion by mechanical pressure tends to increase the bulging at the posterior pole, thus increasing the myopia. Aside from the use of improper glasses, these two last are the most important factors in causing progressive myopia, and consequently to keep the head erect, to bring the book to the face and not the face to the book, should be the desideratum of all myopes.

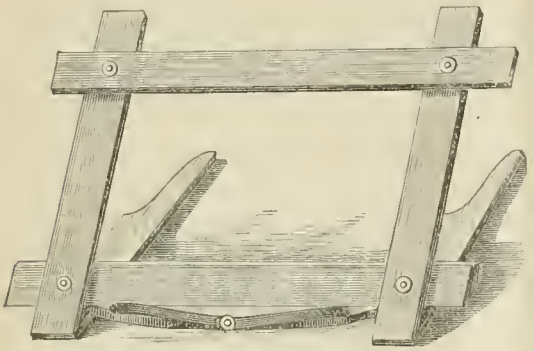
This, however, experience teaches, is exceedingly difficult to do. The child will not hold up the book; he becomes tired, and finds it is easier to lean over the desk where the book finds support. It is with difficulty that the adult myope of average intelligence can be induced to systematize the position of book or paper, although he may be the subject of progressive posterior polar atrophy, and its consequent fatal results to vision fully made known to him.

In considering this subject the writer has frequently imagined a school desk, which, by its strict regard for the hygiene of the eyes in the way of construction and in its relation to the seat, might avert in a certain degree some of the evils above mentioned. After careful inquiries of builders of school furniture, and of school committee-men, it was ascertained that any radical change of form, unless of such a nature that all could be uniform, would increase the cost of the article so as to prevent a ready sale. Economy of first cost enters largely into the consideration of the average school committee-man in fitting out his school room, and as a desk built on strictly hygienic principles would be an innovation of a marked character, it was impossible to find a manufacturer who could be induced to consider the importance of the subject sufficiently to build desks that would correct existing evils. A portable rack that can be adapted to any of the present style of desks has been made by a firm in this city,* that go s

* "Untersuchung. der Augen von 10,060 Schülkindern," Leipzig.

* O. D. Case & Co., School Furniture Manufacturers.

a long way towards aiding the accomplishment of one of the hygienic rules, viz., to enable the scholar to read easily and without fatigue, with the head erect, and to avoid the stooping position. The diagram shows the rack in position, and partially folded to



be packed away in the desk when not in use. It can be made at a very small cost, is provided with metal springs to keep the book in position, may be made at

any angle from the horizontal plane of the desk top, and is provided with rubber bands on its support to prevent noise in its motions when in use. They are useful for myopic adults as well as children, and can be used on the office desk and in the library, and when not in use can be folded and laid aside. It involves no new principles in its construction; it is the practical adaptation of old and well-established ones; is simple and not liable to get out of repair, and can be made at very small expense, so as to be within the reach of all.

HARTFORD, CONN., *Nov.* 1, 1875.

Reports of Hospitals.

BELLEVUE HOSPITAL.

NOTES OF PRACTICE AND PECULIARITIES OF TREATMENT.

CHRONIC BRIGHT'S DISEASE.

THE following is a summary of a plan of treatment recommended:

DIET.

This class of patients should abstain as much as possible from meat. The opinion was expressed that the excessive animal diet accounts for the great prevalence of the disease in this country. Milk should be substituted for meat, and should be associated with lime. Butter may be used; eggs if they agree, and fresh fish in the morning. Fried fats should be carefully excluded, but cream may be taken without stint. Vegetables and fruits are *always* good, but those should be selected which contain the least amount of woody fibre. Rice and potatoes, therefore, may be used, but asparagus, turnips, cabbage, and notably beans, which contain woody fibre in large quantities, should be assiduously avoided. Onions may be eaten with impunity, and are rather beneficial.

FOR THE ANÆMIA.

Iron should be administered from first to last, and by preference, the tincture of the chloride. This preparation is assimilated with difficulty, hence should not be given alone, but combined with nux vomica, and to this spirits of nitre may be added to assist the determination towards the kidneys. For example, ten drops of the tincture of the chloride of iron, ten drops of tinct. nux vomica, and one drachm of sweet spirits of nitre may be given three times a day.

Cod-liver oil increases the red corpuscles of the blood, because it is digested by the liver, and the product enters into them as an ingredient. The irritability of the stomach may make it troublesome to take, but it should be relied upon as much as in the treatment of phthisis.

TO COMBAT THE DISEASE ITSELF.

We have one agent which may be regarded as a specific against increase of connective tissue in the body, wherever the interstitial inflammation may occur, and that is the bichloride of mercury. It should be given in small doses, one-twentieth of a grain is the usual size, and should be combined with a diuretic to make it act upon the kidney. For example, one-twentieth of a grain of the bichloride, one grain of digitalis, and one grain of quinine may be given three times a day, with the result of producing a specific action upon the kidneys, and will *raise* the specific gravity of the urine.

ATTENTION TO THE CONDITION OF THE SKIN

will materially assist the embarrassed kidneys, and to do this we may have recourse to two things. If excessive œdema is present, the pressure produced shuts off the circulation to a great extent and prevents removal of the fluid by diaphoresis. It is much better then to make punctures in the distended skin of the legs, and let the water drain away at once. No apprehension need be had with reference to this trifling operation, if the limb, when the punctures have been made, is wrapped with cloths wet in a solution of carbolic acid in water, to which has been added essence or oil of cinnamon. The latter is to correct the smell of the carbolic, and is also equally antiseptic.

The second thing is, to rub the patient all over once a day with sweet oil. If extra diaphoresis is desirable, it can be best obtained by placing a blanket in an empty bucket, pouring hot water upon it, for in this way much less water is required, and then wringing it out and quickly applying it around the body and covering it with a dry blanket. The skin should be well oiled before the blanket is applied.

Such was a brief outline of the general treatment for this class of cases, and may be suggestive in certain particulars.

PROGRESSIVE MUSCULAR ATROPHY.

The interest in this case was the *limitation* of the atrophy, for it affected chiefly, almost exclusively, the extensor muscles of the thigh. There had been simply a gradually increasing weakness of these muscles going on during the past thirteen months without loss of sensibility or pain. The thigh affected, the right one, measured 17⅛ in. in circumference, while the unaffected thigh measured 19¼ in. Below the knee the muscles seemed very good. There was no evidence that the man had ever suffered from disease of the spinal cord, unless the present condition is regarded as due to some degeneration of the anterior horns, but there was no evidence of pre-existing meningitis, myelitis, etc., nor had there been any tremor or peculiar pain. There

was no evidence of peripheral paralysis, nor was there any evidence of tumor producing pressure.

CARCINOMA OF THE STOMACH.

In this instance the patient complained chiefly of pain in the hip and back, until her attention was drawn to other symptoms, when she admitted that she vomited quite regularly about an hour after each meal, if she ate anything besides gruel and whey. She was forty-two years of age; there was no hereditary taint with malignant disease, so far as could be ascertained, and she had never suffered from any sickness except the present, which began eight weeks ago. Upon examination, a tumor, about the size of a hen's egg, was found in the region corresponding to the usual situation of the pyloric extremity of the stomach. The woman did not suffer very much pain referable to the stomach, nor had she ever vomited blood or coffee-ground material.

But cancer of the stomach may be present without producing pain, and it sometimes occurs without vomiting, a fact which is often overlooked. When the cancerous disease is situated in such positions as not materially to interfere with the movements of the stomach, or is outside of where it will produce obstruction, vomiting may be absent.

EPILEPSY.

The chief feature of interest in this case was the fact that the woman, forty-five years old, had had epileptic fits once in about six weeks since she was ten years of age, and they had not given rise *to any very marked impairment* of her mental faculties. The case was perhaps an exceptional one.

DISLOCATED LIVER—CIRRHOSIS WITH ENLARGEMENT.

This was a case of liver disease of considerable interest, and the history is briefly as follows:

A male patient, æt. 42 years, German, was admitted to the hospital, May 7, 1875. The chief points in the clinical history were the occurrence of piles with frequent desire to go to stool, soon followed by bleeding from the gums, and these by loss of appetite, flesh, and strength. Some time after, he suffered from general anasarca and ascites, and finally from an attack of jaundice, but this had nearly disappeared. In June, 1875, he first noticed a swelling in his abdomen. The general anasarca had nearly or quite disappeared at times, but this had always occurred while the patient was in bed. The reason for this is probable when the condition of the tumor in the abdomen is considered. The abdomen at the time of the visit was very much increased in size, part of which was due to the presence of fluid, but in addition to that there was present a solid body, slightly nodular to the touch, sharp in outline at its lower border, which could be moved about very easily. From percussion and other means of examination, it was very evident that this body was the liver, and that it was dislocated downwards two and a half or three inches. At one time its free border had reached nearly to the umbilicus. It could be easily restored to the normal position of the liver, but returned at once as soon as the mechanical support was removed.

The vertical measurement of the organ as now situated in the abdomen was eight inches, which was one and a half inches less than when admitted to the hospital.

The question arose, Is the liver really increased in size? The increase in size was doubtful, although at first thought apparent, for the liver was not only dislocated downwards, but the normal convexity of the organ, instead of being applied to the concavity of the diaphragm, was applied to the abdominal walls, and the surface which could be measured was not the anterior border, but the convex surface.

The diagnosis of cancer had once been made, but the progress of the case had proved its incorrectness. The history was rather that of cirrhosis, and it was regarded as a case of cirrhosis of the liver, in which the liver in the *advanced stage* of this disease was *increased*, rather than diminished in size. There was no evident cause for this condition of the liver in this patient, for he had been a rather temperate man; gave no history of specific disease, and had not been subject to any of the causes which favor displacement of the liver in the female.

Progress of Medical Science.

THE QUESTION OF THE CONTAGIOUSNESS OF HEREDITARY SYPHILIS.—Dr. J. Caspary, of Königsberg, offers some facts in support of the opinion which he holds, adverse to that maintained by Dr. Carl Günzburg regarding the contagiousness of inherited syphilis. Dr. Günzburg's observations were made in the Foundling Asylum at Moscow, and were to this effect. In this asylum is a separate department to which all children are sent as soon as they show evidences of syphilis. The nurses, although warned of the risks they run, often voluntary continue to give the breast to these children after removal to this department. Thus in the years 1868, 1869, and 1870, 120 children who had hereditary syphilis were nursed by thirty-one nurses for periods varying from six months to two years; no woman nursing less than two, and some as many as sixteen different children. And yet no one of these wet-nurses contracted syphilis. Caspary maintains, with regard to this, that a single positive case of infection should have greater weight than any amount of negative testimony such as this. He finds such a positive case quoted in the critical part of Günzburg's work, from Le Barillier, of Bordeaux. It was as follows: A healthy woman, with an abundance of milk, entered the Children's Hospital at Bordeaux, as wet-nurse, fourteen days after her confinement. All the children whom she nursed continued healthy. On October 1, 1859, she was given to nurse a child, four days old, and supposed to be healthy. It developed thrush, and the nipples of the wet nurse became sore in consequence, and on the twenty-fifth day the child had syphilitic ecthyma, followed by other manifestations of syphilis, and died on Nov. 19. The sores on the nurse's nipples developed into ulcers, and she soon showed various other manifestations of syphilitic infection. Günzburg's interpretation of this case, however, is that the wet-nurse was already the subject of latent constitutional syphilis, contracted sore nipples only from the child with thrush, which became ulcers and foci of infection for the child, and were followed by the outbreak of general symptoms in the woman. Caspary also supports his own view of this case by other arguments, for which we have not space. He then gives the following case, which was in part under his own observation. A healthy married woman, of thirty-four, who had had and nursed two healthy children of her own, in the spring of 1869 took to nurse an illegitimate child, which had an eruption at

the anus and mouth, which the physician soon recognized as syphilitic. While nursing this child the woman became pregnant, noticed a sore on her breast, developed general syphilis, was successfully treated in the fifth month of pregnancy by inunction, and on March 4, 1870, gave birth to an apparently healthy child. The husband remained free from infection. The child, however, on April 14th, was found to have syphilitic roseola, and died the next day. At the autopsy the cause of death was made out as bronchitis, but in the liver was found a general increase of the interstitial connective tissue, corresponding with the description of Bärensprung. Caspary also adduces a case where a syphilitic illegitimate child, taken to nurse by a healthy married woman, communicated the disease to her through primary sores upon the nipple; and later her husband and her own child, both of whom were previously healthy, were infected. He then brings forward this argument, viz.: If inherited syphilis is not contagious, there must be such an essential difference between it and the acquired disease that the system, when infected with the former cannot be assumed to be protected from the latter. He therefore inoculated, with the secretion from ulcerated papules in a case of acquired syphilis, two twin children, who were the subjects of inherited syphilis. The result was negative in each case, as he had anticipated. It so happened that he was consulted at the same time by a previously healthy married woman, living in the same house with these children, on account of a sore on her nipple, and this proved to be a chancre, contracted by nursing one of these very twins, she having an excess of milk over what was needed by her own healthy child. The woman soon showed many of the ordinary manifestations of constitutional syphilis. He has satisfied himself of the accuracy and completeness of the case reported. In view of these facts he therefore does not hesitate to express his belief that the contagiousness of inherited syphilis is proved, and that the opposite views of Günzburg are erroneous and dangerous.—*Berl. klin. Woch.*, Oct. 11, 1875.

Nervous Cough as a Reflex Symptom of Anteversion of the Uterus.—Dr. Malachia de Cristoforis reports the following case: A lady of twenty-three had suffered for a long time from a nervous cough, having these peculiar features. It occurred only in the day-time, disappearing as soon as she lay down, whether at night or in the day-time. There would be a series of eight or ten dry coughs, followed by half an hour's quiet. She had also suffered for a year from frequent micturition and a dragging sensation in the lumbo-sacral region. Various nervines had been tried ineffectually. Her history was, that her first and only pregnancy, two years before, had resulted in an abortion at three months, and had been followed by some persistent leucorrhœa and lumbo-sacral pain, aggravated by standing and walking. On examination, the larynx, chest, and abdomen were found free from disease, nor was there any sensitive point in the spine; there were two painful points in the face, however, referable to the trigeminus. On making a vaginal examination, the uterus was found enlarged and anteverted, so that the body lay behind the pubic bone and the cervix pressed against the sacrum. These abnormal relations were remedied on her assuming the horizontal position. A double curved Hodge's pessary was introduced, which restored the uterus to its normal position, and the cough was relieved, to return, however, when, by way of experiment, the pessary was temporarily removed after a few days. After a year it was no longer required. The author's theory is, that these reflex symptoms may have arisen from pressure of the body of the uterus upon the bladder, from traction upon the utero-sacral ligaments, or from pressure of the cervix upon the posterior sacral plexus or its branches—perhaps all three reasons combined.—*Ann. Univers*, cexxxi., p. 519, *Marzo*, 1875.—*Schmidt's Jahrb.* Sept. 8, 1875.

Indications from the Fluid of Exploratory Punctures.—Dr. H. Westphalen lays down the following rules for our guidance in examining the fluid obtained by exploratory punctures of abdominal tumors.

1. The more viscid a fluid, and the more incompletely its albuminates separate, so much the more surely is it to be regarded as ovarian. 2. If no coagulation forms after such a fluid has stood for some hours in a warm place, or after its mixture with previously tested blood serum, it is highly probable that it comes from an ovarian cyst. To this there are, however, exceptions. 3. The indications derived from the precipitation by alcohol, and from the form of the coagulum, are of but little value. 4. The microscopic examination of the sediment should be chiefly for cylindrical epithelium, and in the absence of this for colloid and granular globules. 5. If these tests fail us in the case of a very thin fluid, the coagulation test is most to be depended on. The suspension in the fluid of fine particles of coagula, formed by acid, and the difficulty of clearing it by filtration, also point to paralbumen and metalbumen and an ovarian origin.—*Archiv für Gynækol.* viii. 1.—*Berl. klin. Woch.*, Sept. 27, 1875.

Puerperal Inflammation of the Ilio-sacral Articulations.—At the session of the Society of Gynæcology of Berlin, held March 16, 1875, Dr. Ebell reported that he had seen two cases of the disease mentioned. One was in a patient twenty-four years of age, with a contracted pelvis, a primipara, who was brought into Martin's clinique after attempts had been unsuccessfully made to deliver her with the forceps. She died of a low grade of inflammation of the joint, with necrosis. The second case was a woman of thirty, who was seized with severe pain in the left hip on the seventh day after an unaided delivery. Soon she could not walk, and lay on the right side with the left thigh permanently adducted and rotated inwards. There was doughy swelling of the soft parts covering the joint, and rectal examination revealed the same condition of the anterior surface of the sacro-sciatic articulation. Temperature a litte over 103° F. The treatment consisted in rest, painting with tincture of iodine, and compresses of water. Complete recovery ensued.—*Berl. klin. Woch.*, Sept. 27, 1875.

Koumys.—M. Landowski recently made a communication to the Association française pour l'Avancement des Sciences, on the value of koumys in consumption. It was stated that beside albuminoid matters, the liquid contains salts identical with those of the serum of the blood, alcohol, and lactic acid. L. cited a number of cases of consumption where koumys had been employed with the greatest success. He recommends an extract prepared as follows: Good koumys, rich in ferment, which has been deprived of caseine, is condensed in a vacuum, at a low temperature. After the evaporation of the liquid the lactic and alcoholic ferments remain, to which is then added alcohol obtained from the distillation of old koumys. Adding a little lactate to it the preparation of the extract is complete. It is a syrupy liquid, of an uncertain color, greenish white, and opaque. Forty to forty-five grammes added to one litre of milk are sufficient to change it in forty-eight hours into excellent koumys.—*Lyon Médical*, Oct. 3, 1875.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

PUBLISHED BY

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, January 1, 1876.

THE SALE OF PATENT MEDICINES.

We recently referred to the questionable course pursued by pharmaceutists in virtually declining to abandon a profitable traffic in patent and irregular medicines, on the ground that they were in popular demand. We then, very pertinently as we thought, propounded the inquiry whether, under such circumstances, pharmacy could strictly be considered a profession, or whether it should not rather be classed among the commercial pursuits, inasmuch as the sale of such articles for mere pecuniary purposes savored more of the characteristics of trade than of high professional duty. We are glad to find, in the columns of the *American Journal of Pharmacy* for December, that the remarks we then made have not escaped the notice of the pharmaceutists of the country, almost all of whom have been guilty, in greater or less measure, of the practices referred to. We find our remarks not only honored with editorial notice, but also with a special paper offered at a meeting of the New York Alumni Association of the Philadelphia College of Pharmacy, and which we republished in our last number. Both these articles seem to confirm rather than refute the main positions we then advanced. The point in our own editorial of October 9th, which seems especially to have suggested these replies, is the allusion we at that time made to "over-sensitiveness of the pocket-nerve," as the chief motive power influencing the actions of the pharmacists in their wrong-doing. In the paper referred to, there is no contradiction of this insinuation, but rather an apology for the false status of pharmacy on the subject. Our criticism on their course is, however, said to be "most unkind and unjust to the respectable minority of the profession [of pharmacy], who regard this feature as a nuisance, and would gladly aid in its discontinuance." We do not doubt that there are many apothecaries of excellent principles who do see the impropriety of this irregular traffic, but men must be judged by their deeds and not merely by their professions. What is this "respectable minority" actually *doing* to effect the discontinuance of a practice which is acknowledged to be fraught with evil? Absolutely nothing, so long as the sale goes on unrestricted at their counters, and patent and special medicines are meted out to every indiscriminate applicant. We confess to an unlimited faith in the adoption of radical measures for the suppression of radical wrongs; we consider therefore that a bold front on the part of representative State and national pharmaceutical associations will have the effect of strengthening the hands of this respectable minority; and of guiding into paths of propriety the great majority, who, in their practices at least, are not so respectable.

But the author of the paper in the *Journal of Pharmacy*, and the editor of the latter, who is also Permanent Secretary of the American Pharmaceutical Association, are strenuous advocates of half-way rather than of extreme and thorough measures. The former maps out a line of duty for pharmacists to follow that is beautiful in its simplicity, and would be admirably practical in its working, if druggists were not human in their weaknesses, and were absolutely perfect as patterns of self-denial in their pecuniary dealings. When the millennium arrives we shall expect every pharmaceutist to frame his course of action according to the following standard there proposed: "His [the pharmaceutist's] duty is: Never to recommend a patent medicine, keep no advertising matter setting forth their merits, allow no display of signs and show-cards, etc., in his shop; and, if possible, as it often is, keep such nostrums out of sight of the public, to supply only on customer's order, provided he cannot prevail upon him to consult a physician, or to try some remedy which he shall prescribe." We presume by "he," is meant the apothecary, who would thus substitute one wrong for another by trying to induce a customer not to purchase a nostrum of whose composition both are ignorant, and then violate his own code of ethics by himself prescribing for the patient. The fancy picture of an apothecary attempting to argue with a purchaser on the impropriety of his using medicines which are kept regularly in stock for any caller, and employing all his powers of gentle persuasion to induce the patient to consult a medical man, may have its counterpart in actual practice in one case in a thousand, but in the other nine hundred and ninety-nine cases the buying and selling of irregular medicines is a much simpler and more monetary process. We believe, however, that there is some show of conscientiousness evinced in the proposed hiding from sight of medicines, of which he is confessedly ashamed to be the seller, and for this much at least let us be thankful. The editor of the journal quoted believes that the best way to abate a nuisance is to educate the public; on the contrary, experience in measures of sanitary relief of other kinds

has clearly proven that while the process of educating the public is being discussed, the offence still endures in all its original enormity. The pharmacist, in the case in point, is really responsible for the spreading of the very nuisance which he professes a desire to do away with; a course of apparent duplicity of action that tends rather to perpetuate it. As long as the nuisance remains, the moral atmosphere cannot escape contamination. But why adopt the editor's suggestion and attempt to educate the public at all, if it be true, as the author of the other paper flatly asserts, that the nostrum-buying public are not, as we had represented, the "non-educated portion of the community," and that "among the patrons of certain nostrums are numbered many of the best educated people, notably the clergy, who have an unaccountable propensity for endorsing nostrums."

After all, it is the question of the pecuniary effect of the sale of these medicines that is the stumbling-block in its solution. All respectable pharmaceutists agree that it is an evil; but some of them differ with us in the mode of discontinuing it. It is a source of great profit, even if it be a moral wrong; and it is probable, therefore, that apothecaries can never be unanimous in any plan for its abandonment. It is none the less an evil because physicians sometimes prescribe these proprietary remedies; nor, does it justify a wrong on the part of the apothecary in selling them that his refusal to do so "would only send the customer to the next drug-store," or lead to the establishment of agencies for the tabooed preparations at other places of business. Let him be just and honorable to himself and the public; he has no further responsibility, be the effect what it may. But a determined opposition to the traffic on the part of the profession of pharmacy for so we would wish to call it—would be likely to induce the right-thinking portion of the public to reflect that there must be some valid reason for all this self-abnegation. As it is very desirable that pharmacists and practitioners should be in practical accord, we shall be glad to hear of any feasible plan of conference between pharmaceutical and medical conventions that will secure greater stringency of legislation, and suggest satisfactory methods of remedying the evils alluded to.

THE PRESBYTERIAN HOSPITAL AFFAIR.

We are officially informed that the *Presbyterian Hospital*, on the 13th December, contained forty-five patients, that the managers were under the necessity of opening two more wards, and that there were also *eleven candidates* for the vacant places in the medical staff. There are then eleven men at least who advocate the principle of being dismissed from a hospital staff without cause, and who are willing to trust themselves to the tender mercies of a board of managers who have defiantly outraged all notions of even ordinary justice. If this is the way to uphold the dignity of our profession we have been wrong from the beginning, and entirely misinterpreted the popular sentiment.

THE SECULAR PRESS ON MEDICAL TOPICS.

It is amusing to see the audacity with which the secular press tackles abstruse questions in scientific medicine. Not content with the exercise of its influence in the direction of educating the people on health matters within the comprehension of all, it goes so far beyond the latter point, that even the educated physician stands aghast at the profundity of its judgment. But, after all, this is in keeping with a self-appointed censorship of all the doings of mankind, the medical profession included. If a new remedy is reported, an opinion must be expressed upon it: the same with some new method of treatment, or some new medical doctrine, and it is done in that authoritative way which is ridiculously refreshing On questions of medical ethics we must look to them for guidance, and, refusing to accept their right to dictate, we must be ridiculed into submission. Lately we had a discourse on vivisection, which, in the novelty of the views advanced and the soberness of the advice offered, was more than usually entertaining. Just now the topic of criminal insanity is occupying the attention of one of these medical authorities, and after reading what he has to say upon the Staudeman case, we are filled with regret that he was not consulted by the lunacy commissioners before they made their report.

THE LATE DR. KRACKOWIZER.

So seldom is justice done to the memory of the great and good men in medicine, that when there is an exception to the rule of burying their deeds with their bones we make due notice of the fact. No more appropriate exception could have been made than in the case of the lamented Krackowizer, an elaborate and graceful memorial of whom has lately been published.*

If our lamented friend could in his natural modesty have supposed that his life deeds were worth recording after he was no more, he could scarcely have selected more judicious and eloquent biographers than his old friends Drs. Jacobi and Althof, and the Hon. Carl Schurz. The addresses of these gentlemen are contained in the volume before us: the one by Dr. Jacobi, delivered before the Academy of Medicine; the other two at the Memorial meeting in Steinway Hall, October 22. At the same meeting were also addresses by E. F. Hall, Esq., and Dr. F. Zinsser. These, together with the resolutions passed by the different societies of which the deceased was a member, and the various public institutions with which he was connected, make up the contents of a volume which cannot fail to be acceptable to all who knew the deceased. The life

* In Memory of E. Krackowizer, N. Y. G. P. Putnam's Sons, 1875. 8vo. pp. 68.

sketch by Dr. Jacobi is particularly eloquent in loving admiration of his old and well-tried friend—and yet the whole story is not told.

Reports of Societies.

NEW YORK MEDICAL LIBRARY AND JOURNAL ASSOCIATION.

Stated Meeting. Dec. 17, 1875.

DR. E. G. LORING, PRESIDENT, IN THE CHAIR.

NÆVUS.

THE discussion upon the above subject, it being a special order, was opened by DR. BAYLIS.

The doctor gave a brief *résumé* of the ordinary descriptions given to the different varieties of this affection, and then turned the discussion in the direction of treatment, as probably being the more interesting part of the subject. To induce atrophy of these growths resort has been had to a variety of measures, such as compression, astringents, acupressure, ligature; different measures for exciting inflammation in the tissue, such as setons, puncture, laceration, incision, insertions of sponge, injections of stimulant solutions, puncture with probe coated with nitrate of silver, vaccination, ligature in different ways, cauterization, etc., etc.

DR. GARRISH regarded needles heated to a white heat as the best means for treating nævi of moderate size which had a solid base. He had treated one case successfully by vaccination, when the tumor was situated over the anterior fontanelle.

DR. R. W. TAYLOR remarked that the nævus araneus, or that variety in which there is a central red point, from which little vessels radiate in all directions, especially liable to occur about the nose and upper part of the cheek, can be very easily destroyed and cured by the use of the electric needle.

Again, that variety, or subcutaneous form, of nævus which is sometimes found in the cheek, and simulates in feel a fatty tumor, can usually be benefited by this method of treatment. In the treatment of this variety he had hesitated with regard to injecting ergotine or other substance with the view of producing coagulation of the blood, for fear that subsequent trouble might be experienced in the way of cerebral embolism. The common red-hot needles give so much pain that the patient flinches when they are introduced, and then they are cooled before they have time to reach the proper part of the growth. In this respect, then, electric needles are far superior. They are easily applied, and the subsequent results in the way of cicatrices are almost nothing, for the puncture closes rapidly, and the spot can scarcely be recognized where the needle was introduced. Where the ordinary needle has been employed the instances are not few in which minute keloid growths have appeared in the cicatrices. Dr. Taylor also referred to a case of traumatic nævus occurring upon the nose, and believed such an origin to be uncommon.

DR. A. C. POST remarked that the most important distinction to be made in this affection is between the vascular and the pigmentary varieties. Stains of the skin are mere matters of personal blemish, are without tendency to increase, and cause no trouble aside from the discoloration.

The superficial nævi of the vascular variety are easily cured by either of the prominent methods of treatment in ordinary use. When the surface of the nævus is flat it can be treated quite satisfactorily by brushing it over with nitric acid, just enough to produce a slight superficial cauterization.

If there is no tendency to spread, the nævi, perhaps, may better be left without treatment, but when they manifest a tendency to spread, treatment should be at once introduced.

If needles are employed, blunt-pointed ones should be selected, for it is the chemical action of the heat that we wish to secure, and not the mechanical action produced by a sharp needle. The doctor exhibited an instrument devised by a former graduate of the University Medical College, which consisted of six needles, each about the size of a fine knitting-needle, and without points, inserted in a handle, and about half an inch from their outer extremities they passed through a bar containing two rows of holes. Each row contained three needles, and the perforations were separated nearly one-fourth of an inch in each direction. By using this instrument the operation can be greatly facilitated, and the heat is better retained in this bundle than can be done by a single needle.

When the tumor is quite prominent the most desirable method of treatment is by means of the ligature. The tumor may be ligatured in halves, or more divisions can be made, according to circumstances.

The deeper subcutaneous nævi, composed largely of veins, the doctor looks upon with some apprehension as regards ultimate results obtained by treatment.

Reference was then made to one or two cases which had been treated for him by Dr. Beard, of this city. The treatment was by means of electrolysis, and good results were obtained. The three methods of treatment for nævi which Dr. Post recommended were the needles, the ligature, and electrolysis.

DR. F. P. FOSTER gave the history of his own case, and exhibited the spot where the nævus was situated. It was upon the forearm, was congenital, was diagnosticated as a fatty tumor by Dr. Bigelow of Boston, who proceeded to an operation for its removal. When a long incision was made, the mistake in diagnosis at once became evident.

Dissection was then made around the base of the tumor and about thirty vessels ligatured, which contributed to its vascular supply. After a tedious and alarming illness, during which the question of amputation was raised, he made a good recovery.

DR. B. F. DAWSON remarked that he was well convinced that the treatment of nævus should be restricted to two methods—namely, electrolysis and treatment by the use of the galvanic cautery. The doctor objected to the use of needles, because they cannot be heated sufficiently intense to retain their heat until they can be thrust into the tumor to the depth desired. Another objection is the discoloration of tissues produced by the oxidation of the needle. Objection was also made to the use of any agent which coagulates the blood, hence all caustic applications and injections of astringents, stimulants, etc., etc., were excluded. The favorite plan of treatment employed by Dr. Dawson is that by means of the galvanic cautery, and to use this in the most successful manner a few precautions are necessary. For the superficial nævi all that is required is such a degree of heat as will radiate into the deeper tissues from the surface. If too intense heat is used, it will be removed with the needle or knife, or platinum strip, whichever may be em-

ployed, and the appearance of the nævus will subsequently be the same as it was before the application, whereas if the platinum is heated only to a dark-red color, destruction of tissue will not be produced, and the vessels will be made to shrink on account of the effect produced by the radiated heat. For all superficial nævi of moderate size a single thorough application is all that is required to effect a cure. In treating the subcutaneous tumors a white heat becomes necessary, in order that the knife or needle shall retain sufficient heat to be of service when it has reached the deeper tissues.

With regard to nævi having large surfaces, portions may be destroyed at different times, and considerable portions will also be destroyed by the moderate inflammatory action which follows the operation. Dr. Dawson also related a case where the nævus was situated directly over the anterior fontanelle, and was treated successfully by means of this method. The dangers were recognized, and a corresponding degree of care exercised in performing the operation.

The point specially insisted upon by Dr. Dawson was, that the galvanic cautery did not in any true sense produce a coagulation or thrombosis in the vessels like that produced by an astringent injection, but rather a clot which becomes rapidly organized and a shrinking in the calibre of the vessels which remains permanent, and that this can be effected without destruction of tissue. If too hot a needle or knife from the galvano-cautery is introduced into tissues there will be as much hemorrhage as after the use of a cold sharp knife.

Dr. Allen spoke of the galvanic cautery as the most serviceable means at our command for the treatment of nævus. The ease with which it can be applied, the rapidity with which the operation is performed, and the almost total absence of severe inflammation following it, strongly favor its adoption.

The doctor then referred to three cases occurring in young children; two upon the head and neck, one upon the wrist, and all in active growth.

Those upon the head and neck were cured by a single application. That upon the wrist required a little more prolonged application. In the superficial variety, all that is necessary is to place the platinum, moderately heated, in contact with the surface, and allow it to remain sufficiently long to be certain that the heat has radiated to the tissues below.

Dr. Andrew H. Smith referred to a variety of nævus which has a fibrous capsule, and the contents can be enucleated almost as easily as an encysted tumor can be removed. Perhaps in this variety enucleation would be the best treatment. The doctor also spoke of the nævi which are sometimes seen at the alæ of the nose, and appear to involve the entire thickness of the alæ. He inquired whether this variety can be treated by the use of the galvanic cautery in the same manner as when the nævi are situated in other localities.

Dr. Dawson replied that such nævi could be treated by this means equally well as those found in other situations.

Dr. Messenger mentioned a case of what is known as the port-wine nævus, that fell under the care of a quack, who nearly cured it with a sun-glass.

Dr. Piffard remarked with reference to the solar cautery, that he had found it applicable in the treatment of lupus and chancroids, and could not see why it might not be serviceable in the treatment of nævus. While applying this cautery, it is well to protect the eyes from the brilliancy of the light by wearing colored glasses, else the operator will not be able to determine the *exact* outline of the cauterization. With a little practice a line no more than one-sixteenth of an inch in breadth can be obtained with considerable ease. The doctor referred to a case of nævus situated over the anterior fontanelle, in the treatment of which he assisted Prof. Darby. The galvanic cautery was employed, and the result obtained was satisfactory as far as applied. The nævus was of some size, and only a portion was destroyed at the first operation.

Dr. Ward referred to cases where he had effected a satisfactory cure by the use of the common hot needles. The result desired in the use of the cautery is the production of a clot in the vessels, which shall rapidly become organized, as after a ligature, and be followed by permanent atrophy. By the use of the galvanic cautery localized coagula are not produced, but coagulation over the entire tumor is produced at once; hence there is no *vis a tergo* left in the tumor to drive fragments of the thrombus forward. The doctor recommended the galvano-cautery, but at the same time justified the use of the actual cautery by means of the hot needles or hot iron when no other apparatus can be obtained. He objected to the practice of injecting coagulating substances into nævi, for the reason that great risk is taken with reference to the subsequent development of embolism.

The hour of ten having arrived, the Association was adjourned by the President.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, December 16, 1875.

Dr. S. S. Purple, President, in the Chair.

THE TREATMENT OF PERITYPHLITIC ABSCESS

Being the subject for discussion, Dr. Weber related in brief the histories of three cases. The first occurred in 1869, in a boy æt. 18 years, and presented the ordinary symptoms of this affection. Dr. Willard Parker, of New York, had reported his case and method of operation in the year 1867. Dr. Weber performed his operation in the same manner, and made a long incision over the region of the suspected abscess, carefully dissecting through one layer after another of the abdominal parietes until the fascia transversalis was reached. At this point, a careful search for fluctuation was made, but none being detected, it was deemed unadvisable to proceed further with operative measures. Accordingly a drainage tube was inserted, and the wound closed, except the central portion. Only a short time elapsed before the abscess ruptured, and upon the second day a foreign body, a hard lump of fæcal matter, was found outside upon the dressing. The drainage tube was retained for a short time, and the boy soon made a perfect recovery. In this case the operation was performed upon the *seventh* day, and scarcely any connective tissue was discharged from the wound.

Dr. Weber's second case occurred in a young man æt. 25, who was quite fleshy and robust. The attack was sudden and violent. There seemed no difficulty in diagnosis, and the case was treated with opium fomentations, etc., until the *eighth* day, when, after being able to distinctly recognize a tumor, it was determined to perform the operation for evacuating the contents of the supposed abscess. Accordingly an incision about four inches in length was made through the abdominal parietes, and extended down to the fascia transversalis. At this point, as in the preceding case, the fascia was palpated in search of fluctuation, when suddenly the wall of the abscess was perforated, and a

large quantity of fetid pus escaped. The case did well for a time, and within two or three days an orange seed covered with fæcal matter was found upon the dressing. After a time, considerable connective tissue was discharged from the wound, and it was at least four weeks before union began to take place. In the fifth week the patient became the subject of traumatic erysipelas, which involved the right side of the trunk, invaded the wound, separated the lips, and delayed final union for a very considerable length of time. Union, however, finally took place, but the cicatrix seemed so insecure, that the doctor thought it advisable for the patient to wear a truss as a guard against the occurrence of ventral hernia. Hernia has not occurred, and the man wears the truss without serious inconvenience.

Dr. Weber's third case occurred in a tall lank individual who had syphilis, and was 28 years of age. He was suffering from *secondary* manifestations, mucous patches, etc., at the time of the attack, which came suddenly in the night and developed the peculiar symptoms of the disease. Leeches, fomentations, opium, injections of warm water to relieve flatulence (tympanitis was marked), beef-tea, milk, and stimulants were the agents resorted to in the early treatment of the case. On the *ninth* day it was determined to perform the operation, and accordingly an incision, as in the second case, was made through the tissues over the tumor down to the fascia transversalis. Here again, while palpation was being made, the finger broke through the wall of the abscess and a large amount of fetid pus evacuated. In this case the amount of suppuration following the operation was very large, but no foreign body was discovered. At the end of the second week there was a sudden and marked aggravation of symptoms, characterized by pain, dysuria, restlessness, tympanitis, acceleration of pulse, elevation of temperature, etc., etc. These symptoms were relieved as much as possible by the use of opium, the catheter, fomentations, injections, etc., etc., until at the end of the third or early in the fourth week the patient began to pass pus in considerable quantities with his urine, and this continued for about a week. The wound in the abdominal parietes during this time continued to discharge freely. With the discharge of pus by the urethra there also came relief from all the severe general symptoms.

In the fifth week the doctor was again summoned in the night on account of a second aggravation of symptoms. The constitutional disturbance was about the same as before, and was relieved as far as possible by the use of the same measures. At the end of about a week the patient passed a large quantity of pus by the rectum, and again the patient felt relieved. Finally, about the eighth week, the external opening had closed, but the cicatrix presenting the same weak insecure appearance. As in the second case, it was recommended that a truss be worn as a protection against the occurrence of hernia. In this case also hernia has never been developed. The question which the doctor now raised for himself was, How shall I perform the operation in the future? He formulated his answer thus: there are, undoubtedly, cases which admit of first introducing a fine canula or needle into the abscess through the abdominal walls, and thus make the instrument a guide for the subsequent incisions, according to the method of operative procedure described by Dr. Gurdon Buck of this city.

Perhaps, however, the incision enables the operator to be more sure of fluctuation beneath the fascia transversalis, and that is really the great point of importance in the operation. An incision four inches in length the doctor regarded as amply sufficient. Dr. Weber emphasized another point, namely, that in another case he shall treat the wound after the antiseptic plan of Lister, or any other well approved plan, for the purpose of destroying the atmospheric germs with which it may become poisoned. The plan of operation by first making an explorative puncture was not objected to by Dr. Weber, and perhaps there may be less liability to subsequent development of hernia than when a free and somewhat extended incision is made through the abdominal walls. In any event, he objected to delaying the operation beyond the eighth or ninth day.

Dr. Fordyce Barker remarked that he was not able to speak of this disease as an idiopathic affection, but his observations had been confined almost exclusively to those cases which have been associated with the puerperal state. He had seen a single case associated with typhus fever.

In this connection, the doctor referred to the well-known tendency, in certain epidemics of puerperal fever, to the formation of abscesses in various regions of the body. In some epidemics, the occurrence of such abscesses seems to be the most notable lesion, and for this reason perityphlitic abscesses are seen not infrequently.

Reference was here made to the great difficulty of diagnosis of this affection in puerperal women, because of the obscurity of the symptoms. It is difficult to determine whether we have to deal with pelvic peritonitis or pelvic cellulitis, or metritis, or phlebitis, and it is only by the most careful study of the clinical symptoms, accompanied by the most careful and judicious physical examinations, that a correct differential diagnosis can be made.

Certain points in diagnosis observed by Dr. Barker may be mentioned. Tumefaction of the abdomen is especially liable to be absent in women sick with puerperal diseases affecting this region.

Where this form of abscess has been the primary manifestation, he had not found that high degree of temperature and rapidity of pulse, perhaps none of the symptoms except tenderness upon pressure, which commonly accompany puerperal peritonitis. The temperature does not usually rise above 103 or 104 F.; the affection is ordinarily of slow development, and the pulse may reach 108 or 110.

There is not that amount of constitutional shock commonly seen in connection with metritis and phlebitis.

Vomiting is a prominent symptom. Difficulty of micturition has been present in every one of his cases. *Absence of rigors* is a notable peculiarity. We have been accustomed to regard it as almost a necessity to have rigors or chills developed during the progress of purulent formations, but in all these cases which had fallen under his observation this symptom had not been present.

The doctor referred to the fact that he had seen several cases where swelling of the limb followed the development of an attack that was to terminate in the formation of a perityphlitic abscess, and the cases were mistaken for phlegmasia alba dolens. But the appearance of the limb is something entirely different when the swelling is developed as the result of the abscess, from that presented when the swelling is the result of phlebitis. For there is, in the case of abscess, an absence of the glistening skin, tenderness upon pressure, and the œdema so commonly present in the *alba dolens* after the first three or four days. To the practised eye the appearance of the limb in these two conditions is entirely distinct.

Some of Dr. Barker's cases died of peritonitis ex-

cited by the presence of the abscess; some from exhaustion incident to the profuse suppuration. In some cases perforation occurred into the bladder and bowel, and in one case an external opening formed. One case recovered without operative interference. A number of cases recovered after an external opening was made. In one case of perinephritic abscess which the doctor mentioned, when an opening was made, the kidney could be distinctly seen and felt, and recovery took place. One case was related in which the aspirator was used and about one ounce of pus withdrawn, the patient placed upon large doses of quinine with the view of arresting cell-production, and the patient recovered.

Dr. Barker inquired of Drs. Buck and Weber with reference to the occurrence of rigors in their cases.

In Dr. Buck's last case there was a slight shiver lasting only a few minutes in the earlier part of the attack; and in Dr. Weber's cases there was a rigor in the first, but not in the second and third until the succeeding troubles were developed.

Dr. Buck remarked regarding the occurrence of hernia, that in his first case a sufficient length of time had elapsed to determine whether the tendency existed or not, but that it was absent, and there seemed to be no special liability to its production.

He further enforced the proposition that the *circumscribed sensitive* point indicates the exact location of the abscess, and that elevation or redness of surface were not necessary to a diagnosis, nor should the presence of a tympanitic percussion-note over the tumor deter from the operation. The resonance can be explained by the development of gas in the cavity of the abscess, thus giving rise to tympanitic resonance where formerly dulness was present. The doctor also considered it important to avoid wounding the abdominal parietes to any greater extent than is absolutely necessary.

A small canula No. 1, bougie scale, can be introduced with perfect safety; for if it should penetrate the intestine no harm will follow.

He further alluded to the fact that it was Dr. Hancock, of London, who first performed the operation in the year 1848; and that Dr. Willard Parker revived it in 1867.

The question was raised by a member, Why not operate earlier and introduce the needle of the aspirator, say on the third or fourth day? What harm can be done? Would it not be justifiable?

Dr. Weber expressed the opinion that nothing is to be gained by interference before the tumor can be distinctly felt, at which time adhesions have probably taken place. He disapproved of any operative interference whatever before the sixth or seventh day; possibly in some cases by the fifth.

Dr. Buck corroborated the opinion of Dr. Weber regarding too early operative interference.

The Academy then adjourned.

Uterine Vaccination of a Lamb.—In 1851 a flock of ewes was vaccinated by Mr. Sylvain, V. S. Amongst them several were pregnant. On the twentieth day following the operation, a lamb born of one of the vaccinated ewes presented on the inside of the left thigh the three marks which had been made on the mother, at the same place and on the same leg, when the lamb was yet a fœtus. She had been delivered twelve days after vaccination, and on the twentieth day the pustules were in both, ewe and lamb, in the period of desquamation.—*Recueil de Médecine Vétérinaire.*

Correspondence.

"MILK OF MAGNESIA."

To the Editor of The Medical Record.

Sir:—There is a proprietary preparation with the above title for sale in the shops, which has given rise to considerable discussion. On the one hand, it is claimed on the label that it consists of "a simple mixture of pure hydrate of magnesia with pure water." On the other hand, those who have tried to mix hydrate of magnesia with water, without the intervention of gum, sugar, or other intermedium, have completely failed, and are ready to assert that the preparation is not what it purports to be.

Whatever may be the "new process" to which the proprietor lays claim, it is certain that a permanent "mixture of pure hydrate of magnesia with pure water" may be easily prepared by precipitating a solution of Epsom salt with caustic potash or soda, and removing the resulting sulphate by repeated washings, decanting the clear liquid in the upper part of the vessel each time, and adding a fresh quantity of water. The last decanting will leave a milky fluid, consisting of the loose flocculent precipitate of hydrate of magnesia, with just enough water to fill the interstices. The apparent *suspension* of the magnesia is owing to the loose and bulky character of the precipitate, as is shown by the fact that if the latter be collected on a filter, dried and reduced to powder, it will no longer mix with water, but will sink promptly to the bottom.

The fluid obtained as above described seems to be identical with the so-called "milk of magnesia," referred to above. It has exactly the appearance of milk, and when a very little sugar is added it resembles it closely in taste. This makes its administration extremely easy, while being in a liquid form it acts more promptly and uniformly than the powder, and we should suppose would be less likely to form concretions in the intestines.

It is an exceedingly useful and convenient preparation, and ought to be kept by every druggist in the place of the patent article, which is sold at an extortionate price.

Andrew H. Smith, M.D.

110 E. 38th St., New York, *Nov.* 24, 1875.

RECOVERIES FROM GUNSHOT WOUNDS.

To the Editor of The Medical Record.

Sir:—In the perusal of some of the late numbers of your journal, I have read with a deal of interest the history of a number of cases of remarkable recoveries from terrific wounds, and although not able to give you a case in which the anatomy had been as badly abused as described in at least one of your published instances, yet I am disposed to contribute my mite to the collection of remarkable recoveries from gunshot wounds.

Every one who participated (in either army) in what was called the "Banks Red River Expedition," during our late "unpleasantness," will remember the exceedingly rapid retreat which was made by that column; and also the fact that most of the Federal wounded, who were at all badly hurt, died either on the field of battle, or fell into the hands of the Confederates, and eventually died from lack of proper attention. The

history of the case that is about to be related is, therefore, more than ordinarily interesting, from the fact that the patient was in some manner carried along with the retreating troops, and recovered from his injuries, measurably at least, without any other hospital advantages or surgical attendance than a retreating army could give when it had been completely routed.

The description of the case is transcribed from an old pension docket, made while I was examining-surgeon for pensions at Lancaster, Ohio, in 1868 and 1869, and is taken from the last examination made by me, which was on September 1th, 1869, and was made in an exceedingly hurried and careless manner. I have not seen the veteran since, but it is fair to presume that he is still living, and engaged in the pursuit of his ante-bellum occupation, namely, that of a cobbler. In a visit paid to the vicinity of his former home, a few weeks ago, I made some inquiries as to his whereabouts, and was informed that, several years before, he had "gone west," and was, when last heard from, flourishing in that country, wherever it may be. I give the whole entry as it stands on the book, and perhaps the narrative may attract the attention of some one who has seen the subject since I have, and who may be able to add some important particulars thereto.

"Re-examined Sept. 4th, 1869.—John B. Goman, late a private in Co. A, 11th Regiment Iowa Volunteer Infantry, is inscribed upon the roll of the Columbus (Ohio) Agency. He was wounded at the battle of Pleasant Hill, Louisiana, during the Banks Red River Expedition, seven times, as follows:

"*1st.* Produced by a splinter driven from a tree by the bursting of a shell; struck the left side of the neck below the ear, and between the sterno-cleido mastoid swell and the ramus of the jaw. The results of this wound have been an immense cicatrix, total loss of hearing in the left ear, and partial anchylosis of the jaw.

"*2d.* Produced by a musket ball, which penetrated the left thigh at a point seven inches above the patella, on the inner margin of the rectus muscle, passed upward and outward, and emerged at the point where the sensor vaginæ femoris becomes tendinous, and beneath the vestus externus. The results of this injury are a large and constricted cicatrix.

"*3d.* Caused by a musket ball, which penetrated the left thigh over the belly of the rectus muscle, passed directly backward, and emerged at the upper angle of the popliteal space, fracturing and comminuting the shaft of the femur outrageously. The results of this wound are deeply depressed cicatrices, and a large callus at the point of union in the bone.

"*4th.* Caused by a musket ball, which entered the outer side of the left thigh, at a point over the origin of the vastus externus, passed downward, inward, and backward, and yet remains embedded and encapsuled beneath the inner condyle of the femur, and very near the knee-joint. The results of this wound are deep cicatrix, and partial anchylosis of the left knee-joint.

"*5th.* Caused by a musket ball, which penetrated the inner side of the left leg, at a point six inches above the internal malleolus, and over the inner edge of the tibia, and was extracted from the same place, having spent its force. The result of this injury is a very large and painful cicatrix.

"*6th.* Produced by a musket ball, which entered the left leg at a point one inch behind the point of entrance of the fifth wound, passed downward and outward, and now remains encapsuled in the interosseous space, and near the ankle-joint. The results of this wound are the usual cicatrix, partial anchylosis of the ankle-joint, and intense pain on movement.

"*7th.* Caused by a canister shot, which penetrated the posterior surface of the right thigh at the upper angle of the popliteal space, passed downward and outward, producing a compound fracture of the femur in its course, and emerged at the point of the commencement of the tendon of the long head of the biceps, about three inches above the external condyle of the femur. The results of this wound are a very large cicatrix, a considerable malformation from improper union of the fracture, and noticeable anchylosis of the knee-joint. He cannot walk except with great pain, and can do no work except in a sitting posture. The case has in no wise improved."

After this description, who shall say that the enemy did not obey the orders of their commanders to fire low? I have no doubt, judging from the evidence orally given by Goman, and the nature of his wounds, that it must have literally *rained* missiles during the battle of Pleasant Hill. I inquired of him as to whether at the time he was wounded, or at any time since then, he had been able to decide which one of his injuries brought him to the ground. He replied in substance: "I received *all* the wounds at the same instant, and went down all in a heap at once. I tell you it just *hailed* bullets there, and a fellow couldn't get away from them, either."

I am sorry to be unable to give a more detailed narrative of the case, but on the whole the case can be reasonably classed with the late one in THE RECORD, which was the subject of twelve wounds.

Very respectfully,

JOSEPH R. BECK, M.D.

15 EAST WASHINGTON ST., FORT WAYNE, INDIANA.

CHANGES IN THE PUBLIC SERVICE.

ARMY.

Official List of Changes of Stations and Duties of Officers of the Medical Department United States Army, from Dec. 19th to Dec. 24th, 1875.

BARNETT, R., Assistant Surgeon.—Assigned to temporary duty at Jackson Barracks, La. S. O. 232, c. s., Department of the Gulf.

COWDREY, S. G., Assistant Surgeon.—Assigned to duty at Jackson Barracks, La. S. O. 232, Department of the Gulf, Dec. 18, 1875.

TORNEY, G. H., Assistant Surgeon—Assigned to duty at Post of Pineville, La. S. O. 232, c. s., Gulf.

WASHINGTON, Dec. 23, 1875.

The following decision as to the status of Acting Assistant Surgeons in the army is announced: Acting Assistant Surgeons are entitled to the same protection in their positions, also to the same respectful subordinate conduct, and to the same military courtesy from enlisted men, as would be the case if they were commissioned officers. They are placed in the position of commissioned officers so far as relates to their duties as surgeons by the United States Government.

MR. ACTON, a London physician, who is known by his writings on the generative organs, prostitution, and allied subjects, died suddenly on the 7th of December of syncope, from fatty heart.

DR. G. B. OWENS, J. P., has been elected Lord Mayor of Dublin, Ireland.

Medical Items and News.

The "Mass Meeting" Resolutions.—Information Wanted.—"Citizen" sends us the following:—"*Dear Sir:* It will be remembered that at the 'mass meeting' (so-called) of the profession, held on Nov. 30th, that after the passage of the 'resolutions,' Dr. Gillette's motion, 'that the resolutions be printed and a copy be sent to the secretary of every hospital and dispensary in the city.' was adopted. Now, I ask for information why this resolution has not been carried out? I state, by authority, that the Governors of the New York Hospital are particularly desirous that the 'resolutions' should be laid before them at their next monthly meeting."

New York Academy of Medicine.—The following donations have been made to the library of the Academy since Nov. 24, 1875:

From Dr. Elisha Harris—A volume of the "Medical Papers of the U. S. Sanitary Commission Memoirs," edited by Prof. Austin Flint, M.D.; Vol. I. of Public Health Papers of the American Public Health Association; a filed series of the Weekly Statement of the Bureau of Vital Statistics of the City of New York.

From the Board of Health of New York—Fourth Annual Report of the Board of Health of the Health Department of the City of New York, May 1, 1873, to April 30, 1874.

From Dr. H. T. Banks—The American Dispensatory, edited by J. R. Coxe, M.D., 1823.

From Mr. I. F. Wood—Twenty miscellaneous pamphlets on medical subjects, and ten numbers of medical journals and reports.

From Trustees of the Johns Hopkins Hospital, Baltimore, Md.—One volume entitled "Hospital Construction and Organization," 1875.

From Dr. James R. Leaming—A volume on surgery, by Ambrose Paré, printed in Dutch in 1655, formerly owned by Dr. Gerardus Beekman, who was a prisoner of war in the American Revolution, and was released to do duty because of the small number of surgeons.

From E. D. Hudson, Jr.—The Materia Medica of Cullen, 2 vols., Edinburgh, 1789; Cours d'Anatomie Médicale, Portat, 5 vols., Paris, 1803; Anatomie Général, by Bichat, 4 vols., Paris, 1821; Œuvres Chirurgicales, by Dissault, 3 vols., Paris, 1813.

From Mr. Juan Cimeros—Medicine Legale, by J. L. Casper, 3 vols., Paris, 1862.

From Dr. Francisco Dichiara, Corresponding Fellow of the Academy—A Pamphlet on Electricity in Surgical Diseases.

From Dr. Sell—Physician and Pharmacist, Nov., 1875.

The following works by Dr. Austin Flint were presented by him:

Essay on Conservative Medicine and Kindred Subjects, 1874; A Practical Treatise on Physical Exploration of Chest, 1866; A Practical Treatise on Disease of the Heart, 1870; a Volume on Phthisis, 1875; A Treatise on the Principles and Practice of Medicine, 1873.

Dr. P. De Marmon, of King's Bridge, N. Y., is spending the winter at St. Augustine, Florida, on account of impaired health, consequent upon an attack of pneumonia last spring.

The Manual of Thermometry, by Dr. E. Seguin, of this city, has been translated into Italian by Dr. Alberto Zeri. This is another evidence of the appreciation of American labors abroad.

The Vivisection Question in England.—*The British Medical Journal* says that the Committee of the Association for the "Promotion of Human Treatment of Animals," have resorted to the plan of placing in the hands of young ladies, papers for the signatures of their friends, and remarks: "This Committee ought really to be congratulated upon their system of working, if it be carried out so completely in England as we have been informed has recently obtained in Lincolnshire, when it was suggested that the visitors attracted to the neighborhood by the festivities incidental to the race-week should be applied to for their signatures. How could there be a more perfect way of obtaining opinions on an important scientific question, than by sending to young ladies in country houses, papers for such a purpose? Happening to see one of these valuable documents, we observed that three-fourths of the names were those of ladies, one of whom, however wise in her generation, only gave her initials, as she thought that 'by so doing, her name would carry greater weight.' How charming in a ball-room for one of those enthusiastic young ladies to be able to make it a stipulation that, if she danced with him, he must sign her anti-vivisection paper?"

Dr. J. Murdock Harvey.—At a special meeting of the Medical Staff of the North-eastern Dispensary, held December 10th, 1875, a committee of three was appointed to draft resolutions regarding the death of the late Dr. J. Murdock Harvey, consisting of Drs. W. Schoonover, D. H. Mount, and E. H. M. Sell, who presented the following preamble and resolutions, which were unanimously adopted:

Whereas, The members of the Medical Staff of the North-eastern Dispensary having learned of the sudden demise of their esteemed brother and co-laborer, Dr. J. M. Harvey; therefore,

Resolved, That in the death of Dr. Harvey this medical staff has lost one of its best members, and a most zealous laborer in the cause of medical science. Self-sacrificing and generous to a fault, none knew him but to love him. He died a martyr to his profession, having contracted the disease which caused his death while administering to a charity patient in this Dispensary.

Resolved, That we cherish his memory as a noble example of professional integrity worthy of our emulation.

Resolved, That while we mourn his loss, we are assured that he is not dead, but sleepeth, and will one day awake to receive the reward of the righteous.

Resolved, That a copy of these resolutions be transmitted to the family of the deceased, as an expression of our sympathy in their great bereavement.

Resolved, That a copy of these resolutions be sent to The Medical Record.

W. Schoonover, M.D., *President.*
E. H. M. Sell, M.D., *Secretary.*

Small-pox in London.—According to the Registrar-General no death has been referred to small-pox in London for over four months.

Original Lecture.

THE INFLAMMATIONS AND THE CONGESTIONS OF THE NON-GRAVID UTERUS.

PRELIMINARY LECTURE

By E. R. PEASLEE, M.D., LL.D.,

PROF. OF GYNÆCOLOGY IN BELLEVUE HOSPITAL MEDICAL COLLEGE.

PART II.

GENTLEMEN:—The second cause of the unsatisfactory progress respecting the inflammations and the congestions of the uterus is—

The assumption that inflammation is the principal, if not the exclusively controlling, element in uterine pathology.

To a student of our science, the idea that uterine disease in general is produced by any single pathological condition, is simply absurd. Yet the following exclusive views have produced as many epochs in the history of gynæcology since I began to give special attention to this department of practice. From 1835 to 1845 Lisfranc, of the La Pitié Hospital (Paris), treated cervical ulceration as the only important uterine affection besides the malignant diseases. Dr. J. H. Bennett, in his work published in 1845, maintained that "ulcerative inflammation of the os and cervix uteri is the one great element in uterine pathology." Ten years later, Velpeau proposed the mechanical view of this subject, attributing these affections, inflammation even, to displacement of the uterus; and which has been revived by Dr. G. Hewitt in the last edition of his work. The surgical epoch, starting about 1864 with the notion that almost all uterine affections, and many others peculiar to women, demand surgical, and even operative interference, reached its acme by 1870, and fortunately is still declining. Dr. Chapman, in 1872, asserted in his work entitled "Hysterology," that congestion is the fundamental element in uterine pathology; a work of much merit notwithstanding its exclusiveness, but not duly appreciated by the profession at large, since most gynæcologists even, ignore the fact that the uterus is capable of becoming congested.

We find, in fact, as might be expected, that inflammation, displacement, congestion, tumors, carcinoma, and various other conditions may be the starting-point in uterine affections, and the history of each case must determine its originating element.

But the asserted exclusive agency of inflammation in uterine pathology has very naturally led to a third cause of the confusion I am illustrating, viz., *the mistaking another pathological condition for inflammation, and calling it such—which differs from inflammation in all its characteristics and effects.*

The condition thus misunderstood and mistaken for inflammation, proves on examination to be congestion alone; and it is important next to consider the

NATURE, VARIETIES, AND EFFECTS OF CONGESTION.

If inflammation be produced in the web of a frog's foot by the application of a stimulant, *e.g.*, the tincture of capsicum, the following order of changes occurs:

1. There is an increased rush of blood into and through the vessels of the part; *i.e.*, the activity of the circulation is increased.

2. The capillaries become abnormally distended by the blood, and thus partially lose their power of transmitting it. Now there is diminished circulation in the part, though too much blood.

The first of these conditions is active and the second is passive congestion. There is hyperæmia, or excess of blood in the vessels, in both.

3. The action of the stimulant being still further prolonged, a third change ensues, viz., the blood becomes stagnant in the over-distended and paralyzed vessels, and the liquor sanguinis exudes through the vascular walls into the inter-vascular spaces, and the vessels now contain the blood-corpuscles alone. In other words, as will be at once perceived, actual inflammation has now obtained.

I verified this statement thirty years ago, and recently J. Lister has also done so; and I reproduce it here to show the ready merging of either form of congestion into inflammation.

On the other hand, if the action of the stimulant be withdrawn, the reverse order of these changes now occurs: inflammation exhausting itself, to be followed by passive congestion; this by active congestion; and the last, in favorable cases, by the normal state of the circulation of the part. The stimulant action might also have been applied only long enough to produce active congestion, or that and subsequently passive congestion, and thus to have stopped short of the inflammatory process.

Congestion of either form, therefore, strongly predisposes to inflammation in a part; and the latter leaves the part for a time in a state of congestion, unless it ends promptly in resolution.

Congestion of both forms may end promptly (in resolution), or, unlike inflammation, may continue for an indefinite period. Any given case of either kind, not promptly disappearing, may therefore be recent or chronic. And the effects of chronic congestion, both active and passive, are next to be considered.

I. CHRONIC ACTIVE CONGESTION.—ITS EFFECTS.

Active congestion being merely an exaggeration of the normal circulation of a part,* will, if long continued, as might be supposed, produce an increased nutrition of the part; hypertrophy, as I have already explained it, being the common result of active congestion, if it become chronic. It also increases the natural secretion of a part (if a membrane), but without changing its quality. Meantime, it is liable at any moment to pass into passive congestion, and then into inflammation. It is not attended by fever.

I shall present to you no less than eleven distinct illustrations of hypertrophy in the uterus, produced by chronic active congestion, the nature and cause of these changes having hitherto been overlooked.

The hypertrophy from chronic active congestion may often be removed by appropriate treatment, but in some cases it must continue through life.

The redness of active congestion is rosy—a mere exaggeration of the natural color of the part—and readily disappears on pressure, to return at once. The eruption of a mild case of scarlatina is an illustration.

II. CHRONIC PASSIVE CONGESTION—ITS EFFECTS.

In specifying the effects of passive congestion, I need allude to its recent form only so far as to repeat its tendency to pass into inflammation. But two distinct forms of passive congestion must be mentioned in

* Active congestion is normal in the uterus and ovaries during ovulation and menstruation; but becomes pathological if it persists after the menstrual period ceases.

reference to its origin; viz., venous (or mechanical) and capillary passive congestion.

1. Venous congestion results from mechanical obstruction to the veins of the part. As illustrations, I mention congestion of the lungs from contraction of the mitral orifice of the heart; of the stomach and intestines from cirrhosis of the liver; and, as especially important to my main purpose, congestion of the uterus and ovaries from its various displacements, and from the pressure of intra- and extra-uterine tumors. In all such cases congestion commences in the veins, and extends secondarily to the capillaries of the part.

2. Of passive congestion, which commences in the capillaries, the following examples may be given: The general lividity on the surface of the body in cases of pulmonary emphysema—the highly carbonized blood directly paralyzing the capillaries; the blueness of cold hands; the redness of the nose, ears, or extremities of those whose circulation is languid from any cause. Hence, also, the hypostatic congestion in low fevers; and in the uterus, passive congestion is often produced by either of the two causes next to be mentioned.

The *immediate cause* of capillary passive congestion is probably a paralysis of the nervi-vasorum (Rokitansky), depending upon a debilitated state of the nerve-centres, or a pathological state of the blood acting more directly upon the vaso-motor nerves. The *predisposing causes*, all of them especially active in producing passive congestion of the uterus, are:

1. Local debility of the part, especially as ensuing after a previous inflammation.

2. General debility from any cause.

3. A diminished amount of fibrin in the blood (hypinosis).

The redness of capillary passive congestion is always of a dark, and sometimes livid tinge, returning slowly after pressure, as seen in the eruption of a case of asthenic scarlatina. There is no increase of temperature, and there is a sense of weight and dulness, rather than pain. There is no general hyperinosis, or subsequent induration, as in inflammation, and no subsequent hypertrophy, as after prolonged active congestion. There is no fever.

A. The effects of venous passive congestion are:—

1. Œdema from effusion into the connective tissue of the part, and dropsy of the serous cavities.

2. Extravasation on the capillary side of the obstruction; *e.g.*, hematemesis from cirrhosis of the liver, and hemorrhage from varicose veins.

3. Increase of secretion of the part (if a membrane), with change in quality.

4. A thrombus (coagulum) from the obstructed vein may enter the heart and lungs, or into the general circulation, and finally lodge in some part to constitute "embolism."

5. Gangrene may result, as from bandaging a limb too tightly.

6. Inflammation is common in parts easily disposed to it. As the uterus is naturally peculiarly indisposed to assume the inflammatory process, either form of passive congestion may exist, for many years even, in that organ without producing it.

B. The effects of capillary passive congestion are:—

1. Œdema of the part from effusion; dropsy of serous cavities.

2. Atrophy of the part, with some hardening, and more or less of degenerative change.

3. Increase of secretion, with change in quality.

4. Liability to active congestion, with recurring inflammation; in the uterus, especially to the former.

Finally, the general effects (the sequelæ) of inflammation, active congestion, and passive congestion, may be summarized as follows. The bearing of the preceding views on the inflammations and the congestions of the uterus will appear as I proceed to consider them.

INFLAMMATION AND CONGESTION.

		IMMEDIATE EFFECT.	SECONDARY CONSEQUENCES (SEQUELÆ).
Inflammation		Exudation producing Œdema. Fever.	Absorption (resolution). Adhesions; suppuration. Induration. Diminished and changed secretion.
Congestion	Chronic active.	Hyperæmia with slight œdema. No fever.	Hypertrophy and Hyperplasia. Increased but not changed secretion.
	Chronic Passive	Hyperæmia with effusion, producing pitting œdema. No fever.	Extravasation. Thrombosis and embolism. Dropsy. Increased and changed secretion. Atrophy and degeneration.

Original Communications.

PUERPERAL FEVER, WITH SPECIAL REGARD TO ITS NATURE, ETIOLOGY, AND TREATMENT.

By W. B. RODMAN, M.D.,

FRANKFORT, KY.

Being a paper read before the Transylvania Medical Society, at Shelbyville, Ky., Nov. 3, 1875.

I APPROACH the subject of this paper with great diffidence and distrust in my ability to bring order out of the chaos of opinions, which have been and are still held by the numerous authors and writers on puerperal fever. Probably more has been written, to less purpose and with less unity of opinion, on this than any other disease. This remark will certainly be verified by any one who studies the literature of the past and present on this subject. So varied and conflicting are the opinions of various authors, equal in eminence, that the more one reads, the more vague and confused his ideas become; until at last, in utter perplexity, he feels that he is unable to master even the nature of the disease in question. There has been more antagonism as regards the nature and etiology, than the symptoms, treatment and pathology, although the latter is exceedingly variable, and has been the subject of much discussion and difference of opinion.

I will not attempt to discuss puerperal fever thoroughly as regards the history, pathology, symptoms, diagnosis and prognosis, but will give to the nature, etiology and treatment (especially the prophylactic) such prominence as I think they deserve. My reasons for this will appear before this paper is concluded.

In the "Nomenclature of Diseases" drawn up by a committee appointed by the London College of Physicians, puerperal fever is defined as "a continued fever, communicable by contagion, occurring in connection with childbirth, and often associated with extensive local lesions, especially of the uterine system." To this definition this note is added: "In returning cases of puerperal fever, the more important local lesions, such as peritonitis, effusions into serous and synovial cavities, phlebitis and diffuse suppuration should be specified."

I believe that the only true classification of all specific or infectious diseases must be made with due regard to their etiology. This statement becomes the

more evident upon mature reflection. Classification from symptoms and pathology brings endless confusion in its train. If we were to decide the nature of a disease from the symptoms, an ordinary dysentery would become an epidemic dysentery, an ordinary cholera morbus would not differ, except in degree, from Asiatic cholera, nor diphtheritic laryngitis from membranous croup. If we relied on pathological changes, a malarial fever would be a splenitis, and epidemic cerebro-spinal meningitis would not differ from an ordinary meningitis. Take for instance this illustration, which seems pertinent to the present subject. A patient is taken violently ill, with symptoms of severe systemic poisoning from some acute infectious disease. Death may occur in twenty-four or thirty-six hours. There may be no characteristic symptoms, and the most careful autopsy reveal no pathological changes by which we are able to characterize the nature of the disease. It may be said that this is an extreme case. Still, cases have occurred, especially in puerperal women, termed by the French "foudroyant," that is, thunder striking, crushing, which fully sustain the illustration. Here we would be at a loss to know with what particular poison we had to contend, but by tracing the history of the case to its *cause*, we may find that our patient has come in contact with scarlatina, variola, erysipelas, or has been infected with a large quantity of septic poison, which has produced death so rapidly, that no characteristic symptoms or pathological changes have had time to develop. Other illustrations could be given, but these are enough to prove that symptoms and pathology neither separately nor combined are sufficient for a correct and satisfactory classification, especially in specific or infectious diseases. On the other hand, reasoning from cause, a slight varioloid is essentially the same as a malignant variola: the mildest scarlatina, which is scarcely noticeable, is identical in its nature with malignant scarlatina, which may carry off the patient in twenty-four hours. "The cause the same, the nature of the disease the same," is an axiom worthy of adoption in the discussion of specific diseases.

When we have discussed the etiology of puerperal fever we will see that the term is unfortunate, that really there is no such disease sui generis, but that various authors have given the name to diseases which are as distinct in their essential qualities as erysipelas, variola, scarlatina, septicæmia and pyæmia. As Liebermeister justly remarks, the nature of puerperal fever can never be properly understood until the causes are defined.

Let us now see what the most probable causes of puerperal fever are, sifting carefully the mass of evidence before us; and it would be proper, as Mr. Spencer Wells suggests, to discard all theories which are not in some measure supported by facts. Many physicians who have written on or discussed puerperal fever are agreed, that some of the most violent attacks have been undoubtedly due to contact, mediate or immediate, with cases of scarlatina. It is unnecessary to mention all those who have expressed this opinion, and it will be amply sufficient to refer to a few, who have sustained their theories with facts, which seem to me indisputable. Dr. Braxton Hicks mentions a series of eighty-nine cases of puerperal fever; of these, thirty-seven were clearly traced to scarlatina; twenty had the rash, seventeen had not. I will venture to report the history of two of these. A woman was taken with the most violent form of puerperal fever, and died about the third day. There was no previous history of scarlatina, but in a few days two of her children had malignant scarlet fever, and died. A lady had been delivered twelve hours when feverish symptoms set in; a pile already inflamed became very tender and painful; from this part a blush spread, something like erythema, but without any defined edges, and extended over her back. About the third day arthritic pains and swelling commenced, with delirium. These symptoms increased in intensity, and she died in great agony on the fifth day. No *exanthematous* exposure could be discovered; in a week, however, two of her children died with scarlatina, and the infant barely escaped with its life.

Trousseau mentions an endemic of scarlatina occurring in a village in France, which proved so fearfully fatal to puerperal women, that even the poorest were compelled to leave the place when they were confined, to escape almost certain death.

I cannot offer a better illustration of the power of erysipelas to cause puerperal fever, than by relating a series of circumstances which occurred in Frankfort last winter, and which I have previously reported in THE NEW YORK MEDICAL RECORD for Aug. 14th, 1875. Dr. —— attended a case of facial erysipelas from the 9th to 22d December, 1874. During this time (Dec. 14th) he delivered Mrs. P. of a child at full term. On the 15th she had a low form of fever (puerperal?), with some peritonitis, and died on the 17th. On Jan. 13th, 1875, he delivered Sally W., colored. On the 15th she had the same fever, with similar symptoms, and died on the 16th. January 14th, he examined the womb of non-puerperal Mrs. W. He found it prolapsed, and with two recent abrasions on the os. On the 15th she had fever and symptoms resembling those of the two puerperal women, and died on the 17th. January 10th, Dr. —— examined the womb of Louisa (colored). On her uterus there were abrasions. She had the same fever, beginning on the 13th, and died on the 19th. No other physician in Frankfort or vicinity had any cases of this kind. As no autopsies were made, I cannot say what pathological lesions existed. I saw, in consultation, one of these cases (white), and there was no appearance of erysipelas externally, but I firmly believe that these women all died of that disease.

It has been suggested that it is to country doctors, or those practising in the smaller towns and villages, that we must look for *facts* which will enable us to arrive at a proper understanding of the nature of the causes of puerperal fever. This is obvious for the following reasons: It is next to impossible for those living in large cities, or practising in hospitals, to exclude various *factors* which may abound. Given a case or cases of puerperal fever, occurring in a large city or a hospital, we cannot say with any degree of certainty whether the patient is infected by some of the exanthemata (which are almost always present), or whether the infection is due to pyæmia or septicæmia, which is often present in hospitals, or whether it is due to autogenetic poisons, that is to say, poisons which may originally and exclusively develop in the body of the patient herself. Suppose, again, that a practitioner should have reason to believe that he had been the medium of contagion through his clothes or person. He might, if engaged in a large city practice, or in hospital attendance, have seen, recently, cases of scarlet fever, erysipelas, etc., or have been engaged in dressing a septicæmic wound, or in making a post mortem examination. Here, naturally, he is at a loss to say which of these possible factors is the true one. Not so with the country doctor. Possibly for weeks he has seen not a single case of any contagious disease, has dressed no wounds, has made no autopsies. The cause is here narrowed within certain limits, and is the more easily and certainly ascertained. For these reasons I contend that such facts as

I have mentioned above, as coming under my own observation, are valuable in the highest degree, for in these every possible factor can be excluded except erysipelas. Trousseau, who gloried more in facts than theories, and who was one of the closest of observers, relates that during an endemic of puerperal fever in the Hôtel Dieu, most of the children born of these puerperal women died of a malignant erysipelas, which was so rapid in its course as to leave no appreciable internal lesions. If we can believe that these puerperal women had a disease, which produced erysipelas in the children, we know that their disease was erysipelas, although the characteristic symptoms and lesions were absent. We know for truth that variola, scarlatina, and erysipelas beget, respectively, variola, scarlatina, and erysipelas. When a mare foals a mule, we know that she has been bred to jack and not to a horse. When we see erysipelas in the child, produced by puerperal fever in the mother, we know that her disease is erysipelas, call it what you will.*

Dr. Parry, of Philadelphia, in a paper published in the *American Journal of Medical Sciences*, January, 1875, has fully shown that diphtheria may be a fruitful cause of puerperal fever. He mentions a series of cases which would be called puerperal fever, where the peculiar deposit existed in the genital organs. Prof. Martin, of Berlin, believes that all cases of puerperal fever are diphtheritic in their nature; but this is an extreme view which he alone endorses.

It is unnecessary to produce here facts to prove that other acute infectious diseases—as typhus, measles, small-pox, etc.—can also produce a fever which may be called puerperal. It is reasonable to suppose that if one infectious disease can produce it, another can; but that scarlatina and erysipelas are more prone to cause outbreaks of puerperal fever than the others seems probable. Even Prof. Barker, who contends that puerperal fever is a disease sui generis, and has distinct entity, acknowledges that the exanthemata can produce, in puerperal women, a fever strongly resembling that which is called puerperal. Might he not go farther, and say that the exanthemata will produce, in the puerperal woman, a disease which the great mass of the profession will unhesitatingly designate puerperal fever?

This much to prove the part that the infectious diseases play in the etiology of puerperal fever. It has been urged as an argument against this view, that in many of the cases of puerperal fever, there are not the characteristics of the disease which is supposed to have been the cause. I answer that the puerperal condition may so modify the disease as to make the recognition difficult; or that death may take place so rapidly that there is not time for the development of characteristic symptoms or lesions. Again, it has been said that puerperal women have been exposed to the exanthemata, and have had no puerperal fever. This proves nothing. It is not every one who is exposed that falls a victim to the poison. If it can be definitely proven that a dozen women have had puerperal fever caused by exposure to an exanthem, the fact of a hundred having escaped under similar exposure cannot disprove it.

While there are many who believe in the power of other infectious diseases to cause puerperal fever, some of them do not deny that pyæmia and septicæmia have also their importance. On the other hand, many eminent authorities, as Spencer Wells, Leishman, Barnes, Graily Hewitt, D'Espine, Billroth, and the mass of the profession in Germany believe that most of the cases of puerperal fever are purely septicæmic or pyæmic in their nature.

Billroth defines septicæmia as a "constitutional, generally acute disease, which is due to the absorption of various putrid substances into the blood, and it is thought that these act as ferments in the blood, and spoil it so that it cannot fulfil its physiological functions." It is believed that the septic poison is absorbed by the lymphatics alone, and that these vessels can only absorb it when there is a wounded or abraded surface, and not even then, provided there is an abundance of healthy granulations. Septicæmia may be either heterogenetic, that is, the poison is introduced from without, or autogenetic, where the poison is developed originally and exclusively in the body of the patient herself, and where outside influences have nothing at all to do with the infection. When we reflect on the condition of the puerperal woman, remembering the condition of the genital organs, the placental wound, the abrasions of the cervix and os uteri, and laceration of the perineum, the wonder is, not that so many women have septicæmia, but that so many have escaped the danger from within and without. The important fact to be remembered here is, the protective power of the granulations, for generally before septic poison can be developed (especially the autogenetic), granulations have covered the wounds and abrasions, and thus an impermeable barrier is set up to the entrance of the poison. Anything, then, which interferes with the granulating process, or which disturbs the granulations after they have formed, is bound to predispose the patient to septicæmic infection. It is evident that many diseases, by retarding the development of granulations, may cause septicæmia, as well as handling the parts in surgical operations after delivery. The sources of autoinfection are blood clots retained in the uterus and vagina, retention of parts of placenta or membranes, cloths in the uterine sinuses, and possibly thrombosis. If we conclude that the last may cause septicæmia from disintegration of the clot, traumatism is not a necessary precedent, for here the poison is already in the blood; but it is an exception to a very general rule for septicæmia to develop, except from a wound or abrasion. If it could be proven that septic or pyæmic miasms could be absorbed into the lungs, in the form of fungi or molecular bodies, it would revolutionize present theories. The sources of hetero infection are numerous. The attending physician may have about him the poison of a post-mortem examination, or of a septicæmic or pyæmic wound, or dissection of the dead body; and especially is he apt to communicate the disease if he has handled the putrid discharges of other puerperal women, or cloths which contain them. Some strong proof has been brought forward where a sore on the hand, which was in itself not poisonous, has been the source of infection. Not only, however, from the clothing and person of the attending physician, midwife, or nurse can the infection arise, but the poison may be in the air, especially of hospitals or crowded tenements, or any place where there is an aggregation of sick or wounded.

We all know the great danger to which patients with wounds are subjected in closely crowded hospitals, let the cause be what it will. Pyæmia is apt to become endemic, and count its many victims, especially should one case occur within the wards. So, in a hospital for lying-in women, is pyæmia apt to become a scourge. Pyæmia is defined as "a disease due to purulent infection, in other words, to the presence in the blood of pus or certain of its constituents." The old theory that pus, as such, could not enter the blood, has been proven fallacious by recent pathological researches, but

* I am aware of the fact that the etiology of erysipelas is not so definitely agreed on as that of the other exanthemata. Still I have given the view that is generally entertained.

it is principally to the liquid part of pus that pyæmia is due; the pus globule or leucocyte being innocuous. It is certainly unnecessary for me at this time to go deeper into the etiology of pyæmia than to say, that it is due to the absorption of pus, which may be influenced by the condition of the patient and his surroundings, and to discuss those surroundings. This brings us to the question "What relations have bacteria and allied organic forms to the pyæmic process in the puerperal state?" This is a difficult question to answer, as the study of these bodies is yet in its infancy. We know as yet comparatively nothing concerning them. Some eminent authorities contend that they are more the effect than cause of infection. Dr. B. W. Richardson believes they are merely coincident with disease; others again believe that they are the medium of contagion in certain instances. I believe no one at the present day denies the existence of bacteria, but what influence they exert is still involved in obscurity. They seem to exist everywhere, and if this be so, it is almost proof positive that they are in themselves innocuous. Prof. Lebert's theory is that each infectious disease, as the exanthems, typhoid, typhus, and relapsing fevers, etc., has its own peculiar protomycete or organic germ, which is in itself capable of generating these diseases respectively. But suppose they exist in hospitals or sick-rooms in great abundance, as has been demonstrated by Pasteur, Chalcot, Reveil, and others, is it not more likely that they may absorb the various poisons from infectious diseases, poisoned wounds, etc., than by coming in contact with a healthy person or a healthy wound produce the disease the poison of which they have absorbed? Can we not with propriety liken them to emigrants? Healthy emigrants coming into port will not cause disease of any kind, but let them be saturated with a specific poison, and the great probability is that diseases, specific in their nature, will ensue to those with whom they come in contact. If this theory be true, we can understand the prevalence of septicæmia and pyæmia in the wards of hospitals, and especially in hospitals for lying-in women. Billroth says that he has never seen an instance of this pyæmic or septicæmic miasm infecting the body except through a wound or lesion, though he does not deny the *possibility* of infection through the lungs. Pyæmia and septicæmia, then, may be contagious in a restricted sense of the word, and if so, it is easy to see that they may be fruitful sources of some forms of puerperal fever.

I believe that from the infectious diseases septicæmia and pyæmia arise all the cases which can be properly classed as puerperal fever. Since it is regarded as a disease communicable by contagion, it is useless here to discuss those cases of fever in the puerperal woman which are purely local in their nature, as non specific metritis peritonitis, etc. These diseases do certainly occur in the puerperal woman, and are accompanied by high fever, but no one will pretend to say that they are contagious. The condition of the puerperal woman, both mentally and physically, has been supposed to increase their liability to puerperal fever, even independently of any specific poison. Woman during pregnancy is peculiarly exempt from various morbific influences, but as soon as she is delivered she becomes, on the contrary, more than ordinarily susceptible of disease; but this could not produce scarlatina, erysipelas, heterogenetic septicæmia and pyæmia, unless other causes were present, and these causes must be the specific poison of the disease contracted. One reason that woman recently delivered is more prone to take a specific disease than at any other time, is the very rapid action of the uterine absorbent in the first two or three days after delivery. It is true that a woman will usually escape puerperal fever in certain of its forms, if she safely passes the first four or five days after delivery.

During the discussion of puerperal fever recently held at a series of meetings of the London Obstetrical Society, Mr. Spencer Wells propounded the following questions, so that the arguments of the different gentlemen might take a definite course:

1st. "Is there any form of continued fever communicable by contagion or infection, and occurring in connection with childbirth, which is distinctly caused by a special morbid poison, and as definite in its progress, and the local lesions with it, as typhoid, typhus, scarlet fever, small-pox, or measles?" To this I answer, No. The affirmative of this proposition cannot be proven until we find a contagious puerperal fever which has not arisen from some infectious disease, or is not septicæmic or pyæmic in its nature, and which will not, in its turn, produce a disease which we can recognize as a certain infectious disease, or a pyæmia or septicæmia. This is the view entertained by every physician participating in the discussion except Prof. Barker, of New York.

2d. "May all forms of puerperal fever be referred to attacks of some infective continued fever as scarlet fever or measles, occurring in connection with childbirth on the one hand, or on the other to some form of surgical fever, or to erysipelas caused by or associated with changes in the uterus and neighboring parts, following the process of childbirth?" This question was answered in the affirmative by the great majority, some few regarding fever from any cause in the puerperal woman as puerperal fever.

3d. "If all cases of contagious or infectious diseases which occur under other conditions than that of childbirth are set aside, does there remain any such disease as puerperal fever?" I think not; at least it remains to be proven. Leaving out Spencer Wells's 4th, we come to the 5th. "What relation have bacteria and allied organic forms to the pyæmic process in the puerperal state?" This question I have already discussed.

If the opinions advanced in this paper are correct, the pathology is necessarily very variable, and will resemble that of the various diseases which cause puerperal fever, except in so far as the lesions may be modified or influenced by the puerperal state. It is unnecessary for me to recapitulate here the pathology of the various infectious diseases, pyæmia and septicæmia. We would naturally suppose, that the womb and surrounding parts are principally affected, as it is through these the poison in most cases infects the system. It must be remembered that death may occur so rapidly, from an overwhelming poisoning of the entire system, that no important lesions may be discovered.

The symptoms occur in the first few days after labor, especially in endemic or epidemic puerperal fever, and generally within the third day. The reason for this I have already mentioned. In autogenetic septicæmia or pyæmia they may come on later. Like the pathological changes, the symptoms will vary according to the cause, though we may say with tolerable certainty that they are generally decidedly asthenic.

The diagnosis and prognosis it is unnecessary to discuss, as they depend also on the nature of the cause.

Treatment.—Spencer Wells's fourth question is, "Assuming that a form of continued fever, communicable by contagion, inoculation, or infection, does frequently occur in connection with childbirth, how can its spread in private and hospital practice be most certainly prevented or checked?" This is practically the most important part of the whole subject. When we

take into consideration the infectious and contagious nature of puerperal fever, and the different sources from which this infection and contagion may arise, we are surprised that the disease is not more generally prevalent than it is. In a hospital for lying-in women (which should be a distinct building, and not some particular ward of a general hospital) the utmost care should be taken that no infectious disease be admitted; and should a specific disease arise within, it should be at once isolated, and that completely. The utmost regard for cleanliness should prevail, and all soiled cloths, bed-clothes and clothing should be boiled and thoroughly disinfected as soon as possible. No physician should be allowed to attend any woman, without the greatest care had been taken, that he, his clothing and instruments, were perfectly free from all morbific poisons which might originate puerperal fever. Even these precautions will not protect patients in a lying-in hospital from nosocomial malaria, from bacteria, from those organic germs which only too frequently abound in the wards of hospitals. Probably the best plan to disinfect a room or ward of these germs or ferments would be the sublimation of sulphur, which produces sulphurous acid, a substance we well know to destroy the process of fermentation * Dr. Wynn Williams, of England, has recommended for a similar purpose iodine. A few scales of iodine placed on a hot metal plate are sufficient to disinfect the clothing and person of the physician, so that he may attend a lying-in woman with impunity. Special attention should be paid to the hands and nails. The history of puerperal fever abounds with instances where this dread disease has followed a certain physician until "his path became a highway of sepulchres." Undoubtedly he had communicated the disease by inoculation or contagion, the poison clinging to his person. Most of these cases, however, occurred before the days of disinfectants. Soap and water *will not* remove the poison from the hands. This fact I know from personal experience and observation I believe, however, that should a physician have the poison on his hand, and should wash them thoroughly with a solution of permanganate of potash, chloride of lime or zinc, chlorinated soda or carbolic acid, and apply a carbolated oil to his finger when making the necessary examination, he will certainly rid himself of the poison, and may attend cases of midwifery without danger to his patient. I believe it is Dr. Graily Hewitt who says that "a *nail-brush* is one of the most important instruments in the accoucheur's outfit." We all know that a physician has often and over again attended scarlet fever, erysipelas, dressed old wounds, and without taking any special precautions has attended lying-in women with perfect safety. It does not follow that there will not be instances when he will have good reason to regret that he had not disinfected his person and clothing. Ninety-nine times he may have no trouble, but the hundredth may bring disaster in its train that he can never forget or his patrons forgive. Provided a physician has had a case of puerperal fever in his practice should he abstain from midwifery practice for a certain length of time? If he changes every article of clothing and thoroughly disinfects his person, paying special attention to his hands and nails, I think that he may safely continue. But if, in spite of these precautions, a second case should occur, he owes it to humanity to give up at once all his obstetrical engagements for at least a month. The case of Dr. Rutter, of Philadelphia, is certainly a remarkable one. In spite of frequent ablutions and self quarantine, puerperal fever followed him until he left Philadelphia. I have recently seen it stated that Dr. Rutter had a chronic eruption of the skin, attended by a purulent discharge, which in itself might have produced puerperal fever in spite of all precautions which he took. Mr. Huntley, of Jarrow-on-Tyne, England, shows by a series of conclusive arguments, that "a secretion from his own hands was the cause, three times successively, after intervals of several months' practice, of conveying poisonous matter to patients, and so inducing puerperal fever." These facts should convince us all that a physician cannot be too careful when he attends a case of labor. The nature of the disease, and the great mortality which frequently attends it, must convince us that it is principally the prophylactic treatment which will avail us much in puerperal fever.

The treatment of a case of puerperal fever, when once initiated, must vary according to the cause. In other words, we must treat erysipelas, scarlatina, pyæmia, and septicæmia in the puerperal woman as we would in a non-puerperal person, with due regard to the modifications induced by the puerperal state. As in nearly all cases there is a decided tendency to asthenia, depleting remedies are out of the question. Quinine and tincture of the chloride of iron are the two constitutional remedies on which I would place most reliance. Opium should be given freely if there is much pain from peritonitis, metritis, etc. The local treatment should be the application of hot cloths or turpentine stupes to the abdomen. Blisters are hardly admissible. There is one point especially deserving of attention. In nearly all these cases there is excessive foulness of the lochia, amounting in some instances to putrefaction. Here antiseptic and disinfectant injections are of the greatest benefit. Numerous instances are on record where the most violent symptoms of puerperal fever have subsided like magic after intra-uterine injections of some disinfectant. For this purpose solutions of carbolic acid, permanganate of potash or chlorinated soda, and probably salicylic acid, will answer. The patient should be sustained by the most liberal diet and the use of stimulants. The use of the sulphites internally, as recommended by Prof. Polli, of Milan, has been tried, but the success has not been as satisfactory as we would expect from the theory. Spencer Wells's 6th and last question, "What is the value of antiseptics in the prevention and treatment of puerperal fever?" received but little attention in the recent discussion before the London Obstetrical Society. I have tried to briefly answer it when speaking of the treatment, both prophylactic and symptomatic. Most of the time in the recent discussion was consumed in the consideration of the nature and etiology of puerperal fever. It was remarked (I think in a review of the discussion) that by collating facts principally from physicians like ourselves, having what may be called a country practice, and by bringing pathology in all its bearings to our assistance, in *ten years* the profession might be able to say exactly what puerperal fever is, to define it as clearly as we can small-pox, typhoid fever, etc.

To us, then, gentlemen, falls the task of keeping an accurate record of every case of puerperal fever which may come under our own observation, using our best endeavors to trace every case to its source, if possible. Unfortunate and disagreeable as it might be for any of us to believe that we had been the medium of contagion, and probably the cause of death itself, still, let us imitate the example of those noble members of the profession who have confessed their misfortunes, I cannot say faults. By so doing we may warn our

* See remarks of Prof. Barker, in Oct. 30 No. MEDICAL RECORD, with regard to chlorine gas for same purpose.

medical brethren, and enable them to shun that which may prove humiliating to themselves and calamitous to their patients. If I can persuade you all, or any one of you, that this is the proper course to pursue, I will feel that this paper has not been written in vain.

A CASE OF URETHRO RECTAL FISTULA PRODUCED BY THE FORCIBLE INTRODUCTION OF SOUNDS.

RECOVERY AFTER PERINEAL SECTION AND RECTAL SUTURE.

By EDWARD FRANKEL, M.D.,

VISITING PHYSICIAN TO CHARITY HOSPITAL, ETC.

THE establishment of a fistula between the urethra and rectum has most often followed the penetration of catheters or sounds through the membranous portion of the urethra into the convexity of the last curve of the rectum, or into the portion surrounded by the sphincters. Only slight if any reference is made to this condition and its treatment in text-books on surgery, and but few cases are to be found in surgical literature. For this reason the following case is placed on record:

S. R., aged 40 years, born in Germany, merchant, married, consulted me last May for treatment of urethral stricture and cystitis. He stated that aside from his venereal trouble his general health had always been good. About fifteen years ago he contracted a gonorrhœa, which was neglected, and gradually subsided into a gleety discharge; about twelve years ago symptoms of stricture developed, for which he was treated by dilatation by various physicians. For ten years he has been in the habit of passing a No. 10 Engl. sound on himself at irregular intervals. About one year ago the stricture became very narrow, and cystitis developed, and he placed himself under the care of a physician, who used to pass a No. 12 Engl. sound, and injected the bladder. Much force was used at each introduction, and the patient suffered much pain, and lost blood. The cystitis and trouble in making water became very much aggravated, and about four weeks before I saw him he consulted another physician, who used great force in entering the bladder with a No. 11 sound; he suffered intense pain, and afterwards passed a large quantity of blood by the urethra. The sound was passed three times at intervals of three days, and the patient, instead of improving, found himself rapidly getting worse. In addition, he now noticed that he frequently passed wind by the urethra, and urine at each micturition by the bowel.

I first saw the patient on May 17th, 1875, and found him in a very nervous and feverish condition. He had had no sleep for several nights on account of having to pass water about every half hour, and micturition was accompanied by severe pain in the perineum, which radiated towards the back and right hip. The meatus allowed the passage of a No. 12 Engl. sound, which encountered an obstruction about half an inch in front of the bulbous portion of the urethra. This was easily overcome by a No. 10 conical sound, but a further obstruction was met with at about the membranous portion. All attempts to pass this stricture by various instruments failed, the instruments showing a tendency to deviate toward the right, and there was evidently a false passage in this location. While the patient passed urine in a very small forked stream, it was discovered that a considerable portion of it came away through the anus. Rectal exploration with the finger revealed a round depression, which felt like ulceration, immediately in front of the prostate, and about three-quarters of an inch in diameter. A No. 9 sound introduced into the urethra could be made to pass from about the membranous portion to the right into a false passage which led into the rectum. The patient was ordered warm hip-baths, poultices to the hypogastrium and perineum, and opiates. Bowels had moved freely. The urine contained much pus; no casts were discovered.

On May 18th, in consultation with Dr. Erskine Mason, it was decided to perform perineal section. The patient being etherized the meatus was incised, a sound introduced and external urethrotomy was performed in the usual manner. No trouble was experienced in the division of the posterior stricture. The neck of the bladder was well dilated with the finger, and a large amount of pus and stale urine was discharged. It was ascertained that the complication of urethro-rectal fistula had been caused by forcible sounding and the establishment of a false passage. The patient rallied well from the operation; he slept well and regained his appetite. All symptoms of cystitis had disappeared, which proved the advantage of the thorough dilatation of the neck of the bladder, by which free vent was given to the discharge of urine. Received quinine and tincture of iron. Passed four stools in the two days following the operation by the natural passage, but much flatus escaped by the perineal wound. During the four days preceding May 28th, he had no passage from his bowels, in consequence of which he had considerable headache and some fever, which condition was relieved by an enema of soap-suds and oil. On May 30th, a No. 16 Engl. sound was passed into the bladder by the aid of the finger in the rectum. The false passage was in close proximity to the urethra, and the latter could be felt as a thin wall between the sound and the finger.

Up to June 25th the patient had improved daily, and the perineal wound had undergone considerable contraction. On that date, being very constipated and feeling the necessity for evacuation, he took nearly two bottles of citrate of magnesia contrary to orders, with the result that nearly half of the fecal discharge came through the perineal wound. Severe constitutional disturbance followed, and the wound was with difficulty kept clean by means of injections and perineal douches of cold water. Quinine and opium.—On June 28th, by means of a Ferguson's rectal speculum, the rectal opening of the fistula, around which considerable ulceration had taken place, was discovered to be situated about 1½ inches from the anus. By means of Sims's probe, bent at a right angle for about an inch from its extremity and coated with nitrate of silver, the fistula was cauterized once every five days.

By July 10th feces ceased to pass by the wound, though wind passed frequently. By July 16th the perineal wound had contracted considerably, and the patient then was taken into the country, where he regained strength so rapidly, that after one week's sojourn he was able to walk out and take sea-baths. The passage of the sound once a week was continued.

On August 26th the wound had almost entirely closed, and could only be detected by stretching the perineum. Only a few drops escaped through it during micturition, though the patient was much annoyed by the passage of flatus through it. Rectal examination on September 8th revealed that the fistula had very much diminished in size, and now appeared as a valvular opening, with soft and granular edges; it measured about half an inch transversely. Cauteri-

zations were continued as before, and cold sitz-baths and perineal douches were continued at home.

Towards the middle of October the fistula had not closed and flatus continued to pass, sometimes by the meatus and sometimes by the small aperture in the perineum. I decided upon closing the fistula by means of sutures; and on October 20th, the patient being etherized, was placed on his left side, the sphincter ani was first thoroughly stretched by the thumbs, and then a two-bladed rectal speculum was introduced. A No. 16 sound was passed into the bladder so as to render the fistula more prominent in the rectum. By means of a curved pair of scissors, such as are used in the operation of staphylorraphy, the blades being bent at right angles to the handle, the edges of the fistula, which were raised as much as possible by a Sims's tenaculum, were freshened, and then three fine silver wire sutures were introduced, according to the method of operating for vesico-vaginal fistulæ. The patient received opiates to cause constipation. The operation was not followed by either fever or pain, he slept well, and there was no disagreeable sensation in either the rectum or bladder

The patient remained in bed up to October 26th, when he was placed on his knees and elbows, and the sutures were removed. The opening was found to have been united by the central suture and the suture to the left, while the angle to the right of the fistula had not closed, but the opening which remained was so small that no further trouble was anticipated. A copious evacuation, after a large dose of castor-oil, did not cause pain or re-establishment of the fistula, and at the present date, December 12th, the patient considers himself cured. The cold sitz-baths, however, as also the weekly passage of a No. 16 sound, are continued.

Progress of Medical Science.

Puncture of the Pericardium.—The following case is reported in the *Archives Médicales belges* by Dr. Villeneuve: A child, five years old, was suffering from pericarditis with effusion. According to the statements of the parents, the trouble dated from a fall two months before, soon after which the breathing began to be affected, the legs swelled, and the condition grew gradually worse. When the patient was seen by V. the symptoms had become very alarming. The face was swollen and mottled, the eyelids were œdematous, the lips cold and livid. There was also considerable œdema of the legs and scrotum. The pulse was too feeble to be counted, and auscultation failed to discover any cardiac sounds whatever. A fluctuating swelling, which undulated synchronously with the respiration, occupied the precordial region. Respiration was short, labored, whistling, and accompanied with pulsation of the jugulars. The case appeared desperate, and no medical treatment offering any prospect of success, it was resolved to interfere surgically. A Dieulafoy's aspirator was procured, and the tumor having been punctured at its most prominent part, two syringefuls of clear, yellowish fluid were withdrawn. The fluid continued to flow in a stream after the canula was removed, owing to the fact that the repeated application of blisters to the part had so thinned the skin as to prevent the edges of the wound from closing. With the aid of plasters, compresses and bandages, however, the aperture was finally closed. The result of the operation was a very marked relief of the child's asphyxiated condition; the heart-sounds could be heard again, and the pulse could be counted. The wound continued open and discharging for six months. The discharge was at first clear, and afterwards became purulent. The fistula finally healed, and the patient made a complete recovery.—*Journal de Médecine*, Aug., 1875.

The Value of Hysterotomy in the Treatment of Fibrous Tumors of the Uterus.—In a carefully considered monograph on the above subject by M. Samuel Pozzi, the following conclusions are stated:

1. Abdominal hysterotomy, in the treatment of fibrous bodies of the uterus, in an operation which although a very grave one, is in certain cases perfectly justifiable; it is fully entitled to a definite position in surgery.

2. No comparison, however, can be established between the indications for gastrotomy for uterine fibroids and those for the same operation in the case of cysts of the ovary.

Whilst the greater proportion of the latter demand or justify the operations by reason of their rapid and fatal course, the vast majority of the fibrous bodies of the uterus lack the indications which should be regarded as sufficient.

3. The operation should be reserved for the fibrous or fibro-cystic tumors, whose evolution is rapid, *galopante*, and are accompanied by grave symptoms that threaten life.

4. Large fibrous bodies which do not come within the above category, even though they give rise to serious accidents, should be treated by less dangerous methods. We know, in fact, that these tumors tend to grow smaller; that they are tolerated for considerable periods; and, in any case, it appears to be demonstrated by experience that the mortality resulting from the expectant treatment is far less than that which follows the operation of hysterotomy.

5. Whenever gastrotomy has been performed through an error in diagnosis, and a uterine tumor is found instead of an ovarian cyst, it is better to practise ablation, rather than to leave the operation incomplete, even though the fibrous body should not be pedunculated.—*Thèse d'agrégation*, par M. S. Pozzi.—Paris, G. Masson, libraire.

Resection of the Sternum.—Professor Costanzo Mezzoni reports, in the *Bulletin général de thérapeutique*, five cases of resection of the sternum, together with adjacent portions of the ribs and costal cartilages. In the first case the operation was performed on account of a large tumor situated in the middle of the sternum. The tumor was adherent to the bone, was painless, hard, and at certain points presented a sense of fluctuation, but further than this its nature is not stated. The sternum was removed entire, together with portions of the costal cartilages of the second, third, and fourth ribs, exposing the pleura of the mediastinum and the pericardium. The dressing consisted of charpie, which had been dipped in phenic oil and the permanganate of potassa. At first the case did well, the wound presenting a healthy granulating appearance, but fifteen days after the operation the patient succumbed to a hypostatic pneumonia. In the other cases the operation was performed for caries of the bone, occurring in scrofulous subjects, and in each instance the patient recovered. —*Journal de Médecine*, Aug., 1875.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

PUBLISHED BY

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, January 8, 1876.

CONTAGION IN OUR SCHOOLS.

THE prevalence and spread of scarlet fever and diphtheria among the school children of this city are facts which should awaken an anxious concern with the profession. It is unnecessary to say that the occurrence of the majority of these cases is explained by the fact of direct contagion. No matter what particular views may be advanced in regard to the modus operandi of the poison, we hardly believe there are any at all acquainted with the diseases in question who would be willing to say that they are not communicable, and hence not amenable to ordinary preventive measures. But, notwithstanding this belief, a belief shared in by the most intelligent portions of the lay community, we have these diseases cropping out in the schools day by day, under the very eyes of the teachers, and without any apparent effort on their part to arrest the spread. When a child carries a contagious disease from his school to his home there is always trouble and anxiety in the train, and not unfrequently death, besides the danger of the propagation to other members of the family and among the neighboring children. In the absence of sanitary inspection in our schools, it may seem hardly fair that we urge upon the teachers any extra duty to supply the deficiency; but we are convinced that with very little trouble on their part a great deal of good can be accomplished. And, after all, in this particular the teacher is the fittest person to act, being always in direct communication with every scholar, and being the first to be informed of any illness. It would seem to be a very simple task to send the ailing child home, and at the same time to assume, especially during epidemics, that the sickness may be of a contagious character. Neglect of such precautions causes the sacrifice of many valuable lives yearly, and so long as teachers consider that they have no moral obligations in the matter we can hardly hope for any change.

Even in the most contagious diseases the danger of infection during the initiatory symptoms is comparatively slight. This certainly is the strongest possible argument in favor of the prompt quarantining of a suspicious case. But while we allow that with the right disposition on the part of those who have charge of the children much disease may be prevented, there is another element in the question, and one which it is more difficult to meet, because in a measure beyond the control of the teacher; and that is, the premature appearance at school of those who have been the subjects of these infantile diseases. It is well known that the power of propagation lingers in many of these disorders long after convalescence has commenced, and as such a fact is one of the most difficult things for ignorant parents to appreciate, there is no wonder that many times the most dangerous poisons are sown broadcast. Any direct interference with the sending of such little ones to school would be considered as an infringement upon personal liberty, and would doubtless be strenuously combated on such grounds; but still there should be some means devised for checking the evil. We do not pretend to say what these means should be,—whether the re-establishment of sanitary inspection could effectually meet the requirements of the case, whether the Health Board could by a proper exercise of authority control this part of school sanitation, or whether to secure a more practical working to the purposed preventive system the teachers should have full authority to use their discretion in the matter. It is very certain, however, that there should be some measures adopted, especially in times of epidemics, to prevent the spread of these diseases. In the case of private schools, as the whole authority is vested in the principal, self-interest dictates a line of policy which is seldom wrong. The greatest possible care is taken to guard the scholars, and if all other means fail, the schools are closed for a time until the danger is past. This, it is true, is often done with our public institutions, but not until a large number of children have sickened and died; in other words, not until the mischief is already done which some reasonable preventive measure might have arrested at the beginning.

HOMICIDAL MANIA.

ANOTHER cold-blooded murder has been committed in one of our larger hotels, which we are told was caused by homicidal mania. The circumstances of the case, while they may seem to establish, scientifically speaking, the theory of emotional insanity, are not very assuring to the safety of those who are liable to be thrown in the way of these maniacs. An innocent man is shot by a stranger, with no provocation whatsoever; the stranger is found afterwards to be insane; and that, with the exception that a precious life is sacrificed, is about all. While there is a great deal of room for doubt in regard to the great number of criminals said to be insane, there can be no question concerning a certain few. There is, however, a very

melancholy satisfaction in discovering the latter and proving their case, inasmuch as it reflects so severely upon the policy of allowing the lunatics to go at large until the crime is committed. And yet the question as to the prevention is as difficult to answer as to the cure. Laws may be enacted to suit the emergencies of well-pronounced cases, but every now and then there will be a doubtful case as regards insanity, but a very dangerous one as regards murder.

THE PHYSICIAN'S MUTUAL AID ASSOCIATION.

Any association whose object is the care of the families of deceased medical men is worthy of our heartiest sympathy and support. The association to which we now more particularly refer, although in existence but a few years, has grown in numbers and increased in influence, so that its prosperity is assured. It now numbers three hundred and twenty-three members; has a permanent fund of three thousand dollars, with an assessment fund of over twenty-eight hundred, more than twenty-three hundred of which have been paid out to the families of deceased members.

At the annual election recently held, Dr. Mark Blumenthal was elected president; Dr. F. P. Foster, secretary, and Dr. Samuel Ayers, treasurer, with a board of trustees composed of representative and energetic men. Under the circumstances we do not see how the Society can fail to continue its prosperity, increase its membership, and extend its usefulness.

HOSPITAL APPOINTMENTS.

The exception taken to our remarks in the last number on the Presbyterian Hospital affair by a correspondent, who signs himself "One of the Eleven," deserves a passing reference. No one questions his right to an opinion in the matter, but the cause which he advocates is not strengthened by abusing the opposite side. Tact is certainly an accomplishment of which every one should be proud, and one which, exercised energetically will doubtless secure a position in the hospital; but it is hardly fair to charge those gentlemen who have been deposed with a lack of courtesy and of good behavior, since no facts upon which such a charge can be based have as yet come to light. On the contrary, if such facts could have been substantiated we doubt not that the Board of Managers would have presented them as reasonable explanations for their action. We entirely agree with our correspondent that the dignity of the profession can never be lowered by the acceptance of appointments on "well-defined, equitable, and business-like terms," but we fail to appreciate the direct application of such a remark to the hospital in question. We believe that the principle involved in the whole affair is pretty well understood by the profession, and that there is enough liberality towards the matter of opinion to allow every individual member to act as he chooses and bear his own responsibility. Any attempt, however, "to dictate public opinion," by any so-called "semi-secret club," is too absurd for sober consideration.

Reviews and Notices of Books.

THE CHOLERA EPIDEMIC OF 1873.

In accord with the joint resolution of Congress, of March, 1874, authorizing an inquiry into and report upon the causes of epidemic cholera, we have on hand an octavo of over 1,000 pages, of great value.

It consists, first, of an able essay by Dr. J. M. Woodward, U. S. N., showing the "connection of the mercantile marine with the importation of cholera into the United States, with suggestions as to the prevention or limitation of future outbreaks."

This is succeeded by the following reports:

I. History of the Cholera Epidemic of 1873 in the United States. By Ely McClellan, M.D., Ass. Surg., U. S. A.

II. History of the Travels of Asiatic Cholera. By John C. Peters, M.D., of New York. Ely & McClellan, U. S. A.

III. Bibliography of Cholera. By John S. Billings, M.D., Ass. Surg., U. S. A.

No brief notice can give adequate estimate of the value of the volume, and we shall only attempt an outline with short comments.

The essay of Dr. Woodward has the merit of direct clearness. It plainly sets forth the views of the author as to the assignation, propagation, conditions and limitations of the above. He has evidently made a very careful study of the subject. His views, therefore, are worthy of all the defence which belongs to close and ardent investigation, and yet are up for examination, rather than implicit endorsement. If his dicta are correct, we have made a stride in comprehending the disease, such as has been accomplished in reference to very few of the contagions.

His nine propositions may be thus briefly stated:

(*a*) Cholera is caused by the access of a specific organic poison to the alimentary canal, which is developed spontaneously only in Hindostan.

(*b*) Outside of Hindostan it is contained primarily only in the vomit, stools, and urine.

(*c*) Incubation is completed in from one to three days, to which alkaline nourishment is requisite, and a temperature favoring decomposition hastens it.

(*d*) Impure potable water, decomposing matter, with alkaline reaction, and alkaline contents in the intestines, favor the incubation of the poison.

(*e*) The presence of bacteria is the test of the poisonous period of the dejections.

The contagion, if dried during incubation, can be kept, and thus may be carried and introduced through air, saliva, water, or food.

(*f*) The poison is destroyed by the process of growth, or by contact with acids.

The specific character of the contagion of cholera being granted, Dr. Woodward very properly insists that every port should be informed, in advance of arrival, when there has been a shipment of passengers or goods from a cholera-infected district. This gives opportunity for the exercise of that vigilance which is generally rewarded with success. The masters of ships should have precise directions as to what to do in case

of cholera outbreak. It should be an axiom, that no diarrhœa is harmless during a cholera season. The true remedy, says Dr. W., against cholera, is preventive medicine. We would change the word "medicine" to measure or method.

We wish that we could be as certain as Dr. W. is, that "we possess in the mineral acids a certain means of prophylaxis against cholera," or that the appearance and disappearance of bacteria in excreta precisely mark their poison-period. We invite a careful study of the definite propositions of Dr. Woodward.

The clinical history of the epidemic of 1873, by Dr. McClellan, has all the value to be derived from close observation, and from a compilation of the clinical observation of manifold persons at different points, under varying circumstances and shades of type. The treatment shows all the shades that experience, fashion, and hopefulness in empirical prescription might suggest. If bacteria are tests of the time of contagion, the experiments of Nedswetzky, of Russia, are valuable as showing that chlorine water (chlorine, ℥ss.; aquæ, ℥ij.) and the mineral acids alone destroy them.

Various propositions, which nearly correspond with those alluded to by Dr. Woodward, are discussed, and similar opinions to those he presents arrived at. The time of incubation is not so definitely affirmed, and the presence of bacteria as a test of the poison-period not asserted. The contagion having been introduced, it is asserted that it is influenced by the hygienic condition of the people, and not by geological formation. No immunity is secured by one attack. It is loosely asserted that it rather predisposes to a second fatal one where there is survival at first.

Preventives of cholera are noted to be (*a*) recognitions of its infectiousness; (*b*) cleanliness, both of localities and individuals; (*c*) thorough disinfection, copperas, lime, and charcoal being especially designated; and (*d*) also great care as to dieting. Boiling, filtering, and treatment with permanganate of potash are especially noted. The diet directions are loose, and especially the assertion that wine, brandy, and malt liquors are extremely useful in moderation. The article of Dr. McClellan as a whole is excellent, but we regret to see here and there a sentence thrown in which lacks the precision which most of all we have a right to claim from those to whom Government gives special facilities for investigation.

The history of the origin and spread of the Asiatic cholera, which reached here in 1873, is very accurate and interesting. Dr. Peters shows excellent ability as a topographical historian of disease. Dr. McClellan's report as to its progress through the country is exceedingly well expressed, and the classification aids much in weighing the facts afforded by various collaborators. We have examined with interest the various testimonies of different observers. They furnish an amount of evidence which greatly aids in making up the medical history of the disease. The condition of Memphis, as reported by its health officers, is the same as that of most places where the disease proved largely epidemic. On an arrival, several cases may occur amid healthy conditions; but it does not spread in such localities very extensively, as a rule, if good hygiene abounds.

The history of the epidemics in North America, by Dr. McClellan, is also full of facts well collated and arranged. Each epidemic is treated separately, and its phenomena carefully noted. The Odessa Altenburg epidemic of 1865, which gave paternity to ours in 1866, is capable of accurate geographical description and tracing.

Dr. Woodward's report in reference to the army, shows how it spread by the movements of recruits. The history of its spread in India shows it often connected with the great festivals. No one can rise from the perusal of the book, without recognizing it as a perfect thesaurus of facts about cholera. Its careful reading is demanded by all who would study this disease thoroughly.

It is well indexed, and very many important facts can be found as to collateral causes of disease.

As to the Bibliography of Cholera by Dr. Billings, we only take exception to the idea "that the majority of readers will probably think that the magnitude of the work is much greater than its importance." If so, we pity that majority. It is a most valuable list, only too short, if it has left a single authority out. The study of cholera, like that of variola, is a typical study. Mastering it, we master whole groups of epidemics, and get a key to manifold specific diseases. Concentrated and exhaustive study upon such an epidemic schools us for laying hold of the depths of other similar studies, and so is far better than partial studies of less pronounced contagion. We well remember being in the American Medical Association, at Baltimore, within a dozen years, when great excitement was produced over the so-called *hypothesis* of specific contagion as the sole cause of cholera outside of India. In fact, medical opinion then regarded it as generally arising somehow *de novo*. Now, portability is known to be its chief, if not only, terror. It is through the close studies of pronounced and well-defined diseases that the medical world moves. A thorough differentiating diagnosis has more of treatment in its loins than we are apt to think. It is as true of diseases as of pestiferous animals, that their natural history is the first thing to consider, especially if we would put in operation effective limiting causes. We commend the whole book to the study of every lover of medical science, as well as every practitioner of medical art. When we first looked at its bulk, we were disposed to say that not expecting to meet a great cholera epidemic, we might afford to slip it in order to glean in more usual fields. But we arose from its perusal with the feeling that it teaches the law of epidemics, the importance of prophylactic treatment, and the results of prompt efficiency in managing disease, to a degree that may make us feel that the doctor is not armorless, even in the midst of assaults like those of fire, pillage, sword, and bombardment.

A Treatise on Therapeutics, comprising Materia Medica and Toxicology, with especial reference to the Application of the Physiological Action of Drugs to Clinical Medicine. By H. C. Wood, Jr., M.D., Prof. of Botany and Clin. Prof. of Diseases of Nervous System, Med. Dept. Univ. Penn., etc., etc. Second edition, revised and enlarged. Philadelphia: J. B. Lippincott & Co. 1876.

By comparing the present with the first edition of this work, there are many evidences of very decided improvement. The author has modified his conclusions in regard to the therapeutical actions of many drugs, and some of these conclusions are of considerable importance to the searcher after practical facts. Many of the sections have been almost rewritten, as much in consequence of the necessity for condensing the original text to make room for new material, as for anything else. A number of new substances have been noticed which do not appear in the first volume, and many additional facts concerning the older substances which have been necessitated by more recent investigations. Everywhere our author has given evidence of his determination to keep up to the times, some of

the references being of the latest possible date consistent with their publication in the present volume. It is needless for us to say that we are well pleased with the work in every particular. With its present improvements it may be looked upon as ranking among the leading treatises on the subject.

A Practical Treatise on Fractures and Dislocations. By Frank Hastings Hamilton, A.M., M.D., LL.D., Surgeon to Bellevue Hospital, N. Y., etc., etc. Fifth edition, revised and improved. Illustrated with three hundred and forty-four woodcuts. Philadelphia: H. C. Lea. 1875.

The reputation of this treatise is so well established that it is unnecessary to say anything in the way of general commendation. It still remains the only complete treatise on Fractures and Dislocations in the English language, and in fact in any language, if we except Malgaigne's work, which was published as long ago as 1847.

The present edition contains many marked improvements over its predecessors, to some of which we would call attention. To the already large number of illustrations thirty more have been added. The first of these, on page 181, is an original one, and gives a very correct and comprehensive idea of the usual point of fracture of the clavicle, and of the action of the muscles upon the fragments, and especially explains the effect of posture on Moore's dressing. At page 131 is introduced Kingsley's apparatus for the treatment of fracture of the lower jaw, the application of which allows of free motion of the organ during treatment. Where this latter is indicated, the apparatus in question is probably the best that has so far been devised. The author's new method of dressing fractures of the clavicle is presented on page 207, and has the merit of simplicity, if not of effectiveness. And after all, in view of the complicated apparatus that is advised for the prevention of deformities after this fracture, anything which tends towards such simplicity, and with a reasonable promise of practical utility as well, is a real improvement. Moore's theory in regard to the separation of the epiphysis of the humerus is referred to on page 233, but does not receive the unqualified endorsement of our author. One or two cases, however well observed or authenticated, are hardly sufficient to establish a radical principle. Among other new illustrations we also notice those on page 291, showing the varieties of form in which Colles's fracture may occur. An interesting case of intra-capsular fracture, caused by a blow upon the trochanter, is given, together with a woodcut. The relative merits of plaster-Paris dressing and extension with weight and pulleys in the treatment of fractures of the thigh, are quite fully discussed. Our author has taken a considerable amount of pains to express a general preference for the latter, an opinion that will, we doubt not, be shared when the present fashionable treatment shall have sunk to its deserved level. Although taking grounds against the use of plaster as a *sine qua non*, he recommends it in some forms of fracture of the femur and leg. A remarkable result of the plaster Paris treatment is presented by Dr. Gibbes's case, in which the limb was shortened until it was arrested by the lower fragment resting against the neck. We are glad to bear testimony with our author to the effect that the extension with weight and pulley has made more perfect limbs than any other method yet devised.

We have striven to give our readers some idea of the additions in the new edition, and in conclusion we would state, that as a whole the work is in every particular so fully up with the requirements of the times as to leave nothing to be desired.

A System of Midwifery; including Diseases of Pregnancy and the Puerperal State. By Wm. Leishman, M.D., Regius Prof of Midwifery, University of Glasgow, etc. Second American from second revised English edition, with additions by John S. Parry, M.D., Obstetrician to the Philadelphia Hospital. Philadelphia: H. C. Lea. 1875. 8vo, pp. 743.

In noticing the second edition of this work, it is only necessary to speak of the additions and alterations which have been made to the first edition. Notably the most important of these are to be found in the Physiological Lectures, and in the chapters on Puerperal Fever. The editor has added some remarks on the use of the forceps, already admirably presented by the author, and also upon lactation and puerperal disease, and the modifications of obstetrical instruments in this country. As a general work upon the subject, it will be found a valuable addition to the library.

Reports of Societies.

NEW YORK COUNTY MEDICAL SOCIETY.

Stated Meeting, December 27, 1875.

Dr. H. B. Sands, President, in the Chair.

EFFECTS PRODUCED UPON THE BLOOD OF SYPHILITIC PATIENTS BY TREATMENT WITH MERCURY.

The interest of the paper read by Dr. E. L. Keyes upon the above subject centred upon his conclusions from a series of observations with reference to the effect produced upon the *number of red blood-globules* by the administration of mercury in the treatment of syphilis. With regard to the value of mercury in the treatment of syphilis, Dr. Keyes assumes the following position: that syphilis is most surely controlled and most often cured by the unremitting use of small doses of mercury, just enough to restrain the symptoms without producing any conscious physiological effects, and continued for not less than two years. The drug may be pushed if symptoms seem to demand it, is often continued more than two years, and may be assisted by iodide of potassium. The opinion was expressed, that when a syphilitic patient in fair health is treated in this manner from the period of his first eruption, he may be so cured that he will have but one general eruption, and no serious lesion subsequently; that the health of such a patient will be as good after as before such treatment, and that the exceptions to the rule are not numerous. At this point reference was made to the statement of Liégeois, namely, that small doses of corrosive sublimate increase the weight of healthy men or animals. This statement has been sustained by the clinical observation of Dr. Keyes.

Reference was also made to the results obtained by Ricord and Grassi in the examination of the blood of syphilitic patients while they were being treated with mercury. The clinical experience of Dr. Keyes had seemed to contradict the result obtained by those observers. Wilbouchewitch, in an article published in 1874, gave us his conclusions with regard to the effects produced upon the blood in the early days of

syphilis by treatment with mercury. But Dr. Keyes was of the opinion that this observer had formulated his treatment for syphilis upon an erroneous interpretation of facts, and proceeded to show how his conclusions were worthless. Again, reference was made to the report of Dr. J. Hughes Bennett, in which the fact was stated, although no note made of it, that dogs increased in weight while taking small doses of mercury. In the light of the observations made by the gentlemen mentioned, Dr. Keyes began a series of experiments which extended over a period of six months, and were made upon persons in health, hospital patients, and patients in private practice. The blood was taken from 27 individuals, of which six were apparently sound and 20 were syphilitic. Only three hospital cases were used, and in them the count was made chiefly for comparison. The blood was counted 101 times, and from 5 to 10 counts made each time. The instrument used is called a *Hématimètre*. All the methods of actually counting the blood cells, to which reference has been made by writers upon this subject, whether for red or white cells, have had the defect of not accurately establishing the count for a given volume of blood. The first recorded instance where accuracy was aimed at was reported by Cramer, but his process was a rough one. Reference was made to the instruments which have been used, and a description given of the instrument employed in his own observations. The fluid used to dilute the blood for counting was made as follows: Take urine, neutral, slightly phosphatic, about 1020 sp. gr., and make of it a saturated solution with borax. Filter, and there is left a fluid with sp. gr. about 1030, which is to be diluted with water until reduced to sp. gr. 1020. The following was regarded as a better fluid, but the corrosive sublimate may render it objectionable. Take of urine, neutral or slightly alkaline, sp. gr. 1020, filter, and add gr. v. of corrosive sublimate to the ounce, subsequently decant, and reduce with water to sp. gr. 1020.

In the labor of the experiments Dr. Keyes was assisted by Dr. A. L. Stimson, and observations relating to the following points were noted:

1. *Average of red blood-corpuscles in 1 cubic mm. of blood of the healthy adult male.*—A high average is 5 millions. Anæmia rarely goes below 3 millions, and in five instances the count reached above 6 millions.

2. *Effect of small doses of mercury upon the blood early in syphilis.*—In all the cases counted, the number of the red blood-corpuscles increased under the influence of mercury, good hygiene, and tonics.

3. *Effect of the long-continued use of small doses of mercury upon the blood in syphilis.*—There were three cases: the drug was administered respectively, eleven, six, and eighteen months; the blood-count was above the healthy average, and clinically they were all in excellent health.

4. *Effect of mercury in excess upon the blood in syphilis.*—In this, the only case in which salivation had been present (produced for special reasons), the count showed a loss of one million, which was attributed to the excessive use of mercury.

5. *Effect of mercury combined with iodides upon the blood in syphilis.*—In this list it would be fair to expect frequent exceptions to the rule, that mercury increases the number of red corpuscles in the blood of syphilitic patients, because so many who need prolonged treatment late in the disease become more or less cachectic and depreciated in general health, but in only two out of the nine cases under this head did the average count fall below the normal standard, and this among patients who had had syphilis for a long time.

6. *Effect of mercury upon the blood in syphilis in hospital cases.*—There were three cases. One entered salivated, and his count increased after he began to eat. One showed a wretched count, was debilitated by disease and hospitalism, but improved under the influence of good hygiene and tonics, and it was believed that the mercury also helped him.

7. *Effect of small doses of mercury upon the blood of individuals not syphilitic.*—The observations showed an increase in the count. In testing the effect of small doses of mercury, Dr. Keyes used the protiodide in granules, gr. $\frac{1}{4}$ each (the preparation more commonly employed by him in the treatment of syphilis); and, as every person's capacity for the drug varies, one granule was administered after each meal, and increased by one granule each day (not dose) on every fourth day, until some evidence of irritation was developed, when the dose was at once reduced to one-half, and there continued at the option of the doctor. The conclusions arrived at have in the main been already given; but the following may be added to make the report more complete:

1. Mercury decreases the number of the red cells when given in excess, especially in hospital patients.

2. Syphilis diminishes the number of red cells below the healthy standard.

3. Mercury in small doses continued for a short or long period in syphilis, given alone or with iodide of potassium, increases the number of red blood-corpuscles, and maintains a high standard of the same.

4. Mercury in small doses acts as a tonic upon healthy animals, increasing their weight. In larger doses it is debilitating or fatal.

5. Mercury in small doses is tonic (for a time at least) for individuals in fair health, not syphilitic. In such individuals it increases the number of the red blood-corpuscles.

The paper being open for discussion, Dr. Bumstead remarked that he regarded the results reported by Dr. Keyes as being of very great importance, and complimented the zeal with which the work had been pursued. The only criticism which he would venture was, whether the effect produced by mercury upon a healthy individual can be taken as a standard of the effect which will be produced by mercury upon an individual suffering from syphilis.

With reference to the results which follow a long-continued use of mercury in the treatment of syphilis, his experience had differed from that of Dr. Keyes.

Formerly he had treated syphilis according to the plan of administering mercurials for six months, perhaps a year, and following with iodide of potassium, which was to be continued for two or three months. The results obtained by this plan of treatment had, in his hands, proved very unsatisfactory.

Latterly the plan of treatment which he has more frequently adopted consists in the vigorous use of mercurials for limited periods of time, and then the allowance of an interval during which no remedy, except it may be a simple tonic, is taken. After a certain length of time, variable somewhat in different cases, a return is made to the mercury, when it is again pushed with considerable vigor. Dr. Bumstead preferred this course to the prolonged use of mercurials in small doses, as recommended by Dr. Keyes, and also by Jonathan Hutchinson, of London. With regard to the excessive use of mercury in the treatment of syphilis, such cases are rarely seen at the present time.

Dr. H. G. Piffard remarked that the difference in conclusions arrived at by Wilbouchewitch and Dr. Keyes was not so broad as might at first seem, for

both observers have proved that mercury increases the number of red blood-corpuscles. Wilbouchewitch, however, administered larger average doses than Dr. Keyes, and it is quite possible that if both had used doses of the same size, they would have arrived at the same conclusions. The only difference, as their conclusions now stand, seems to be that W. claims a *diminution* in the number of red corpuscles when mercury has been too long continued, while K. has shown that an *increase* takes place. The field in which the experiments were made perhaps may also assist in accounting for this difference. Dr. Piffard referred to the fact that the white corpuscles can be much more readily counted when the blood upon the slide has been tinged with anilin. The effect produced is twofold: 1st, the white corpuscles are colored so that they are more easily recognized; and, 2d, the red corpuscles are in some way cleared out of view, leaving only the colored white corpuscles in the field. The doctor also referred to the value of the count as a means of diagnosis.

Dr. Otis remarked that although he had not had any experience with reference to the precise labor embodied in the paper read by Dr. Keyes, yet he regarded the results as an important step towards a more successful plan of treatment for syphilis than perhaps we have yet had. Mercury has been used in the treatment of syphilis rather as an antidote than otherwise, for the reason that the exact nature of syphilis was not known. It is now known that a notable increase of white blood-corpuscles is present in the blood of a syphilitic patient, and what we wish to do in the way of treatment is to get rid of this accumulation of cell elements, which constitutes one of the manifestations of syphilis. Anything that can be administered to the patient, which will clear his blood of this abnormal accumulation of white cells, will give him the most benefit.

We do not wish then to find an antidote, but something which will eliminate from the system that poison which manifests itself in an increase of these elements in the blood.

Now, mercury is known to have the power of producing fatty degeneration of healthy tissue. If it will accomplish that, we can understand how it will attack material not of a healthy nature; and we now know that when it is administered in small doses it will eliminate this material quietly, gradually, and finally clear it entirely out of the system. If any other remedies shall be found which possess the same power, or which shall meet the requirements more effectually than mercury, very well. But, in studying the effects produced by remedies, the labors of Dr. Keyes will lend a practical and positive view to their use in contradistinction to the empirical method of treatment which has heretofore obtained.

Dr. R. W. Taylor remarked that the practical value of the paper by Dr. Keyes consisted in the indisputable proof which it carried regarding the innocence of mercury when properly and carefully administered, and the beneficial effect it can produce in the treatment of syphilis.

Dr. Taylor then referred to a series of experiments which he had instituted with reference to testing the value of mercury in the treatment of those cases of syphilis in which fever is present. Syphilitic fever occurs in about one in six cases. He had found that the fever was subdued and tissue change arrested more promptly by the use of mercury than any other remedy used, and the general nutrition of the patient was at the same time improved. Quinine in large doses, iodide of potassium, iron and quinine were all used in different cases; but there was not that decided fall in temperature following their use, as was seen after the use of mercury. These facts will go hand in hand with the observations made by Dr. Keyes, which confirm the value of mercury in the early part of the secondary stage of syphilis. With regard to the use of small doses of mercury, and continuing them for a long time in the treatment of syphilis, he was fully convinced of the truthfulness of the remarks made by Dr. Bumstead.

In order to obtain the best effect of mercury in the treatment of syphilis, it should be omitted for a certain length of time and then resumed. The patient in the interval ceases to become accustomed, as it were, to the use of the drug; and, even though manifestations of quite an active character are present upon the skin, the disease will be more quickly and thoroughly eradicated, by dropping the mercury at times and allowing the patient to go on with tonics and general hygienic observances. With such intervals in the administration, mercury can be employed and a much more marked effect produced than can be obtained by its administration in any other manner.

Dr. O'Sullivan referred to two cases of syphilis in which a perfect cure, apparently at least, was effected by the long-continued use of $\frac{1}{24}$ grain doses of the bichloride of mercury, combined with iodide of potassium, and given three times a day. The size of the dose was believed to be remarkably small.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, December 8, 1875.

Dr. F. Delafield, President, in the Chair.

RUPTURE OF THE HEART.

Dr. R. E. Van Geison, of Greenpoint, N. Y., presented a heart with the following history:—

Mr. F., a very robust man of 65 years, who, from his own account, was "never sick in his life," after leaving the bedside of a dying son was taken on the morning of Nov. 19 with vertigo and vomiting. I found him in bed at 9 A.M., feeling better. Nov. 23d, I was again sent for. Found him up, but complaining of severe pain over cardiac region. Prescribed anodynes, and he soon obtained relief. Nov. 25th, he again sent for me. He had suffered all night from the pain in his chest again. Pulse 100. Murmur over the heart not well defined, seemingly aortic. At 9 A.M. prescribed opiates. At 9 P.M. found him comfortable. Had taken a little food. He expressed to his friends at 10 P.M. that he felt as well as ever. He slept until one o'clock, and then arose to urinate. He spoke cheerfully to his wife; said he felt quite well, and thought he should pass a comfortable night, and then springing into bed quickly dropped over dead.

Post-mortem held Nov. 28th, 9 P.M.

The lesion was one of rupture, apparently due to thinning of the walls from fatty degeneration. On examining the internal surface of the arch of the aorta, there were found small patches of atheroma.

Dr. Van Geison remarked that he had seen but one other case of the sort, which occurred during his naval service. The patient was a gunner, by the name of Ripley, who while asking his comrade for some tobacco, suddenly fell and died immediately. An examination in that case revealed a rupture of the left ventricle, due to the extreme thinness of its walls.

He presented a second specimen, which was of great interest in clearing up what would otherwise have been a very unsatisfactory diagnosis. The Doctor was called

very suddenly, about ten days before, to a typhoid-fever patient, who was at the time suffering from extreme dyspnœa. He found him just recovering from an attack of dyspnœa. His body was cold and clammy, pulse feeble, and it seemed as if he were in articulo mortis. With the aid of a little stimulant he rallied, and passed the night quite comfortably. The following morning he had had no recurrence of the dyspnœa, and his fever symptoms were progressing regularly. The lungs and heart were very carefully examined, but nothing was found to account for the strange phenomenon of sudden dyspnœa. About an hour after the doctor's departure, the patient was seized with another fit, but soon rallied. It was suggested that the dyspnœa might be caused by the accidental lodgment of a crumb of bread in the glottis, but his wife remarked, in combating this opinion, that the fits did not come on after eating, but while the patient was in a sound sleep.

At the end of the week, while in a coughing fit succeeding an attack of dyspnœa, the patient discharged a carious tooth, which cleared up the diagnosis at once. The tooth in question was attached to the gum by a mere shred, and had finally escaped into the throat, probably during sleep.

Dr. Van Geison, in further allusion to his first case, remarked upon the length of time which had elapsed from the initial symptoms to the death. It would seem that the rupture had commenced by a slight leakage, and finally killed the man by an overwhelming flood. The pericardium was partly filled with fluid blood, but contained no clots. In Ripley's case the blood was firmly coagulated around the heart, taking as it were a complete mould of the organ.

Dr. Beverley Robinson asked if the clot in the latter case was ante or post mortem.

Dr. Van Geison presumed that the coagulation was post mortem, as the man died instantly.

Dr. Robinson in this connection referred to the statement made that ante and post mortem clots can be distinguished by the presence or absence of the mould of the semilunar valves upon the clot.

Dr. Delafield remarked that we occasionally meet with some cases of death from rupture of the heart in which there are symptoms for several days before death. In those instances the rupture is gradual, and is oblique in its direction. In the case in question, however, the rupture was very direct, and any such explanation of the preceding symptoms could not obtain.

Dr. Loomis thought that the preceding attacks were due to failure of the heart powers. If there had been any escape of blood at first into the pericardium, the patient would have suffered from pericarditis; as it was, he had only the usual symptoms of fatty heart.

DIPHTHERIA.

Dr. A. H. Smith presented the larynx and portion of the trachea removed from the body of a medical gentleman, aged thirty-two years, who died of diphtheria on the Saturday morning previous. His illness was of ten days' duration, and during its earlier part it partook of the character of membranous sore-throat, so much so that the patient gave himself no treatment for three or four days. At the end of that time the membrane formed very rapidly upon the pharynx, uvula velum and tonsils. Then the larynx became involved, when it was also evident that the disease had extended into the air-passages lower down. He was finally tracheotomized at his own urgent solicitation, rather than in accordance with the convictions of Drs. Jacobi and Beverley Robinson, who saw the case in consultation. Dr. Smith performed the operation, with the immediate effect of relieving the dyspnœa, but the patient died four or five hours afterwards, apparently as much from the extreme exhaustion of the general poisoning as from interference of the respiration.

The specimen showed a false membrane lining the larynx and trachea, thicker in the latter. The membrane extended as far as the specimen could show, and doubtless existed in the bronchial tubes, although the circumstances of the case precluded the opening of the chest.

Dr. Smith also exhibited a section of skull removed from a dissecting-room subject, which showed a solid bony frontal sinus.

SIGNIFICANCE OF ENLARGED GLANDS.

Dr. Robinson asked concerning the significance of enlarged glands about the neck in diphtheria.

Dr. Smith replied that in connection with his case they were tender, but not enlarged.

Dr. Robinson remarked that some authorities maintain that there is a direct anastomosis of the lymphatics of the tonsils with those of the neck. If this were a fact, a very important element in diagnosis would be established, and would explain the fatal character of such cases as are attended with much swelling of these glands. The weight of authority favored the statement that the fatal cases were almost always attended with this state of things.

Dr. Van Geison remarked that the practical fact remained, that in the majority of the cases of fatal diphtheria these glands were not at all involved. In regard to this point he spoke without hesitation, his experience in this disease being quite extensive.

Dr. Robinson maintained that Dr. Van Geison's experience was contrary to his own and to the greater number of authorities on the subject. In thirty or forty post-mortems of children who had died of the disease, the existence of swollen glands was very marked.

Dr. Van Geison remarked that far from attaching any grave importance to the glandular swellings, he was almost willing, in consequence of their existence, of giving them a favorable prognosis. In the toxic form of the disease the glandular swellings were not present, and in all those cases death, according to his experience, was certain. This accorded with the experience of the members of the Kings County Medical Society, as given recently in a discussion upon the disease.

Dr. Loomis thought that the apparent discrepancy in the statements of the two preceding gentlemen could be explained by a difference in the type of disease. In the earlier cases he was confident that the fatal cases had glandular complications as a rule, but that the latter ones presented an opposite condition of things.

Clinical Teaching in Paris.—There has of late years been a well-grounded complaint of the paucity of clinical instruction in the Parisian school, and the latest reports say that measures have been taken to remedy this defect. Chairs are to be created for the clinical teaching of syphilis, diseases of the skin, ophthalmology, otology, mental diseases, and odontology, which will be established at the different general hospitals already in existence, and placed under the direct control of the Faculty, which will have the right to appoint its own professors. The appointment is for ten years, with the power of re-election, and the salary is 5,000 francs *per annum*.

Correspondence.

PRESBYTERIAN HOSPITAL AFFAIR.

To the Editor of The Medical Record.

Dear Sir:—In the last number of The Record you venture upon an interpretation of the principles of the eleven applicants for appointment to the Presbyterian Hospital. I cannot speak for all, but so far as one of them is concerned, you are in error.

I have applied for, and hope to have the opportunity to hold an appointment in that hospital, on the same terms on which all other physicians hold their professional appointments, whether as family doctors, examiners for insurance companies, or physicians to corporations (hospitals included, disguise it as you will); that is, on good behavior. And in that term I include not merely the observance of the code of ethics and the avoidance of insanity, as one of your correspondents would have it, but also the exercise of that tact and courtesy which we expect to find in successful men generally, and the absence of which has been so conspicuous in the whole of this affair.

Permit me to add, that the dignity of the profession, about which we are all so properly solicitous, is in less danger of being lowered by the acceptance of a half-dozen appointments on well-defined, equitable, and business-like terms, which offer rewards as well as penalties, than it is by ill-bred sneers at ladies, by childish fits of temper over real or imaginary wrongs, and by an absurd pretension on the part of a score or two of young men organized as a semi-secret club to the right to dictate public opinion on all questions, and to determine the reputation and standing of individuals.

One of the Eleven.

New York, *January* 3, 1876.

CHANGES IN THE PUBLIC SERVICE.

ARMY.

Official List of Changes of Stations and Duties of Officers of the Medical Department United States Army, from Dec. 26th to Dec. 31st, 1875.

White, Chas. B., Surgeon.—Assigned to duty at Columbus Barracks, Ohio, as Post Surgeon. L. O. 264. A. G. O., Dec. 17, 1875.

Merrill, J. C., Assistant Surgeon.—To report to Commanding General, Department of Texas, for assignment to duty. S. O. 264, c. s., A. G. O.

Rosson, R. L., Assistant Surgeon.—Assigned to duty at Camp McDowell, Arizona Territory. S. O. 108, Department of Arizona, Dec. 11, 1875.

Society of Neurology.—At the Annual Meeting of the New York Society of Neurology, held December 29th, the following officers were elected for the ensuing year:

President, D. B. St. John Roosa, M.D. Vice-President, Wm. H. Draper, M.D. Corresponding Secretary, Alfred L. Carroll, M.D. Recording Secretary and Treasurer, A. McLane Hamilton, M.D. Curator, Edward G. Janeway, M.D. Councillors, J. C. Dalton, M.D.; Austin Flint, Jr., M.D.; H. D. Noyes, M.D.; John J. Mason, M.D.

Medical Items and News.

New Medical Weekly in London.—We understand that a new weekly medical journal is being started in London, under the editorship of J. Milner Fothergill. The first number will appear during the present month.

The Chicago Journal of Nervous and Mental Diseases is to drop the "Chicago" and will be published in both New York and Chicago simultaneously.

The New England Psychological Society is the name of a new organization started by Dr. B. D. Eastman, of the Worcester Lunatic Hospital, and embracing the superintendents of similar institutions in the New England States. Pliny Earle, M.D., of the Northampton Lunatic Hospital, is the president, and Dr. Eastman, the secretary and treasurer. Meetings are to be held quarterly, the next one being at Worcester, on the third Tuesday in March, 1876.

The Late Professor Jüngken, of Berlin, bequeathed his collection of instruments to the Augusta Hospital of that city.

A New Sphygmoscope has been brought to the notice of the profession by Dr. E. A. Pond, of Rutland, Vt., which consists of a glass tube with a small bore, in which an index of colored fluid rises and falls with the pulse, as the large end of the tube covered with delicate rubber is made to press on the artery.

Anatomical Material in London Schools.—Some English journals are complaining of the scarcity of material for dissecting in London, none of the schools, it is said, having yet received more than half the subjects necessary to supply the men waiting to dissect.

Francis Edmund Anstie.—The inscription written by Mr. John Simon, F.R.S., to be engraved on a tablet in the Chapel of King's College, London, commemorative of the late Dr. Anstie, is as follows:

"In memory of Francis Edmund Anstie, M.D., London, F.R.C.P., Physician to the Westminster Hospital, Honorary Fellow of this College. Laborious in study, accomplished in practice, ardent in love of truth and justice, strenuous in efforts for the poor and friendless, he was stedfast, gentle, and affectionate in all personal relations, and dearest to those who knew him best. His death, which took place on September the 12th, 1874, in his 41st year, was caused by blood-poisoning incurred in the discharge of his duty."

Weekly Bulletin of the Meetings of Medical Societies.

[The Medical Record *is published every Saturday. Notices of meetings, lectures, operations, etc., intended for publication in this bulletin should be received at the office, 27 Great Jones Street, one week previous, to insure their appearance.*]

Tuesday, Jan. 11.—East River Medical Association. Election.

Wednesday, Jan. 12.—N. Y. Pathological Society. Coll. of Phys. and Surg., 23d st., cor. Fourth avenue. Election of officers.

Friday, Jan. 14.—N. Y. Medical Journal Association. "Rachitis," Dr. S. M. Roberts.

Original Lecture.

THE INFLAMMATIONS AND THE CONGESTIONS OF THE NON-GRAVID UTERUS.

PRELIMINARY LECTURE,

By E. R. PEASLEE, M.D., LL.D.,

PROFESSOR OF GYNÆCOLOGY IN BELLEVUE HOSPITAL MEDICAL COLLEGE.

Part III.

Gentlemen:—Having considered the principal obstacles to the correct understanding of my subject, I next call attention to the fact that the cervix and the corpus uteri are, in relation to it, to be mainly regarded as independent organs; and propose a more definite anatomical nomenclature of their different parts than has hitherto been suggested.

1. Recurring to the primal development of the uterus, we find that one-half of the body, and the same half of the cervix (the organ being bisected antero-posteriorly), are developed from the same embryonic source—Müller's duct—these halves subsequently meeting and blending on the median line. But the cervix is proportionately much larger at first, and so remains till puberty, since it constitutes, as it were, the basis or nucleus of the future uterus. It is therefore also firmly attached to the contiguous parts; while the body is not needed, and therefore not developed till puberty arrives.

Developmentally, therefore, the corpus and the cervix are one and the same organ.

2. Histologically, also, they are identical, being composed of the same structural elements—muscular and areolar (connective) tissue, with vessels and nerves. And they constitute but a single organ anatomically; the longitudinal fibres of the corpus being prolonged into the cervix, both anteriorly and posteriorly, and rendering the two portions inseparable by dissection.

3. But *physiologically*, the corpus and the cervix are quite independent. The normal secretion of the cervical canal is entirely unlike that of the uterine cavity; and the two great functions of menstruation and of gestation are confined exclusively to the latter, the cervix not at all participating. Parturition also is effected by the corpus uteri, not only unaided but even resisted by the cervix, whose resistance the corpus finally overcomes. The cervix is, in fact, the sphincter muscle of the uterine cavity, and therefore also prevents premature delivery.

4. *Pathologically*, also, the cervix and body of the uterus are, to a notable degree, distinct. Inflammation and congestion are very often confined to the cervix, or to the corpus, alone; and certain diseases almost always attack one of these parts to the exclusion of the other; as fibroids are mostly developed in the corpus, and carcinoma and epithelioma in the cervix. In general, the latter is more liable to disease than the corpus, and especially in the imparous woman, since in her the cervix has attained almost to its full development and vascularity, while the corpus does not till at the end of gestation. But after the return of the pregnant uterus to nearly the same size as before pregnancy, the corpus still remains far more vascular than before, and far more liable to certain pathological conditions. It will therefore be necessary, when I come to speak of the inflammations and the congestions of the uterus, constantly to point out their different symptoms and effects in the parous and the imparous woman. It will be seen that the question is not whether the woman is married or a virgin, but whether she has or has not been pregnant; or, in other words, has the uterus been, or has it not been, developed beyond the virgin state by gestation. If gestation has obtained, and parturition, whether at term or at any previous time, has occurred, I shall speak of her as a parous woman; if pregnancy has never occurred, she is of course imparous.

5. There is, however, a therapeutical interdependence of the corpus and cervix uteri; or rather a dependence of the former upon the latter. Hence remedies applied to the cervix may be found to act upon the corpus, not only by reason of the continuation of the tissues of the one into the other, but also because many of the vessels and nerves of the corpus are first sent to and through the cervix. Especially evident is this in the use of scarifications of the cervix, and in the application of leeches, suppositories, or powerful counter-irritants.

The pathological independence of the cervix and corpus uteri just illustrated necessitates a more precise and distinctive nomenclature than has hitherto been adopted; and I propose the following terms, both anatomical and pathological, as having been used in my public lectures for the last eight years.

A. The corpus uteri consists of three distinct layers from without inwards:

(*a*) The perimetrium* (or serous layer), covering the entire corpus, and also the supra-vaginal portion of the cervix posteriorly.

(*b*) The metrium, including the muscular and the connective tissue.

(*c*) The endometrium—the mucous membrane lining the uterine cavity.

B. The cervix also has three layers from without inwards:

(*a*) The peritrachelium,†—the mucous membrane covering the whole of the vaginal portion, but wanting on the supra-vaginal.

(*b*) The trachelium, including all the muscular and connective tissue of the cervix.

(*c*) The endotrachelium—the mucous membrane lining the cervical canal.

Thus the endometrium, the endotrachelium, and the peritrachelium constitute the entire mucous element of the uterus; and the metrium and the trachelium, the parenchyma, so-called, of the corpus and the cervix respectively.

The nomenclature of the diseased conditions should, of course, correspond with the anatomical terms; and we recognize three inflammations of the corpus and three of the cervix, viz.:

I. *Of the corpus.*—Perimetritis, ‡ metritis, and endometritis.

II. *Of the cervix.*—Peritrachelitis, trachelitis, and endotrachelitis. §

The accompanying diagram illustrates the application of the terms just given.

There are also, with reference to their locations, six different congestions of the uterus, viz.:

---

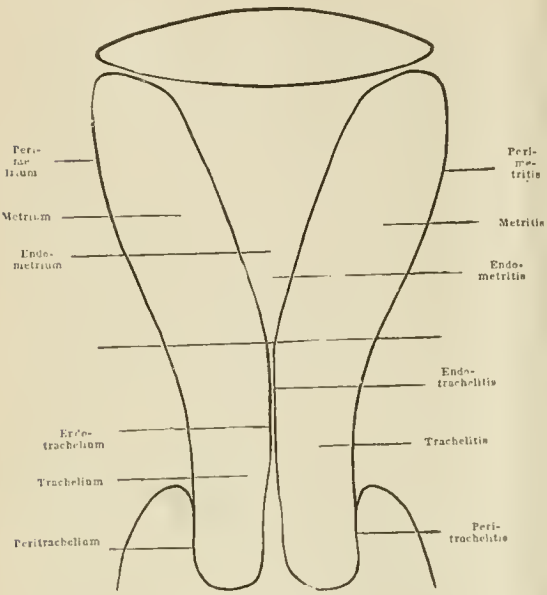
* From περί, *around*, and μήτηρ, uterus. This term and endometrium have now become familiar.

† From περί, *around*, and τράχηλος, the neck.

‡ This term is used in an indefinite way by Dr J. M. Duncan, as synonymous with pelvic peritonitis; while parametritis was selected by Virchow for pelvic cellulitis. Metritis is now familiar, but not as here defined and restricted. Endometritis has been in use for about fifteen years.

§ Termed endocervicitis by some writers; a barbarous compound of Greek and Latin.

Of the corpus.—The perimetric, the metric, and the endometric.



Of the cervix uteri.—The peritrachelic, the trachelic, and the endotrachelic.

These congestions I next proceed to consider.

THE CONGESTIONS OF THE NON-GRAVID UTERUS.

These will be considered before the inflammations, since they are vastly more common and more important. Besides, the latter are generally preceded by congestion, for a longer or shorter time, as their predisposing cause.

Active congestion of the uterus during the menstrual period, and for two or three days before and after it, is a normal condition of that organ; but when it or the passive form further trenches upon, or extends through, the intermenstrual interval, it becomes a pathological state, and demands appropriate treatment.

Thus explained, uterine congestion is found to be the most common affection of the uterus; and probably, indeed, is more frequent, when found alone and when complicated with other affections, than all the others counted together. Moreover, it may exist, not only for months, but for many years, even through the thirty years of menstrual life; thus entailing a greater amount of suffering in the aggregate than any other disease to which woman is liable, until the health is irremediably ruined.

It is therefore singular that its existence has hitherto been almost entirely ignored; while it is universally conceded that all other vascular organs are subject to congestion. With the sole exceptions of Dr. Chapman, whose work was published in 1872, and Dr. Barnes (1874), no gynecological author has recognized congestion of the uterus as a pathological condition requiring any special treatment;* though by several the phrases "active congestion" and "passive congestion" have been incidentally used, as admitting its possible or actual existence. But most writers have ignored its existence entirely.

But the reason for this omission has already been explained; and was also stated by myself in a discussion upon chronic metritis, in the New York Academy of Medicine, in 1866, in language to the following effect:

"I desire here to make a plea for the uterus, and defend its right in common with all other very vascular organs to become congested—a right which all authors up to the present time, and the speakers on this occasion, deny or ignore; and to assert that chronic metritis, so-called, is nothing more, nothing less, and nothing else, than chronic uterine congestion, with its results." I also now add, that the uterus is far more liable than any other organ to become congested pathologically and chronically—the ovaries even not excepted; as might be expected, *a priori*, of an organ which is habitually congested at least seven days in each month, or about one quarter of the time.

* Some slight attention had previously been called to uterine congestion by Ashwell, Simpson, and Grailey Hewitt only; of whom Ashwell alone alluded to its treatment, and this in but a dozen lines. Dr. Barnes devotes four pages to congestion and its treatment (pp. 429–433). None of these writers distinguish between active and passive, or recent and chronic congestion, nor indicate the particular part of the uterus which is congested in particular cases.

Original Communications.

REPORT OF A CASE OF PERITYPHLITIC ABSCESS IN THE ILEO-CÆCAL REGION,

TREATED SUCCESSFULLY BY THE EARLY ESTABLISHMENT OF AN EXTERNAL OPENING IN THE ABDOMINAL WALLS FOR THE ESCAPE OF PUS.

By GURDON BUCK, M.D.

Mr. J. M., æt. 26, of Liverpool, of good constitution and regular habits, being in good health and free from any premonitions of the attack that was impending, returned on Monday, Nov. 8th, 1875, to the city from Philadelphia, by an early morning train, took his ordinary dinner at half-past six in the evening, and retired to rest at about eleven o'clock. After a good night's sleep he was awakened in the morning of Tuesday, 9th, by pains in the right iliac region, which he described as a peculiar sensation rather than pain, and which he feared might be the precursor of an attack of colic such as he had experienced on two previous occasions, but at remote periods. He had two small loose evacuations following each other after a short interval. Hoping to obtain relief by provoking vomiting he drank freely of hot water, which he rejected unmixed with other substances. The pain increasing in severity he resorted to hot fomentations. At 9 o'clock he was visited by Dr. G. H. Wynkoop, who prescribed six grains of calomel and administered a hypodermic injection of Magendie's solution of morphia, and repeated it a second time, later in the day. The same evening, about twelve hours after the attack, I made my first visit, and found him suffering from very severe pain in the right iliac region, which had persisted all day. He had vomited two or three times some bilious matter subsequent to the vomiting produced by taking hot water in the morning. There was no febrile heat nor acceleration of the pulse, nor had there been any rigor. The abdomen was supple, but extreme tenderness on the slightest pressure existed over a spot that could be covered with the thumb at a point three fingers' breadth distant from and to the inside of the anterior superior spinous process of the right ilium, and on the same level

with it. The tenderness diminished in a marked degree as the pressure receded from this circumscribed spot. Suspicion of the existence of a lesion of the vermiform appendage was excited. Without delay one dozen leeches were applied, and followed by hot fomentations.

Second day, at 9.30 A.M.—Visited Mr. M. with Dr. Wynkoop, and found him still suffering severe pain by paroxysms, and with the same exquisite tenderness on pressure over the spot already indicated in the right iliac region. He had had a shiver, lasting ten minutes, since daylight. Pulse had risen to 106 and temperature to 101°. A second application of six leeches was made, and poultices were continued. A narcotic treatment was now instituted. Magendie's solution of morphia was directed to be taken, 15 minims every hour, till narcotism was produced, and thereafter to be continued every two hours. At 7.30 P.M., patient was more comfortable and suffering less pain; there was less tenderness on pressure; he had not vomited for 24 hours past. Pulse was reduced to 86. Temp. 100⅘°. A moderate degree of narcotism has been maintained by 75 minims of Magendie taken since morning.

Third day, at 9.30 A.M.—Has passed a comfortable night without severe pain; tenderness on pressure is less marked; its locality, however, is unchanged; has vomited bile. During our visit he had an attack of severe colic pain, diffused over the abdomen. The abdominal muscles were tense and retracted; pulse 98. Temp. 99° to 100°. Has taken 60 minims of Magendie through the night, up to eight o'clock this morning. Ordered enema of infusion of catnip and the use of the catheter to relieve fruitless efforts at urination. Ordered to take calomel, gr. x.

At 7.30 P.M., patient somewhat relieved after the operation of the enema; has succeeded in urinating. The abdomen has now became tumid. Local tenderness not increased; the surface of the body is moist. Dysuria persistent. Pulse 98. Temp. 99°. Morphia has been taken in increased quantity through the day; but the original dose of 15 minims is to be resumed again.

Fourth day, at 9.30 A.M.—Has passed the night without severe pain. Pulse 94. Temp. 99°. Abdomen still tumid. Is much disturbed by nausea, evidently aggravated by the morphia. It was therefore stopped. Ordered calomel gr. ij., bismuth sub-nitrate gr. v., to be repeated three times at intervals of three hours. At 7.30 P.M., has taken no morphia since 6 A.M. without increase of pain; nausea persists. Pulse 84. Temp. 98°. Ordered sinapism to epigastrium, ol. ricini ℥ss., and enema of infusion of catnip.

Fifth day.—Pulse 84. Temp. 98° morning and evening. Flatulence and nausea persist. Abdomen tumid. Cap. calomel gr. ij., sodæ bicarb. gr. v., every four hours.

Sixth day, at 9.30 A.M.—Continued flatulence and nausea, with eructations accompanied by severe colic pains. Pulse 102. Temp. 101°. Stopped calomel powder, of which he had taken six. At 7.30 P.M., no decided relief. Ordered ol. ricini ℥ss., and an enema of catnip, to be administered through an O'Beirne rectum tube, inserted high up.

Seventh day, at 9.30 A.M.—The severe colic pains continue. Pulse and temperature abated. At 8.30 P.M., Prof. Alonzo Clark joined us in consultation, and after a careful examination of the patient, confirmed the diagnosis already arrived at. By careful percussion he outlined a dull space upon the surface identical with the seat of local tenderness, but unaccompanied by any elevation on the surface corresponding to it. He also defined by palpation the outlines of a deep-seated tumor of somewhat firm consistence, the centre of which also corresponded to the tender spot on the surface. Patient's sufferings were further aggravated by the development of an inflamed swollen hemorrhoid, occupying the right half of the verge of the anus. It was split into two halves by transfixing it lengthwise at its base with a sharp-pointed bistoury, and cutting outward through the surface. An enema of 20 drops of Magendie's solution was then administered.

Eighth day, at 9.30 A.M.—Patient had passed a distressing night, chiefly caused by the hemorrhoid, but obtained some sleep toward morning after a hypodermic injection of morphia. Has had several free liquid evacuations, and has vomited two or three times; the abdomen has now become more supple. Pulse 98. Temp. 99° to 100°. At 7.30 Prof. T. M. Markoe joined our consultation, and also confirmed the diagnosis.

Ninth day, at 9.30 A.M.—Patient passed a better night, more free from pain. No vomiting, no eructations. Takes more liquid nourishment. Pulse 72. Temp. 98⅕°. At 7.30 P.M., pulse 68. Temp. 98°.

Tenth day.—A good night. Pulse, morning and evening, 61. Abdomen less tumid and more supple. Local tenderness on pressure is again becoming more marked; its centre of greatest intensity remains at the same point.

November 19th, eleventh day.—At 1.30 P.M., Prof. Clark met us again in consultation, with special reference to an operation. Patient's condition was as follows: The tumidity of the abdomen had subsided to such a degree, that the surface between the umbilicus and crest of the right ilium, from being elevated, had become sunken. The deep outlines of the tumor could be more easily distinguished by palpation, though there was still no circumscribed elevation upon the surface at the point where the greatest sensibility to pressure existed. No fluctuation was perceptible, nor was there any redness of the surface nor adhesion of the skin to the underlying parts. Instead of dulness, there was now resonance on percussion over the seat of greatest sensibility. This condition of resonance, conflicting as it did apparently with the supposed presence of suppuration, might depend, as afterward proved to be the case, on the co-existence of gas with pus in the cavity of the abscess. This apparently conflicting condition did not, however, deter from the proposed explorative operation, which was performed as follows:

Operation.—Before the inhalation of ether was commenced, the precise seat of greatest sensitiveness under digital pressure was once more determined and located, as it had uniformly been, by daily repeated previous examinations, midway on a line between the umbilicus and the ant.-sup. spin. process of the right ilium. After complete anæsthesia and relaxation were produced, the deep-seated outlines of the tumor were again confirmed by a more thorough palpation than had been admissible at previous examinations. At the point chosen upon the surface a puncture was made through the skin with a bistoury, to facilitate the onward progress of a sharp-pointed canula of the size of No. 1 bougie scale, which was advanced cautiously through the aponeurotic and muscular parietes of the abdomen to a depth of more than one inch, when pus escaped by the side of the canula, and immediately after through the canula itself. The canula being held *in situ*, served as a guide, upon the outer surface of which a sharp-pointed bistoury was conducted into the cavity of the abscess, and the opening enlarged. At the same time the

external wound was also enlarged by dividing the skin and underlying parts to the extent of nearly two inches. A dressing forceps was then introduced with closed blades, and withdrawn with the blades opened, so as to enlarge the entrance of the abscess. A free discharge of grayish fœtid pus, without stain of bile, to the amount of more than an ounce, followed, together with an abundant escape of gas. A finger was next inserted into the wound to enlarge still further the opening and explore the cavity of the abscess, which was found to extend in every direction laterally beyond the reach of the finger; its opposite wall, however, was reached by the end of the finger, but nothing definite was ascertained by it. A plug of cotton wick well greased was inserted, and left in the opening to maintain it free, and poultices were directed to be continued. In the evening patient was found comfortable, and his pulse at 84.

Second day after operation.—Had passed a good night, and taken food with some appetite. Removed the plug, and gave exit to a copious discharge of brownish matter, followed by thick laudable pus. Pulse, 82; temperature, 99⅘°. Replaced the plug, which was thereafter to be kept in only during the day and left out at night. On the third day poultices were discontinued, and a dressing of simple cerate substituted. The abscess was injected with salt and water, and the injection was to be repeated on the two following days. On the fourth day a particle of greenish fœcal matter of the size of a split pea was expelled with the injection. On the fifth, sixth, seventh, and eighth days small tufts of sloughy tissue, ascertained to be connective tissue by microscopic examination, were discharged, the suppuration continuing healthy and abundant. On the twelfth day suppuration no longer proceeded from the cavity of the abscess, but from the external wound alone, which was steadily filling up and contracting. Patient's general condition steadily improved, after the opening of the abscess, under the use of generous diet and the citrate of iron and quinine, gr. v., ter in die, as a tonic. On December 4th, the fifteenth day, he was able to be removed to the house of a friend in the vicinity of the Central Park.

December 17th.—The wound has healed, and patient has resumed his out-of-door life.

Remarks.—The conditions upon which a diagnosis was based in this case were the following: 1st. The abrupt onset of the attack without any premonition of its approach. 2d. The early development of acute local sensibility referred to the ileo-cœcal region, and restricted within a small circumscribed space, where the slightest degree of digital pressure could not be tolerated. 3d The uninterrupted persistence of the acute local sensitiveness within the same restricted limits, as was verified on each succeeding day, by carefully repeated exploration up to the day of the operation. 4th. The recognition of a deep-seated circumscribed tumor of rather firm consistence, indistinctly definable in the earlier stages of the disease, owing to the general tumidity of the abdomen, but becoming more clearly outlined as the tumidity subsided, and the abdominal parietes became more supple. The centre of the deep-seated tumor also corresponded to the focus of greatest sensibility on the surface. It was not, however, until the eleventh day after the attack that the deep outlines of the tumor could be defined with such a degree of distinctness as to determine the writer to resort to an operation for establishing an external opening in the abdominal walls, and the operation was then undertaken, notwithstanding the absence both of fluctuation and elevation of the surface over the tumor, and also notwithstanding the presence of resonance on percussion over the tumor, where previously there had been dulness, the resonance being attributable to the coexistence of gas with pus in the cavity of the abscess. It was a matter of regret in this case that a digital exploration per anum was rendered inadmissible by the presence of an inflamed and very sensitive hemorrhoid.

Symptoms.—In a retrospect of the progress of the symptoms in this case, it is interesting to observe that constitutional reaction was first noticed twenty-four hours after the attack, when the pulse had risen to 106 and the temperature to 101°. Twelve hours later, and after a second application of leeches had been made and the narcotic treatment put in operation, the pulse had fallen to 86, and the temperature to 100⅗°.

On the third day the pulse was 98, temp. 99°.

On the 4th and 5th days the pulse was 84, temp. 98°.

On the 6th day the pulse rose to 102, and the temperature to 101°. On this day the distressing colic pains, with eructations and nausea, reached their maximum of intensity, and the tumidity of the abdomen its greatest degree of development. On the 8th, 9th, and 10th days the pulse subsided to 78, 72, and 64, and the temperature to 99°, 98⅕°. On the day of the operation (the 11th of the disease), the pulse was 82, and the temperature 99⅕°.

The uniformly moderate rate of the pulse and temperature, notwithstanding the severity of the abdominal pains, indicating as it did the absence of inflammatory action affecting the peritoneum, afforded a sure ground for hope of a favorable prognosis.

Treatment.—Mr. Jas. Burne, in Vol. XX. of the *Transactions of the Med.-Chir. Society of London*, judiciously cautions against the energetic depleting treatment in the onset and early progress of the disease that might be applicable to acute idiopathic peritonitis. The object of the treatment should be to moderate the production of pus, and thereby diminish the strain upon the adhesions that wall in the abscess, and shut it off from the general peritoneal cavity, till the favorable moment arrives for giving it exit by an external opening through the abdominal walls. In the present case these views of treatment were carried into effect by two applications of leeches to the seat of disease; the first of twelve leeches at the expiration of twelve hours after the attack, the second application of six at the expiration of twenty-four hours, followed by poultices. The narcotic treatment was commenced twenty-four hours after the attack by the administration of morphia, and continued at regulated intervals for forty-eight hours, after which it was only occasionally repeated by hypodermic injection to allay severe pain. At no time was narcotism urged beyond a somnolent condition, from which patient could readily be aroused when spoken to. The administration of calomel was carried, perhaps, farther in this case than would be advisable in all cases. The distressing colic pains with eructations and nausea, together with indications of deranged hepatic functions, constituted a complication in his condition, which it was hoped might be corrected by mercurials. The fæcal evacuations, sometimes copious, which followed their use, certainly alleviated his sufferings, and were not accompanied by any injurious effects. The present case is the second, in which the writer has successfully established an external opening in the abdominal walls for the evacuation of an abscess, by a modified procedure differing in certain respects from the method originated and employed by Prof. Willard Parker in 1867, and repeated since by others.

IRIDOTOMY

BY

WECKER'S FORCEPS-SCISSORS.

By HENRY D. NOYES, M.D.,

NEW YORK.

An eye from which accident or operation has removed the crystalline lens and been the occasion of severe inflammation, furnishes a case whose treatment is often extremely embarrassing. After the symptoms of reaction have passed away the situation is as follows: The iris has become infiltrated with exudation which has been converted into connective tissue, and is in a state of latent hyperæmia; the pupil is shut by a neoplastic membrane, and is often dragged out of its place toward the wound which was the beginning of troubles; the lens capsule is thickened, and adheres to the posterior surface of the iris, and adds to the thickness of the pupillary obstruction; the ciliary body is hyperæmic and irritable. This picture, in variable shades of aggravation, portrays the problem which confronts the surgeon who desires to confer sight upon an eye whose deeper parts are sufficiently sound, and which only needs a suitable aperture to give entrance to light. Many methods have been devised to make the artificial pupil for this case. Every operation which causes traction at the periphery of the iris is sure to be unsuccessful, because the ciliary body is thus irritated. Some of the means which have been useful are Agnew's operation by a stop-needle and hook—an operation by two hooks pulling from the centre of the iris toward the margin, which I devised—removing a piece of iris at one sitting, and subsequently attacking the membrane which is uncovered—iridotomy by a broad needle or narrow knife, as recommended by Graefe. While success has been attained by all of these methods, failure has attended upon them all in some instances.

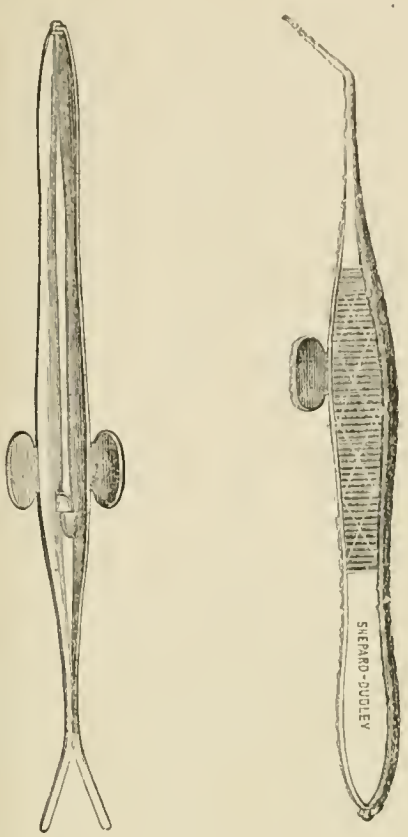
The failure comes in the form of renewed inflammation of iris and ciliary body, sometimes accompanied by hemorrhage into the anterior chamber, by which a fresh membrane is formed, and the opening established becomes again obliterated.

Dr. Wecker, of Paris, has published his results in performing an operation which has marvellously overcome the difficulties of this troublesome condition. His method is iridotomy by a scissors of peculiar construction. I have tested this proceeding in twenty cases, and feel constrained to let it be known how satisfactory I have found it to be. Up to within a week not one case had turned out badly, so far as the merits of the operation are concerned. This one bad case has just occurred, and will be properly related. It does not furnish any argument against the merits of the operation, but proves what mischief may come from an imperfect instrument.

Iridotomy, as its etymology imports, is merely cutting into the iris or obstructing membrane, without removing any portion of it. It is an entirely different proceeding from iridectomy, and manifestly can be resorted to only to divide adhesions of the iris to the cornea, or to secure an opening in the iris when the lens is wanting.

It may be done by a broad needle through the cornea, or per scleram behind the iris; but this simple form of the operation is successful only in the less severe cases. A bent and double-edged knife, which Graefe suggested, is convenient, but does not really modify this method.

The use of scissors is an old suggestion, but they have not found favor. The Wecker scissors are constructed more after the fashion of sheep-shears than of the usual instrument, and are represented in the diagrams.



Their general form is like the iris-forceps introduced by Liebreich some years ago. It requires skilful workmanship to make them properly. The blades must, of course, be delicate and sharp, but they must be so set that the edges rub firmly against each other from heel to point without missing exact contact for a tenth of a millimetre. They always creak as they are closed, and will cut the finest fibres of loose floss silk without failure. With such an instrument, *and no other is fit to be used*, Wecker's operation is a surgical triumph.

He uses a narrow and thin-edged lance-knife to make a wound at the margin of the cornea, about five millimetres long. He has had knives made with a stop, so that the wound shall always be of the right length. It is not essential to employ them, but the knife must be thin and keen. When it has made a wound of the proper length, it is partially withdrawn, and as aqueous humor escapes, and the iris approaches the cornea, is again pushed forwards to make an opening into the iris. Then it is quickly pulled out, and the scissors are taken in hand. They work equally well with both the left and right hand of the operator. They are passed into the anterior chamber with shut blades, and then allowed to open so that one blade shall go behind, and another in front of the iris. Some tact is needful to give easy play to the blades, but however they may be held, they cut whatever tissue lies between them with great certainty. It is advisable in almost every case to make two cuts at an

acute angle with each other, like the letter V. The second cut is the more difficult. The opening thus made is of irregular outline, sometimes like an arrowhead, sometimes like the shape of a bicuspid tooth, the roots being often of unequal length. If only one cut be made the tissues may not retract sufficiently, but with two cuts an ample pupil may be secured.

It is not uncommon to have a small loss of vitreous humor: from this occurrence I have never seen ill results. Hemorrhage of any importance I have not experienced. Recovery from the operation has been prompt, and never attended by serious reaction, with one exception. Usually less than a week suffices to dismiss the case. This circumstance constitutes one of the special recommendations of the proceeding, and this will appear more distinctly by reference to cases. In only one case have I failed to secure a satisfactory opening through both iris and capsule. This will be duly narrated and explained.

I began to perform this operation in March, 1874, and my last case was done November 19, 1875—in all twenty cases.

The cases on which I have operated have been of two classes: 1st, occlusion of pupil, with attachment of the iris to thickened capsule and absence of lens; 2d, adhesion of iris to the cornea.

Of the first series I will cite the following illustrations:

Case 1.—Mrs. J. H., æt. 78. Had had cataract removed from both eyes, without any improvement of sight. Severe inflammation had occurred, by which one eye had atrophied, and the other had imperfect perception of light. In the latter the lower two-thirds of the cornea was opaque, and what of the iris appeared through the upper third was atrophied; the globe a little soft. This unfortunate condition of both eyes was due to the previous poverty and the unmanageable disposition of the patient. She was, in fact, insane. The operation done on March 11, 1874. A good pupillary opening obtained, and the eye recovered very promptly. No improvement was obtained in vision, because of the unhealthy state of the interior of the eye. The case was operated upon to test the feasibility of the operation, and was in this respect encouraging.

Case 2.—Mrs. B., æt. 56. Was operated on for cataract by Graefe's method in 1872, and obtained vision $\frac{2}{70}$ in both eyes, with the ability to read Snellen II. at twelve inches. In June, 1874, the pupil of right eye was found drawn high up to the cicatrix and obscured by a dense membrane, permitting only perception of light. The left pupil was covered by a thinner membrane, and vision was $\frac{1}{100}$. Upon the right eye iridotomy, with a single cut by the scissors, gave an opening which, at the time, seemed abundantly large. But the next day the edges of the pupil had approximated to such a degree as to give a less satisfactory result than was hoped for.

In a week patient was discharged, able, with this eye, to count fingers at six feet. In the left eye keratonyxis restored vision to $\frac{2}{70}$.

Case 3.—Mrs. C. J. Extraction of cataract by Graefe's method, in October, 1874, followed by suppurative iritis and closure of pupil. In February, 1875, a double iridotomy done; reaction very moderate; a clear pupil of sufficient size obtained. A small tag of iris occasioned some inconvenience by its swinging motion. With + 4, vision = $\frac{2}{100}$. The vitreous was found to be hazy.

Case 4.—Mrs. E. S., æt. 83, had an extraction of cataract by Graefe's method, in May, 1874. Exudative iritis followed, and it was two months before patient was discharged, and her health, which at best was very feeble, was much reduced by diarrhœa. In about five months she was seen again, and found to have vision of $\frac{1}{6}^{2}$ with + 3. The pupil drawn upwards, and covered by a thin membrane. In five months longer the membrane had thickened, and vision greatly reduced, so that she could not read any common type. The membrane was attacked by two needles, but no sufficient aperture could be made. Five days after the keratonyxis, double iridotomy made, and a large pupil obtained. Vision $\frac{1}{100}$; the vitreous found to be filled with opacities. Extreme age and infirmity made this case most unpromising, and the measure of success which was achieved was due to her indomitable pluck as well as to the suitableness of the operation.

Case 5.—Mrs. E. S., æt. 76. Graefe's extraction, Dec., 1874, followed by a slow iritis; discharged after a month, with vision $\frac{2}{100}$, with + 4. In April, 1875, the pupil was dragged upwards, and occupied by a membrane.

By a double iridotomy, under which the membrane gave way readily, a clear, large pupil was obtained. No reaction ensued; patient discharged in five days, with vision $\frac{2}{70}$ with + 4, and able to read Snellen IV.

Case 6.—Mrs. N., æt. 45. Extraction of cataract by Graefe's method, in Feb., 1874, followed by exsudative iritis and occlusion of pupil. Patient only able to count fingers at three feet. A year afterwards I made a double iridotomy, whose result was a pupil of the size and shape shown in the diagram and which may serve as an illustration of the form of pupil commonly made. With + 3½ vision = $\frac{2}{40}$.

Case 7.—Boy, æt. 9, had his left eye injured by a piece of iron, which passed through cornea and iris, and caused cataract. The lens was absorbed, and the sight was obstructed by a thick capsule and the partial closure of the pupil. The iris was adherent to the outer part of the cornea, where the foreign body entered, but not adherent to the capsule. By double iridotomy the iris and capsule freely divided. The result was that the opening in the iris was enlarged, but the cuts in the capsule reunited, and left an obstructing membrane as intact as before.

The lesson from this case is, that mere division of a capsule not adherent to the iris will not secure an opening. The method must be one of dilaceration, or of extraction. I have very many times extracted such capsules by a small, sharp hook, which is an operation of some delicacy. I have in one case had a perfectly satisfactory result by attacking the membrane from behind with a long straight needle passed through the sclera, as was formerly done in reclination of hard cataract. The membrane was torn, and so far displaced into the vitreous as to leave the pupil free and vision good. I am of the opinion that this proceeding may be well and safely adopted in certain cases.

Since the above was written, another case has fallen to my experience which it is needful to narrate. It is the only one in which a disastrous result has occurred, and points out strongly the dangerous element in cases of secondary cataract.

Case 8.—Mrs. W., æt. 65, has had extraction of cataract in both eyes. The healing process was slow, and iritis occurred, followed by some thickening of capsule. In one eye a needle-operation secured a good opening and perfectly satisfactory sight. In the other eye reading was impossible, although it could count fingers at several feet distance. At my advice

the patient submitted to iridotomy. It should be remarked that the iris was caught in the cicatrix and presented a small black prominence. As soon as the eye was touched with fixation forceps, a decided injection appeared, showing that the ciliary body and iris were in a condition of chronic hyperæmia and irritation. This would have been accepted as a contraindication to any other mode of operating, but by the method intended a valuable degree of relief was to be expected, because the adhesion and dragging upon the ciliary region would be loosened. The incision in the cornea was made with some difficulty, because the knife proved dull. The first cut in the iris was easily made, and gaped widely. In making the second cut the scissors failed to sever the relaxed membrane completely; a small tag of tissue remained, and in trying to divide it a little pull was made upon the opposite periphery, which caused hemorrhage from the region of the ligamentum pectinatum. After completing the operation the scissors were examined and a spot was found near the end of the blades where they did not forcibly press upon each other and creak when the edges passed. This defect accounted for the imperfect work of the instrument, and occasioned the traction on the iris.

During the following night severe pain occurred, suppurative irido-keratitis was set up; the pupil choked with yellow exudation, and the cornea hazy. The severe pain was much relieved, and the symptoms abated by an incision about 6 mm. long across the lower border of the cornea with a Graefe's knife. Hot fomentations were freely used, and the inflammation passed its climax in about four days. The result was, to leave the eye in a condition worse than it was before the operation.

The lesson to be taught by this case bears most upon the precision with which the operation should be done, and the perfection of the instrument. The same amount of ciliary irritability was present in other eyes as in this case, and no evil effects succeeded the operation.

It would be tedious to adduce any more cases of this description. I may remark that all the operations except the last have been done with the aid of ether. Loss of vitreous has occurred in several cases, but this has never had a bad effect on the result so far as I could judge. In one man the vitreous was almost wholly fluid, and about one-half of it flowed out of the globe during the manipulation. The eyeball collapsed to a degree which much embarrassed the operation, but good success ensued.

In conclusion, I will relate some cases where this operation has been used for separating adhesions of the iris to the cornea.

Where the adhesion is small and the iris healthy, iridectomy best fulfils the indication and gives the best pupil. For the worst cases, in which the iris is atrophied and largely engaged in the corneal tissue, iridotomy has served admirably. One case in illustration will suffice.

Case 9.—James McK., æt. 34. In childhood had severe kerato-iritis of both eyes. The right cornea was perforated and the whole pupillary circle prolapsed. The lower half of the cornea became densely opaque, the upper half clear; the iris atrophied and tense.

In the other eye cataract occurred, and it became very desirable to render the sight available. The patient had been under my care in 1863, and I had operated on both eyes by iridotomy. Marked benefit was gained in the left, but none in the right.

Upon this latter I did iridotomy in July, 1875. A full, free pupil was obtained, no unpleasant reaction followed; the patient able in a week to go home. The degree of vision recovered was small, because the vitreous proved to be hazy. But the patient could go about alone, and placed his dependence on this eye.

There is no special difficulty in doing the operation upon these cases. One may, however, be disappointed in the size of the opening after the section. Sometimes the iris does not retract at all, although severed from the cornea, and it will retract only in cases where its fibres are upon the stretch. If the iridotomy do not give a proper aperture, it prepares the way for a successful iridectomy at a subsequent period.

The merits of Wecker's operation are favorably remarked upon by Prof. Becker in the last fasciculus of Graefe and Saemisch B. v. Erstehälfte. 3, 428; and Mooren (Ophthalmologische Mittheilungen aus 1873, Berlin, 1874, p. 80) reports having done 22 operations, in all of which, except two, satisfactory results ensued. The two exceptional cases were not failures of the operative proceeding, but failures to restore sight—in one because of choroidal disease, in the other because of an accidental inflammation, which subsequently occluded the pupil.

FRACTURE OF THE INTERNAL MALLEOLUS, WITH DISLOCATION OF ANKLE-JOINT.

By PHILIP A. BISSELL, M.D.,

MAHANOY CITY, SCHUYLKILL CO., PA.

The forepart of September last I was called to see Elijah Brayford, and found that he had dislocation of the left ankle-joint, the tibia resting upon the centre of the foot. I attempted the reduction, and made it *à la* Hamilton (page 710), and to my surprise it immediately returned to the same condition in which I found it, as soon as I loosed the foot. I immediately reduced again, thinking that the first time I had not succeeded, when the same thing took place again. Upon a careful examination I found a fracture of the projection of the internal malleolus, and as I attempted reduction the end of the bone had turned directly between the tibia and astragalus, forming a wedge, throwing the bone out of place as often as I would forcibly put it there. By careful manipulation I succeeded in dislodging the fractured end, and effected the reduction, the leg maintaining its position on the foot; also returning to place the fractured end of the malleolus. In six weeks he was able to walk with staff, and an examination to-day, Nov. 24th, about ten weeks after the accident, shows no deformity of the limb. Was not the case of Earle, as cited by Hamilton, which he lost by amputation, the same or similar? It occurred to me as being parallel, and only presenting this feature, which induced me to report it for publication.

The Imperial Board of Health in Germany.—A sum amounting to about $4,000 has been appropriated to the establishment of a Supreme Board of Health for the German empire, the principal object of which will be to collect reliable statistics in sanitary matters, although it is reported that the board is also to be a sort of sanitary court of appeals, to which the district administrative boards or provincial governments will have to refer for sanitary advice and decision. It is also reported that Dr. Strack, Prince Bismark's private physician, will be the president of the board.

Progress of Medical Science.

Mammary Papillæ as Signs of Pregnancy.—Dr. Vedeler has collected some interesting statistics on this point, having examined the breasts of women at various periods of their life. The breasts of 20 females, between the ages of 11 and 16, were first examined. In 12, whose breasts were not developed, he found no traces of papillæ. In 6, whose breasts had commenced to develop, he found slight papillary elevations. In 2, who had moderately well developed breasts, there were from 3 to 8 papillæ, each the size of a pin's head. Surprised by these phenomena, and thinking they might have been the result of some irritation by which the activity of the breast had been aroused, he examined 60 women who had never been pregnant. Of these 55 were unmarried, and of them 44 had papillæ and 7 had none; while in 3 they were from 1 to 1¼ lines high, or as large as in pregnant women. One of them, a woman 53 years of age, who had long ceased to menstruate, had moderately large papillæ.

Of 4 married women, between 22 and 24 years of age, who had never been pregnant, all had papillæ. One married woman, 53 years of age, who had ceased to menstruate, had no papillæ, but the breasts were atrophied. Thus in only 13 per cent. of these 60 cases were papillæ absent.

Of 334 pregnant women, papillæ were absent in 26 cases, or in about 8 per cent. Of 56 women who had borne children, but were no longer pregnant, the results of examination were as follows:

In all but 3 of 15 primiparæ, who had children under one year of age, the papillary bodies were present, and of varying size.

Of 27 primiparæ and multiparæ, who were still menstruating, and whose youngest children were from 1 to 20 years of age, but 4 were without papillæ, and in two of them the breasts were atrophied.

Of the remaining 14, who had ceased to menstruate, and were between 50 and 70 years of age, their youngest children being from 15 to 35, 11 had papillæ and 3 had none.

Dr. Vedeler accordingly believes that the papillæ of themselves have no value as a sign of pregnancy, since they are found in the menstruating and non-menstruating girl, as well as in the married (sterile, or fecund) woman, or even in decrepid age. They may, he believes, be of diagnostic value, where previously existing papillæ become hypertrophied, or where new ones appear. They may disappear entirely, but under what circumstances is not clear.—*Norsk. Mag. f. Læg.*, 9, 1875.

Uterine Asthma.—Dr. J. Waring-Curran thinks that the treatment of this disorder should be wholly directed towards the uterus. If the asthma precede the catamenia, the latter must be encouraged by a warm bath, while small doses of ergot are to be administered internally. Should the discharge be excessive, it must be controlled but not stopped by the same drug.

The remedy, however, which will relieve the asthma at any stage, is belladonna, applied locally and given freely internally. The extract is the most reliable for external use, and the tincture for internal, and they should be combined with full doses of the bromide of potassium. In the intervals he prescribes iron and strychnine, and applies iodine locally.

He also recommends that the extract of belladonna, spread on a piece of lint, be applied along the lower dorsal and lumbar vertebræ.—*The Practitioner*, Dec., 1875.

Varicella Prurigo.—Dr. Jonathan Hutchinson states that it is probable these cases do commence in children as *bonâ-fide* varicella. Their peculiarity consists in that the eruption, instead of disappearing in a few days, is prolonged indefinitely, by a succession of fresh crops, and that the spots ulcerate and scab, sometimes becoming large sores. He does not think that after the first stage any vesicles appear that are likely to be mistaken for those of varicella. On parts where the skin is thin, these vesicles are like those of pemphigus, becoming turbid very quickly, and are soon broken by the patient's scratching. On the palms of the hands and the soles of the feet perfectly transparent vesicles are not uncommonly found, which last for a few days. The eruption is attended with intense itching. He observes that all the cases he has met with were sporadic. He has never seen persistent vesicular rash following varicella as an epidemic malady.—*British Medical Journal*, November 20th, 1875.

Extirpation of the Uterus by Abdominal Section.—Dr. James R. Chadwick describes the removal of a fibroid tumor of the uterus, extending two inches above the navel and resting below upon the brim of the pelvis. The patient being under the influence of ether, the following operation was performed:

An incision eight inches long was made in the median line, and the enlarged uterus, which was entirely free from adhesions, was lifted out from the abdominal cavity. A Wells' clamp was then affixed to the cervix and broad ligaments, and in addition a double whip-cord ligature was passed through the cervix so as to include the broad ligaments. The body of the uterus containing the fibroid was then cut away, the wound closed with silk sutures, and the usual support of cotton-wool applied. The patient passed through the usual stages towards a recovery, till midnight of the seventh day, when tetanus set in. She lingered, with slight benefit from chloral enemata, and died near the end of the eighth day. The perfect success of the operation *per se* was indicated by the condition found at the autopsy. He is decidedly of the opinion of Péan, who after operating in 20 cases with 15 recoveries, asserts that the danger is no greater than in ovariotomy.—*Boston Medical and Surgical Journal*, November 4, 1875.

Strapping the Breasts to Prevent and Arrest Lactation.—Dr. W. W. Munson has adopted this plan successfully in a large number of cases. He usually commences by placing a strap laterally beneath the breast, half way between the nipple and the lower margin, so as to draw the gland well up, attaching one end of the plaster high up on the sternum and the other end high up under the arm. The next strap is placed at right angles to the first, close to the nipple. Holes are to be cut through the straps that pass over the nipple, letting it project through, thus allowing the milk, which may ooze out, to escape.—*New York Medical Journal*, November, 1875.

The Kansas City Medical Journal has ceased to be published.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

STATE MEDICINE IN ITS RELATIONS TO INSANITY.

ONE of the most interesting and valuable papers presented at the meeting of the American Social Science Association, held at Detroit last May, was that bearing the above title, presented by Dr. Nathan Allen, State Commissioner of Lunacy for Massachusetts, the able writer on insanity and kindred topics. After the compliment this paper has received by its publication in full in the English *Journal of Psychological Medicine and Mental Pathology*, of Oct. 1st, 1875, edited by Forbes Winslow, M.D., with highly commendatory remarks by Dr. Winslow, it needs no further remarks respecting its high scientific value. There are a few points of interest in it, however, which we desire to notice. After giving a full account of what is being done in the different New England States, for the insane, Dr. Allen speaks of the apparent increase of insanity in these States, which he attributes in part to the undue development of brain and a morbid state of the nervous system. He then speaks of the chronic insane, advocating the separation of the acute and chronic cases. The subject of the committal of the insane is ably handled; Dr. Allen's opinion being that improved legislation is needed in most of the New England States, which would throw greater safeguards around the committal of all persons who are charged with insanity. He also very properly speaks of the great importance of a commission of lunacy in each State, and thinks that there should be a more thorough investigation into the etiology of insanity. We agree with him here most heartily, as this subject is altogether too much neglected. The more we know of the causes of insanity, the better able we shall be to strike at the root of the disease, so as to prevent and check it. Dr. Allen very truly says that the public need to understand more clearly the *causes* of insanity, and also to appreciate the fact that these causes are subject in a great measure to the control of human agency. Speaking of legislation in this direction, Dr. Allen remarks: "Nowhere in the whole domain of legislation do we want greater intelligence and liberality, or sounder wisdom and a higher tone of morality than in making the best possible provisions for the insane. There should be combined with such legislation a thorough knowledge of sanitary and hygienic agencies in their application not only to public institutions, but to the community at large, so that the means of *prevention* as well as cure may be wisely employed. And until such legislation takes place no legislators can be said to have discharged their whole duty to their constituents or to the public." Dr. Allen quotes in this connection from the last report of the Commissioners of Lunacy for Scotland, which it will be seen bears directly upon this topic: "It is impossible to come to any other opinion than that insanity is, to a large extent, a preventable malady; and it appears to us that it is in the direction of preventing its occurrence, and not through the creation of institutions for its treatment, that any sensible diminution can be effected in its amount. Lunacy is always attended with some bodily defect or disorder, of which it may be regarded as one of the expressions or symptoms. We must, therefore, attempt to prevent its occurrence in the same way as we attempt to prevent the occurrence of what are called ordinary bodily diseases; and if it be admitted that, to a large extent, preventable diseases exist among us in consequence of the ignorance of the people, it is clear that we can only convert the preventable into prevented by the removal of that ignorance through a sounder education." This idea that insanity is to be prevented by the better education of the ignorant masses, so that they may become proper guardians of their own physical, intellectual, and moral health, is a very sound one, and worthy of the earnest attention and study of all those interested in the prevention and cure of insanity. The subject of the improved treatment of the insane is referred to, and in this connection Dr. Allen introduces two letters, one from Dr. H. B. Wilbur, of the New York Asylum for Idiots at Syracuse, and the other from Dr. Charles F. Folsom, secretary of the Mass. Board of Health and Medical Superintendent of the McLean Asylum at Somerville, Mass., on the improved treatment of the insane in foreign asylums. Both of these gentlemen, with excellent facilities for judging, unite in their testimony of the great amount of good which is being accomplished by the introduction of more liberty and freedom, and more employment, in the asylums of England and Scotland. These asylums have very wisely introduced industrial occupations to a far greater extent than we have as yet in our American institutions, and with the best results. The writer has always held that industrial pursuits of a light nature are an effective and valuable remedy in the treatment and restoration of the insane, and in urging

the adoption of such measures by the State Board of Charities, at the meeting of the American Social Science Association in Detroit last May, gave it, as his opinion, that the system of false economy which refuses to make the necessary outlay for fitting up workshops and engaging the necessary extra attendants for them, results oftentimes (especially in the winter, when out-of-door work is impossible), in the enforced idleness which is too often fatal to recovery.

In Dr. Wilbur's letter mention is made of his visit to the Fife and Kinross District Lunatic Asylum in Scotland, the medical superintendent of which is the able Dr. John Fraser. Dr. Arthur Mitchell, Commissioner in Lunacy for Scotland, had just made a visit to this asylum, and Dr. Wilbur copied a portion of his record upon their register. It shows very forcibly to what an extent the idea of freedom is carried out in this institution. It is as follows: "In visiting the male side of the asylum every door was found unlocked. On the female side, only three doors required to be opened by a key. Of the 245 patients in the asylum, 220 occupied unlocked rooms. This fact involves more than the mere removal or abatement of the sense of imprisonment. It has this desirable result in all the inmates; but to a very large and increasing number it means actual freedom to come and go at pleasure. It is admittedly of importance to avoid the mere appearance of restraint, but much more than this is done here—the freedom accorded to the patients being real as well as seeming. On the male side, in so far as locked doors are concerned, no difference was seen between the arrangements of this asylum and those of an hospital for the treatment of ordinary diseases. It is satisfactory to be able to add, that the effects in the management are to render it easier and cheaper." Dr. Folsom refers in his letter, already spoken of, to his visit to the West Riding Lunatic Asylum, in England, where, of the fourteen hundred patients, not one was undergoing mechanical restraint in any form, and not one was in seclusion. Unlocked doors, a great amount of general freedom and occupation, and a large number on parole, he speaks of as being the prevailing and noticeable features of both this and Dr. Fraser's Scotch asylum.

This bold advancement in the treatment of insanity, originating in the Scotch asylum, with Dr. Batty Tuke, the former superintendent, based on the principle that insane patients will appreciate and justify the trust that is reposed in them, has proved eminently successful in England and Scotland, and we hope the day is not far distant when we may successfully emulate them.

It is but due to our own institutions to state, that owing to the management of our American asylums, the medical superintendent is generally unable to employ as many attendants as would be requisite for the successful establishment of such a mode of treatment in our asylums, owing to a false system of economy respecting the care of the insane, adopted by many boards of charities in the United States. To do this successfully, we should require not less than one attendant for every eight patients, and *well-trained* attendants also. This would double the number now employed in most of our public institutions. There is one point, however, where we think the English and Scotch asylums might copy us with advantage, and their costly hospitals would thereby become much more useful curative institutions than they are at present. We refer to our comparatively recent experiments in New York, Rhode Island, and Massachusetts, of asylums for the chronic and incurable insane, which are regarded by the highest authorities as valuable auxiliaries to our present mode of treatment, as they ease our hospitals of the dead weight of chronic insanity which fill our halls and impede us in our efforts toward the cure of recent and acute cases.

It has been stated by competent authority that fully ninety per cent. of the inmates of these fine European asylums are chronic, incurable cases, on whom all this expenditure for elaborate organization and classification is thrown away.

What such patients want is, a good *asylum* and *home*, not a *hospital*, which latter they only cumber up, to the great detriment of the recent, curable cases.

In Great Britain, the chronic insane have been sent to their friends or drafted to workhouses, both of which methods of disposing of them are obviously improper, as this class need competent medical supervision no less than recent insanity. The Twenty-Ninth Annual Report of the Commissioners in Lunacy for England and Wales shows that there are 10,000 lunatics in workhouses, and in their report they notice and acknowledge the fact that the hospitals for the insane are becoming filled up more and more with incurables. We do not intend these remarks as a criticism on Dr. Allen's paper, but merely to draw attention to the fact, that while there are many improved methods of treatment in foreign asylums which we should doubtless do well to imitate, yet we are much in advance of them in this respect at least, which we shall do wisely, we think, in following up, by erecting in every State an asylum for the chronic insane. Without saying more upon this subject, we would in closing congratulate Dr. Allen for his very valuable contribution to the literature of insanity, which he has made in his paper on "State Medicine in its Relations to Insanity."

MEDICAL STAFF RANK.

THERE is no doubt that an attempt will be made in the House to reduce the army about one third. While it seems probable that this attempt will not succeed, it may serve as an excuse for delaying action upon the legislation asked in behalf of the medical department.

It will be remembered that during the last Congress

petitions from almost every Medical Society in the United States were forwarded to that body requesting the passage of a bill, recommended by the American Medical Association, to make the position of the medical officers equal to that of the other staff corps. The House Committee on Military Affairs agreed without a dissenting voice to report this bill to the House, and one of its members was charged with this duty. This gentleman, although professing the greatest good will towards the medical department, and to this bill, never reported it, although he found opportunity to report and to get passed several bills for the benefit of other staff corps. By this ingenious specimen of what is known among politicians as "management," he prevented the bill from coming before the House at all. The American Medical Association at its last meeting appointed a new committee to bring the matter again before Congress. It is understood that this committee have decided to present it first to the Senate, which contains more of its previous members than the House, and is therefore more familiar with the subject. The chairman of the Military Committee of the Senate, General Logan, has promised, as we understand, to prepare and introduce a bill which will at least give some relief.

Precisely what form this bill will take has not been decided, but it is supposed that it may give to the medical department six colonels and twelve lieutenant-colonels.

HOMŒOPATHY IN MICHIGAN UNIVERSITY.

It will be remembered that in a recent number we made this remark:

"In answer to an inquiry by some of the students of the Medical Department of the Michigan University, Prof. Palmer is reported to have said in substance: 'With Dr. Sager it was a question of only two hundred dollars, while with us (the Faculty) it was a question of eighteen hundred dollars.' If there is any real foundation for this assertion it would appear that the matter of principle is not the only one which has actuated the said faculty in the stand which they have taken. We sincerely hope that some reasonable excuse can be offered for lowering the dignity of the position assumed to the meanness of a pecuniary consideration."

In a subsequent number it will be recollected that Prof. Palmer emphatically denied the charge. Since then we have communicated with our informant, and find that he had no foundation whatever for the statement he made to us. We always strive to obtain our information on good authority, but in the present instance we have been in error, and willingly acknowledge the fact. If our readers were acquainted with all the circumstances connected with this information, as we now are, they would not think it strange that we had been misled. However, we were careful enough to say at the outset that the statement was founded on a rumor.

RELATIONS OF PHYSICIANS AND DRUGGISTS.

In another column will be found a communication from a gentleman who speaks in defence of the objectionable practices of druggists. The arguments which he offers are quite original, if not convincing. The plea for "counter prescribing" is perhaps the most absurd of any that has been thus far advanced. No one, it is true, has a right to prevent any free-born citizen from chosing his prescriber, provided the object of his choice be competent. But if, despite the pretension, the latter qualification is not possessed, who shall take the responsibility of an occasional blunder? We must, however, for the sake of the argument, allow the latter to be impossible.

MEDICAL STUDENTS' RECEPTION.

The Young Men's Christian Association gave a reception to the medical students of the different medical colleges on Tuesday evening last. We are happy to say that the affair was in every way a success, and the guests fully appreciated the efforts made for their entertainment. The addresses delivered by Professors Fordyce Barker, T. Gaillard Thomas, and D. B. St. John Roosa were exceedingly appropriate and were well received. Altogether the students were made to feel their welcome, and no doubt carried away the impression that a sympathetic interest existed, not only towards them, but to the profession of which they are the prospective members. These gatherings do good in many ways, and should be encouraged by all interested in the rising generation of medical men. The Association, and particularly the committee who had the matter in charge, deserve the thanks of all for a very enjoyable and profitable evening to their guests.

Patients' Notions of the Clinical Thermometer.—A recent number of the *Student's Journal* gives some amusing examples of the "hazy" notions that illiterate patients in a London hospital had of the nature and uses of the clinical thermometer. A young woman who was convalescent, and whose temperature had long remained normal, had a slight relapse, which she attributed to having had "no glass under her arm for a week." A man suffering from acute rheumatism obstinately refused to have his temperature taken any more, saying "it took too much out of him. It was a drawing all his strength away." A man had been in the habit for some time of having his temperature taken daily under his tongue, with a thermometer that had just been doing severe duty in the axillæ of other patients. One night a brand-new thermometer was applied to his mouth, next day he declared he was not so well, and said "the glass was not so strong as usual; he felt at the time the taste was different, and it had not done him so much good!" A Sister in one of the women's wards says that many of the patients think the thermometers are used to detect breaches of the rule against having unauthorized edibles brought in by friends; and she accordingly does not disabuse their minds of their innocent superstition.

Reviews and Notices of Books.

THE POPULAR HEALTH ALMANAC FOR 1876. Edited by Frederick Hoffman. New York: E. Steiger, 22 and 24 Frankfort St. 8vo, pp. 44 (pamphlet).

THIS very useful and instructive annual is published with the ostensible purpose of replacing the various almanacs which are so plentifully distributed to the public by the nostrum venders. It is hoped that this means to counteract, in a measure, the schemes of the countless numbers of patent-medicine humbugs, who use an almanac for the purpose of advertising their dangerous wares. We doubt not that so far the almanac before us will fulfil the design of its editor, and be at once creditable to the giver, while at the same time it is instructive to the public. Its modest aim is to furnish useful information on matters of health, advice in emergencies, and the exposure of fraud connected with the patent-medicine trade, at the same time preserving all the features of a first-class almanac. In all these particulars it is so much a model of its sort that it meets with our unqualified approval.

A TEXT BOOK ON HUMAN PHYSIOLOGY, designed for the use of Practitioners and Students of Medicine. By AUSTIN FLINT, Jr., M.D., Professor of Physiology and Physiological Anatomy, Bellevue Hospital Medical College, etc. New York: D. Appleton & Co. 1876. 8vo, pp. 947.

THIS work is principally an abridged compilation of the five volumes of the author, for the sake of adapting the same to the uses of the student. Even with the greatest care in the condensation, the volume is of a ponderous, almost of an unwieldy size. Several new illustrations have been added with the view of lightening the labors of the students, although very little of entirely new material is presented. The chapter on the blood has been entirely rewritten, and there is an account of the depressor nerve which is not found in the larger volumes. As a work for students it will doubtless be of value, although a much smaller one would, for obvious reasons, be more acceptable. To the general practitioner, who cares to master the subject more in detail, the work will be especially useful.

ILLUSTRATIONS OF CLINICAL SURGERY (Fasciculus I.). By JONATHAN HUTCHINSON, F.R.C.S., Senior Surgeon to the London Hospital, etc. Philadelphia: Lindsay & Blackston.

ATLAS OF SKIN DISEASES (Part I.). By TILBURY FOX, M.D., F.R.C.P., Physician to the Department for Skin Diseases, in University College Hospital. Philadelphia: Lindsay & Blakiston.

THE illustrations by Hutchinson are to consist of plates, photographs, woodcuts, diagrams, etc., reproduced from a large collection, formed by the author during his professional life. The first fasciculus embraces four folio plates, including one colored and two plain lithographs of *encephalocele*, one plain lithograph of *ivory exostosis of the orbit*, three life-size chromos of *rodent ulcer*, and three chromos illustrating *chancre*. In addition there are a number of woodcuts. The artistic execution is all that is to be desired, and there can be no doubt that they will prove of service in facilitating the recognition of some of the rarer forms of external disease. Of their value in this connection the author relates, that upon one occasion he was called upon to examine a frontal tumor, into which a surgeon was about to introduce needles, in the belief that it was a vascular nævus. The fact that our author had previously seen a photograph of a case of encephalocele, enabled him to recognize the true nature of the growth, and to prevent an operation which would doubtless have proved fatal.

The value of well-executed illustrations as "royal roads to learning" cannot be estimated too highly. The publishers intend to issue additional fasciculi at intervals of three months.

FOX'S atlas purports to be a reproduction of Willan & Bateman's "delineations," to which will be added a number of new subjects. The first part contains four colored plates, illustrating five varieties of erythema, and two of urticaria. Comparing them with the edition of Bateman (1817) we find that the artist has taken little more than the idea of the original, which he has elaborated into much more truthful and life-like representations of the diseases portrayed.

While these plates are not equal to the magnificent cutaneous portraits by the late Dr. Elfinger, they will, doubtless, in consequence of their lower cost, obtain a wider circulation, and prove of great value to those who have not extensive clinical opportunities for studying this class of diseases. Additional parts will be published monthly.

Correspondence.

THE BLOOD-CORPUSCLES IN SYPHILIS.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—In the report of my remarks on Dr. Keyes's interesting paper in your issue of January 8th, I am made to say that it is the accumulation of white blood-cells which constitutes one of the manifestations of syphilis.

What I did say was, that the accumulation of *vitiated*—that is to say *imperfect* cells (which could not be distinguished under the microscope from the normal white blood-corpuscles) constituted the material of *every* known manifestation of syphilis. That chancrous indurations, syphilitic gland enlargements, syphilitic papules and tubercles, gummy tumors, etc., were all made up of these *vitiated* white blood-corpuscles; and that the evidence of their vitiation or imperfection was in the fact that such accumulated corpuscles were never able in any instance to enter into the composition of any useful tissue, but were only present as an obstruction to the healthy action of the vessels and tissues with which they were in contact—*and hence* the elimination of this *imperfect* material, was the direct object of treatment; that mercury, which was known to be an active agent in bringing about the fatty degeneration of *healthy* tissues, might be readily accepted as capable of effecting the same result more easily and promptly in the case of the imperfect material; that chemical experience had shown *this* to be the fact, inasmuch as the moderate and prolonged use of mercurials has been found to be more efficacious in the cure of syphilis, and less harmful to the general system of the patient than where it was pushed to salivation, as was formerly considered essential, *and hence* we were led intelligently to the treatment of syphilis by a mild and prolonged mercurial course, rather than to the adoption of the

empirical method of administering the drug as an *antidote* to syphilis. The inference was then drawn that all forms of treatment which favored fatty degeneration and elimination might be expected to be useful in the treatment of this disease, and that the facts stated by Dr. Keyes were important as furnishing an additional aid in ascertaining the effects of treatment.

Very truly yours,

F. N. Otis.

108 W. 24th Street.

THE TREATMENT OF TYPHOID FEVER.

A LETTER FROM THE LATE SURGEON GENERAL TO THE EGYPTIAN ARMY.

To the Editor of The Medical Record.

Sir:—I have read with great interest Professor W. H. Thomson's lectures on the treatment of typhoid fever. They are admirably conceived, and they embody an amount of practical sense and scientific knowledge which reflects great credit upon their author. With your permission, however, I will supplement them with some observations which have been gathered from rather an extensive experience of my own in the same field.

There is undoubtedly a strong disposition at present to run away with *pyrexia*—to confound it with the disease of which it is a symptom, and to regard its arrest or abatement as the only indication worthy the consideration of the physician. To many minds there is no danger to be feared, save that which the *thermometer* signals and illustrates; and no remedies to be evoked, except such as *cold water* supplies or typifies. In a word, the views which the "German School" has promulgated relative to the disastrous influences exerted upon the organism by an elevated temperature, have been so enthusiastically adopted by the profession as to obscure the true pathology of typhoid fever, and to inspire a blind subserviency to the therapeutical dogmas recorded by Ziemssen *et id genus omne*.

Without entering into any formal argument to demonstrate the fallacy of these ultra ideas, I will simply oppose to them a few practical statements, respecting the reliability and the logic of which there can be no discussion.

1. Peyer's patches sometimes ulcerate even to the point of intestinal perforation, without the concomitant occurrence of any special elevation of temperature to indicate the existence of a typhoid infection.

2. The degree of heat developed in typhoid fever, and the virulence of the disease itself, do not sustain a necessary and invariable relation.

3. Patients constantly succumb after the temperature has reduced itself, or has been reduced by remedies, within what are esteemed the boundaries of security.

However important it may be in certain cases to subdue the *pyrexia*, the indication which presents itself in this respect should be met intelligently and guardedly. The physician should remember that the *heat*, with which he has to deal, is *not really the disease* to be combated, and that the remedies demanded are "heroic," and require the nicest discrimination in their employment. He should distinctly realize that, in laboring to reduce the temperature, he is only attacking *one* of the obstacles which interfere with the operation or exhaust the energy of that "principle of conservation" which the system requires, in order that it may be carried safely through the trying ordeal of the typhoid infection. And he should most rigidly guard against that fallacious infatuation which satisfies itself with a crusade against *pyrexia*, whilst it ignores the paramount obligations to strengthen the failing powers, to renew the wasting tissues, to utilize the hampered digestive processes, to limit the disastrous ulcerative action, to eliminate the contaminating products of the crude and unhealthy metamorphosis, and to assail *every* symptom which, by obstructing functions, or developing complications, or combining with essential phenomena, adds to the patient's discomfort or diminishes his chances of recovery.

As I have before indicated, *antipyretics* are powerful alike for good and for evil. They are, in fact, like the knife of the surgeon, which threatens disaster in one direction, while it heralds relief to another, and becomes a weapon of death instead of an instrument of mercy, by the slightest error of judgment or deficiency in dexterity. The gravest problem, perhaps, in the whole range of practical medicine is that embodied in the question of *when* and *how* to employ this "energetic" class of agents. Take *external cold*, for instance—the pet hobby of modern therapy. Whilst according to it all the efficacy as a "heat reducer," which the most ardent advocate can claim, who can estimate the dangers attendant upon its employment in typhoid fever, when the heat is especially feeble or the lungs are profoundly congested, or the skin is morbidly sensitive, or the kidneys are engorged and desquamative, or a constant tendency to collapse manifests itself *ab initio*? The lesson to be learned from its wonderful effects in pyretic conditions must be studied in conjunction with that which is taught likewise by the facts, that the morbid condition immediately preceding death by cold is one of *prostration*, and that the pathological phenomena immediately following such a result are an *accumulation of blood* in the right side of the heart and *congestions* of the viscera generally. The same may be predicated of *baths at a low temperature*, with the supplementary statement that the mechanical pressure of the water upon the surface of the patient, which is about one pound to the square inch, and the effects of the movements and manipulations incident to the process of bathing, are to be duly considered in estimating their advantages and their disadvantages as remedial agents. I know well that it will be regarded as rank rebellion against scientific progress to question in the slightest degree the efficacy of cold baths in the treatment of typhoid fever; and yet I feel constrained to say, that in my judgment, although they do possess great value as remedial agents when circumstances really justify their employment—as the abated sufferings and rescued life of many a patient emphatically attest—they are sometimes barren of results, often positively injurious, and generally used with little judgment or discrimination. Without recapitulating what has been said already respecting the dangers incident to an exclusive or an ill-considered antipyretic treatment, or dwelling upon the first of the supplementary statements offered above, I will say a single word touching the *second* observation made in that connection. In a considerable percentage of typhoid patients the tendency is *to syncope*, and death occurs from *asthenia*. A position of absolute recumbency and a condition of perfect repose become, therefore, essential elements in the treatment of such cases. When a life is trembling in the balance of an enervated and struggling heart, the slightest movement or exertion is fraught with peril, and may prove fatal. I would, therefore, lay it down as a cardinal rule of practice to except this class of patients—*ie.*, those in whom cardiac weakness, however it may be developed, is a conspicuous symptom—from the treatment by cold-water baths, because assured that they are prolific of disaster under such circumstances.

When *cold* is demanded and baths are contraindicated, the *pack* is usually resorted to, though from the rapidity with which heat is evolved, it is often difficult to keep up a proper temperature for more than a very brief period. *Ice applied to the spine* by means of *Chapman's bags* is an admirable substitute for the cold-bath, and a far more convenient and reliable means of reducing the temperature than the pack. No appreciable decline takes place after its removal, while the impression produced can be prolonged at discretion—two most important considerations in estimating its value as an antipyretic agent. *Injections of cold water into the rectum*, at frequent intervals, sometimes act wonderfully well. As a general rule, I have not found the diarrhœa increased by them, while I have repeatedly seen dysenteric symptoms subside under their employment. My father, who was an ardent disciple of Broussais, treated typhoid fever habitually and very successfully with injections of cold water, to which the tincture of opium was added in sufficient quantity to restrain the bowels; supplemented by a liberal supply of powdered ice, and of milk with lime water by the mouth; frequent dry cuppings over the abdomen and spine, and cold applied continuously to the shaven scalp by means of bladders filled with ice or iced water. This mode of treatment—I mean the cold-water injection plan—has just been revived by Dr. Folts, who has published a series of valuable papers in the *Lyon Médicale*, giving his observations and experience on the subject. He states that they exert a *local* and a *general* action. The *local action* consists in a cooling sensation, accompanied by intestinal contractions; while the *general action* is illustrated by slackening of the pulse, marked diminution of temperature, abatement of thirst, augmentation of secretion, and quietude of the nervous system. In his judgment they constitute the most valuable remedy in typhoid fever yet known to the profession; and after a long experience, I am prepared also to indorse them in a very emphatic manner.

Injections of iced water under the skin, also, answer admirably when the pyrexia is especially prominent and persistent. They not only reduce the heat, but control in a marked degree many other important symptoms. An ounce of ice water can be injected daily, by dividing it in two portions, and distributing them over different parts of the body. When *quinine* is not well borne by the stomach, or the patient refuses it, advantage may be taken of these injections to introduce it into the system; and they can, likewise, be made vehicles for the administration of *peptones*, which, according to the demonstrations of Stricker and Oser can be thus absorbed without difficulty. Diluted milk may be cooled down and injected in a similar manner, to act as an antipyretic and to serve as a *nutriment* as well, since Menzel and Pero have shown that nutrition can be effected in this way, while Kreugg has not only confirmed their experiments, but proved that other nutritious matters can be administered hypodermically with equal advantage and a like impunity. While referring to hypodermic injections, permit me to say, that I first injected *brandy* under the skin in the early part of the year 1867, as the *Baltimore Medical Bulletin* will show, and that I have continued so to employ it, in extreme cases, up to the present moment. Can you tell me whether or not it had been administered subcutaneously prior to that date?

Quinine is, unquestionably, a valuable agent in the treatment of typhoid fever, both from its anti-periodic and its febrifuge properties. Malaria plays a far more important *rôle* in the clinical history of this disease than is generally supposed. As it is almost impossible to find any one who has not been at *some period exposed* to the subtle influences of this peculiar poison, so is it equally difficult to meet with an affection—especially a *fever*—over the phenomena of which it does not exercise *some* control. Independent of those instances in which the regular occurrence of exacerbations constitutes a prominent feature, there are multitudes of others to which it adds an incident or a complication, whereby the infection is intensified or the system rendered less capable of resistance. As a general rule, therefore, *quinine* is indicated in typhoid fever, on account of its *antiperiodic* properties, as the agent by which the malarial incident or complication can be most readily removed. The well-known *antipyretic* properties of this drug render it an important adjunct in the treatment of typhoid fever. It should not, however, be administered too liberally—not according to the demands of enthusiasm, but to the dictates of experience. If it be administered in "heroic doses" or very frequently, it overdoes the work required of it, and produces a *cinchonism* which adds to the burdens of the already struggling system, whilst it increases the derangement of the nervous centres and intensifies the disturbance of the digestive function. Doses of from *ten* grains to *fifteen* grains, three times daily, answer better than those of larger quantities more rapidly exhibited. Quinine should be given with especial caution when the *pulse* is *hyperdicrotous* or after *conception* has *occurred*, since it exerts a *sedative* influence upon the heart and a *stimulating* action upon the uterus in a very marked degree. I have sometimes seen the febrifuge properties of quinine decidedly increased by the addition to each dose of the quarter or the sixth of a grain of morphia and two drachms of the sulphate of magnesia, with water enough to dissolve them properly—say one ounce and a half.

Calomel is a good remedy, but it should never be employed, according to my experience, after the seventh day. I have repeatedly seen intestinal perforation follow its administration in the advanced stages of the disease. As a general rule, it is better borne and should be more freely given, when meningeal, hepatic and malarial complications connect themselves with the febrile attack.

Inunction is valuable in all diseases which are characterized by a hot, harsh and dry skin, and especially so in typhoid fever. By restoring the functions of the sebaceous and the perspiratory glands, and relieving the irritability and the tension of the cutaneous surface, it assists in removing effete matters from the blood, and indirectly stimulates the other organs to an abandonment of their torpidity. In a word, it re-establishes the normal equilibrium and legitimate relation between the integument and the viscera, and transforms the *fons et origo* of an infinite variety of morbid reflex actions into a source of healthful impulses and of physiological sympathies. The *reduction* of heat which follows oleaginous inunction in typhoid fever settles the question in regard to the absorption of fatty materials by the skin, and demonstrates the reliability of the views of Bernard and Walkenstein in that regard, since, if carbo-hydrogenous elements did find their way into the system under such circumstances, increased combustion, with a consequent *elevation of temperature*, would be the natural consequence.

I am convinced that *warm poultices* do more harm than good in this disease. While they are agreeable to the patient and *convenient* to his attendant, they really increase the heat and concentrate it upon that portion of the body which is the special seat of morbid action. They are prolific sources, in truth, of meteorism, hemorrhage, diarrhœa, and intestinal perfora-

tion. Cold, applied by means of flannels saturated with iced water or bladders filled with ice, should be employed in their stead. Space will not permit me to say what I had proposed in regard to *turpentine*, but I cannot conclude without putting in a word for it. Although by no means a "specific," nor of universal applicability, yet, as a general stimulant to the system, and a special excitor of the secerning organs—particularly the skin and kidneys—it has scarcely a superior in the Materia Medica. In the later stages of the disease, when the tongue is specially dry and cracked, the abdomen unusually tympanitic and tender, the skin excessively dry and harsh, the kidneys decidedly insensible and torpid, the pulse thready and *monocrotous*, it frequently acts like a charm, not *curing* the disease, of course, but giving to the crowded system "a fairer field and a fuller opportunity for resistance."

Alcoholic stimulants, as a general rule, are not required, since they increase combustion and develop pyrexia. When it is necessary to resort to them, as in threatened collapse, or when the pulse and temperature are apparently in contradiction—the one being excessively frequent while the other is not excessively high and *vice versâ*—or after hemorrhage or in conjunction with exhaustive diarrhœa, etc., etc., "dry" *champagne*, either completely frozen or ice cold, should be selected. Fortunately for humanity, the chimeras of Todd and kindred "alcoholists" have had their day, and brandy is no longer the panacea which enthusiasts "swear by." At best this "plan of stimulation" was like holding a candle out of a window and mistaking the coruscations of an accelerated combustion for the indices of an increased intensity and duration of illuminating power. Patients got *better*, or seemed to, but they *died in the end*, a little faster and more certainly than before.

Sulphate of copper is the best remedy I know of for the diarrhœa of typhoid fever. Half a grain should be administered every second or third hour, combined with very small quantities of morphia or opium, and associated appropriately with camphor, copaiba, cubebs, turpentine, or creosote. This drug seems to exert some special curative influence over the ulcerative action which takes place in the intestinal glands. Sometimes typhoid fever associates itself in a very striking manner with epidemic erysipelas, and, when such a relation exists, the *mineral acids*, or *the hyposulphite of soda*, or the *muriated tincture of iron* can be used to great advantage. The fact of this association, and the beneficial action of these remedies, with other circumstances, has tempted me to regard many a so-called case of typhoid fever as a veritable erysipelas of the glands of the small intestines.

With reference to *nourishment*, I would most heartily endorse all that has been said in favor of milk as an article of diet. Like cod-liver oil in certain cases, it is both a *medicine* and a *food* in typhoid fever. It should, however, *generally be skimmed*, and *never sweetened*, since oleaginous and saccharine elements are *calorifacients*, whilst a certain amount of lime water should be combined with it, unless an acid treatment be decided upon. Occasionally, however, milk disagrees with the patient, and becomes a source of disturbance instead of support, and the physician should remember this fact, and be prepared to meet it promptly. I am convinced that *solid food* is often a desideratum, and that great advantage results in many cases from the employment of *raw meat*. By giving *pepsine*, or, better still, *pancreatine*, especially when tympanitis is very prominent, its digestion is secured, and nutrition is correspondingly reinforced.

There is one remedy, as yet but little known, which is destined to a conspicuous career in the therapy of typhoid fever. The *monobromide of camphor* not only possesses the medicinal virtues of the bromide family and of camphor in a happy combination, but is preeminently *antipyretic* in its action upon the economy. M. Bourneville, after many careful experiments, has demonstrated that the monobromide of camphor lowers the temperature *rapidly and decidedly*, whilst it lessens the frequency of the pulse, diminishes the number of inspirations, and abates nervous excitement, without disturbing the digestive functions. These conclusions have been thoroughly verified by the observations of M. Pothault, who declares that he has reduced the temperature of inferior animals as much as 3° C. in an hour, and found that the subsequent process of heat evolution is unprecedentedly gradual and protracted. From these statements it will be at once perceived that this drug possesses precisely those remedial elements which are most required in the treatment of typhoid fever, and that its introduction is an invaluable acquisition to modern materia medica. Having recently administered it with admirable results, it gives me pleasure to suggest its employment to my confrères. The dose of the bromide of camphor is from *three* to *ten* grains, repeated every third hour until a decided impression has been made upon the temperature or the circulation.

The best *hypnotics* are either *chloral* or the *bromide of potassium*, in combination with *codeia* and the *tincture of sumbul*, according to the following formulæ:

℞. Chloralis hydratis..... ℈ij.
Codeiæ..... gr. i.
Sumbul. tincturæ..... ♏ iij.
Aurantii syrupi..... f ℥ ss.
Aquæ cinnamomi.....q. s. ad f ℥ iij.

M.—S. One-half at a dose, and the remainder in three hours, if necessary; or,

℞. Potassii bromidi..... ℈ i.
Codeiæ..... gr. i.
Sumbul. tincturæ..... ♏ ij.
Aquæ cinnamomi.....q. s. ad f ℥ iij.

M.—S. One-half at a dose, and the remainder in three hours if necessary. The chloral mixture should be given without syrup, if the patient can be induced to take it, for reasons previously explained.

As I have already written so much more than was originally intended, I must reserve my observations on *cardiac* and *arterial sedatives* for another occasion; and, with the hope of pardon for this very crude and protracted communication, I beg to subscribe myself very respectfully your obedient servant,

EDWARD WARREN, M.D.

No. 33 RUE CAUMARTIN, PARIS.

THE RELATIONS OF PHYSICIANS AND DRUGGISTS.

TO THE EDITOR OF THE MEDICAL RECORD.

PHYSICIANS and medical journals seem to delight in "showing up" druggists in anything but a favorable light, and it is time, I think, to put in a word for what may be called the *other side* of the question at issue. Is there a business man who believes that a drug-store devoted exclusively to putting up physicians' prescriptions "would pay"? This is a question that every man entering upon a business must seriously consider, "Will it pay?" Occasionally an attempt has been made to transact a purely retail drug business, but the failures have been so signal, that the attempt has been rarely repeated. Even physicians, who have had much

to say upon this subject, have failed to encourage any such effort, choosing rather to send their prescriptions to those who dealt in Yankee notions, cigars, patent medicines, homœopathic specifics, and soda and saline waters as well as drugs. Whether *percentage* had or has anything to do with the directions of these immaculate doctors, it does not at present become me to say. And now what just objection can be offered against a druggist dealing in miscellaneous articles, so long as this trade does not interfere with the proper filling of prescriptions? I take it that there is no good ground of complaint, and that objections often urged are fancied rather than real. Much complaint is made on the part of some, that druggists keep on hand and deal in homœopathic remedies. I presume it to be true that if these remedies had no sale druggists would not deem it worth while to keep them on hand. But it is useless to ignore the fact, that the number of people who employ homœopathic physicians and remedies is neither small nor, in most matters, greatly lacking in intelligence. And just where lies the great moral turpitude of dealing in what these people want, is not strikingly apparent to an unprejudiced mind. As to the crime of dealing in patent medicines of various kinds, there may be some room for argument. It would, without doubt, be a sweeping statement to say, that they, one and all, are worthless—that they are put up solely with a view to sale, with no regard whatever to their curative virtues. If such were the case, if they had no merits whatever, their sale would probably not be long continued. It may be sufficient to say, that not a few reputable physicians use in their own families and employ in practice—perhaps rather *sub rosa*—patent medicines, of which they know not the ingredients, but which they have confidence in, gained simply from observing the favorable effects following their use. It will be easy to deny this, or to say that such physicians are not reputable, or that in so doing they have broken a solemn obligation, but the fact I have stated can be confirmed upon inquiry at almost any drug-store.

Lastly, druggists are charged with usurping the prerogative of the doctors in *prescribing* for such as ask them to do so. This is a serious charge, and should be carefully examined into. In the first place, who gave M.D.'s an exclusive right to recommend or direct what the sick and ailing may or must take? May a mother or nurse use boneset or anise-seed tea without asking the permission of the learned doctor? May not a friend or neighbor suggest a dose of ipecac or spiced syrup of rhubarb, or a hot bath, without a doctor's license? And when a sufferer from neuralgia or from a racking cough prefers to ask the druggist for a remedy, rather than consult the doctor, it may not be flattering to the doctor's opinion of his exclusive right to prescribe drugs, or it may be evidence of a want of good judgment on the part of the person afflicted; still, I am not aware that any one has a right to restrict him or to dictate to him in the choice of a medical adviser.

It is not my purpose to advocate or to justify indiscriminate prescribing by mere druggists, yet I am inclined to think there are frequently circumstances mitigating what the doctors style a heinous offence.

Some of the doctors who have much to say in relation to this matter send few patients to drug-stores for medicines—are themselves dispensers of pills, powders and liquids from a miniature peripatetic drug-shop, carried about with them in the shape of saddle-bags, or the more recent and fashionable medicine chests and pocket cases. If I observe rightly, this custom of carrying a small stock of medicines, in cities, is rapidly increasing. I am not inclined to condemn the practice in itself, while it is restrained within proper bounds, for I can see that it has many good features to recommend it. But it seems to me that if the right of prescribing *does* belong exclusively to the doctors, the business of dispensing drugs belongs *as* exclusively to the pharmacists.

I presume the mutual relations of the parties to the contest will, after all, in some measure regulate themselves, and my advice to both parties I offer in the slightly amended doggerel:

> "Doctors and druggists, each pursue
> The course that seems the best to you,
> And let the grumblers grumble."

Medical Items and News.

New York Academy of Medicine.—The following officers were elected at a meeting of the New York Academy of Medicine, held January 6, 1876:

For Vice-President—Dr. Fordyce Barker.

For Trustee—Dr. S. T. Hubbard.

Committee on Admissions—Dr. T. M. Cheesman.

Committee on Medical Ethics—Drs. O. White and M. Morris.

Committee on Medical Education—Dr. C. C. Lee.

Committee on Library—Drs. J. H. Hinton, J. R. Leaming, E. D. Hudson, Jr., C. M. Allin, and George Bayles.

Drs. J. W. McLane and H. F. Quackenboss were elected resident Fellows.

Army News.—Smith, R. E., Assistant Surgeon, has been assigned to duty at Fort Bayard, New Mexico.

The Prize Committee, appointed by the Executive Committee of the Alumni Association of the College of Physicians and Surgeons, at their meeting on March 2d, 1875, consists of the following gentlemen: Prof. Henry B. Sands, M.D., Dr. Edward C. Seguin, Dr. Ellsworth Eliot.

As the Register and the college catalogue both give a different list of names, it seems desirable that the correct one should be published.

Miss Isabella G. Clark, having passed the major examination of the Pharmaceutical Society, was admitted as pharmaceutical chemist on the 15th of December. There are several ladies, it is said, on the register as "chemists and druggists," but this is the first instance in Great Britain in which a lady has passed the major examination as pharmaceutical chemist.

Professor Wilhelm Boeck, of Christiania, the well-known syphilographer, whose visit to the United States a few years since made him many friends, died on the 10th of December. His efforts to introduce syphilization as a means of prophylaxis against the disease are well known, but have secured him no followers.

Original Communication.

THE TREATMENT OF SYPHILIS.

BEING A PART OF ONE OF THE ANNUAL REPORTS ON THE PROGRESS OF MEDICINE AND SURGERY * PREPARED FOR THE MEDICAL JOURNAL ASSOCIATION OF THE CITY OF NEW YORK.

By R. W. TAYLOR, M.D.,

PHYSICIAN TO CHARITY HOSPITAL, ETC., ETC.

MR. PRESIDENT AND GENTLEMEN:—It has been my object in preparing this report to treat of subjects most interesting to a Society such as this, composed principally of general practitioners. Thus, its character and scope differ widely from a similar *résumé* prepared exclusively for specialists. Having, according to the wish of the Society, to include articles published since January, 1874, there was on my hands such a mass of material that it would have been impossible in the time allotted to me to have presented them, even in brief; therefore I have selected such of these subjects as to my mind were most interesting to the members; such, indeed, as are most intimately connected with the daily wants and experience of the general practitioner. As the treatment of syphilis is such an important subject, I have devoted considerable space to its review.

Since January, 1874, a number of important articles have appeared on the treatment of syphilis. The greater proportion have been written by believers in the value of mercury, while antimercurial views have been urged by a few. By far the most important paper, by reason of its clearness of diction, solidity of argument, and comprehensiveness, is the one by that careful observer of syphilis, Mr. Jonathan Hutchinson. His paper, "Use of Mercury in Syphilis" (*Lancet* 1874), bears the impress of long and patient research, unattended with prejudice, and it is fair to suppose that it has and will continue to exert an influence salutary in its effect upon the medical world. As a model of clear and calm reasoning and pertinent argument the paper takes high rank. Hutchinson's conclusions are as follows, which are here given very briefly.

Mercury is the vital antidote to syphilis, curing the disease, as shown by cases of subsequent perfect health after a first attack which is followed by a second.

A cure depends upon the stage of development attained by the disease before treatment is instituted. Mercury must be given for a long time in considerable quantities, avoiding salivation, which is injurious. Susceptibility to the agent indicates mild doses.

Give the remedy as soon as indication is noticed, as secondary symptoms will then be very mild if they occur, and they may not.

Mercury is powerful in delaying the second stage, and repeated outbursts indicate that its administration has not been sufficiently active rather than that the agent is inefficacious.

Tertiary lesions appear in proportion as the secondary stage has been long and severe, and are less frequent when mercury is given early.

This drug does not injure the health if given cautiously, and it may be administered even in ulcerative conditions, as it is not contraindicated by any particular form of syphilis. Iodide of potassium is inefficacious in the primary and secondary stages, while mercury acts well where it fails.

The mode of administration is of no great importance, provided toxic effects are avoided. The whole text of this paper is worthy of careful study. I may here remark, that lengthy criticism by me is now inadmissible; but I could suggest that very strong arguments may be brought up against giving mercury quite as early as advised by Hutchinson, for I am disposed to think that the cases are exceptional where this is needed, and that a much better result attends delay until the evolution of secondary symptoms.

Influenced by these arguments, as well as by those of Fournier, of Paris, Dr. C. R. Drysdale, who has long been known as an ardent antimercurialist, has recanted his former doctrines, and now appears in the ranks of mercurialists. In a paper recently read ("On the Antecedents and Treatment of Tertiary Syphilis") this author makes a profession of faith, and manfully acknowledges his conversion. The chief value of his paper is his assertion, that he has seen tertiary lesions follow a non-mercurial treatment. Though this fact is well known, it is important in this connection, as one of the strong tenets of the antimercurial faith is the alleged baneful effect of mercury in producing tertiary lesions, which by many are said to be the result of that drug, and not the manifestations of the disease at all. Apropos of this subject, an article by Van Buren and Keyes ("A Contribution to Syphilidology," *Archives of Dermatology*, Jan., 1875) affords food for thought, as there are in it detailed two cases of very severe late syphilitic lesion, in which no mercury had ever been given. Drysdale having so recently adopted the use of mercury, is, of course, somewhat chary in its administration, and thinks it valuable in the secondary stage alone. It must be confessed that his article is of no practical value, though by experience in his new field he may make useful observations. In a doctrinal point of view these two articles are the most important of any of recent date. There have been others published relating to the various modes of treatment, which are of unequal value.

In the issue of November, 1874, of that very valuable and practical journal, *The Practitioner*, is a characteristic, short, and suggestive paper on "The Use of Mercury in some of the Obscurer Forms of Syphilis," by J. Milner Fothergill. This is one of those peculiar articles which, if not attentively read, is passed over as being of little value; yet if read attentively, and re-read, its merits are appreciated, and it then offers food for careful thought. The obscurer forms of syphilis meant by the author are those late, and in some cases difficult of recognition, conditions of impaired nutrition which are so often met with in general practice, due both to acquired and inherited disease. The author shows that while mercury may, if injudiciously administered, induce tendency to mal-nutrition, it may, by careful employment, produce the best results. He says, very truly: "The fact should appear that there are conditions of anæmia associated with syphilis, just as there are states of anæmia found in connection with malarial intoxication, with suppressed gout, or with lead poisoning." And further on: "Under such circumstances the building up of the blood by iron is frustrated by the action of the poison. The removal of the virus by its own specific—quinine, potash, and iodide of potassium—often relieves the anæmia ere iron be given. So in syphilis: the administration of mercury resulted in the palliation of the anæmia of syphilis, and facilitated the blood formation under the hæmatenic." There are certainly few

* Read November 26, 1875.

who will deny this clear statement. Going on further in the study, M. says: "One of the most unfortunate matters in the therapeutic use of mercury has been the forgetfulness on the part of those using it of its generally destructive action on the blood and tissues, and, indeed, not that only, but even a spare diet has often been conjoined with it. No wonder, then, that the mischievous consequences of the administration of mercury became vividly apparent. But can we say that some fault does not lie at the door of the administrator who is oblivious of this action?" It is certainly gratifying to find in an article such sound views, and it is to be hoped that they will be extensively read. The last question quoted is one which is particularly striking to those who read the various wild attacks of men, who generally are those of little experience, against this invaluable agent, and an impartial observer may certainly with justice inquire whether or not the agent is at fault in cases of disaster by its use, or whether it is due to some shortcoming of its administrator. Personally I have arrived at a high appreciation of the value of mercury by impartial observation of a very large number of cases of syphilis, having followed in a comparative manner all forms of treatment. I have elsewhere expressed myself as strongly in favor of its use, though, of course, I recommend that all due caution should be exercised. Fothergill puts the question as to the use of mercury in syphilis in a very apposite manner. He says: "What we should strive after is to get the good effects of a mercurial course upon the syphilitic virus, and its consequential results, while at the same time we protect the organism against the evil effects of the action of the mercury itself." We ourselves hardly think that the evil effects are really as great as they appear to the mind of Fothergill, who in his early education was taught to regard it as a poison, being later on converted to its adoption by successful experience. The necessity for the prolonged treatment of syphilis is clearly shown by the author, whose remarks thereon are very practical.

Another paper on the treatment of syphilis, especially of the secondary stage, is from the pen of Mr. Milton, of London, "On the Treatment of Secondary Syphilis" (*Edinburgh Med. Jour.*, March, 1875). The author is an advocate of mercury judiciously administered. He calls attention to the futility, even injuriousness, of giving mercury to, or even attempting to treat persons of irregular habits, especially those who indulge in drink. The directions for treatment, as set down by Milton, are very judicious, and include a preparatory course, directions for the avoidance of injurious effects, and for gaining all the curative benefits of mercury, and for a subsequent or supplementary course with the iodide of potassium. He advocates the plan of what we now term interrupted treatment, using in the main moist mercurial fumigations. Even if a person does not regard as necessary all the details advised by Milton, he will concede that they may be beneficial, and that the scheme of treatment recommended is based upon common sense, and is the result of long and careful study. The article is well worth study in connection with the others already considered. There is in it a temperate manner of statement, which is becoming to a scientific inquiry. Another noticeable article is by J. R. Lane, of London, which is the result of his study and observation for twenty-three years. It contains no new facts or striking assertions, yet as a reflection of such a long experience it is of much value. The author is an advocate of mercury and iodide of potassium in the treatment of syphilis, the indications for which he reviews in a very candid manner. He is a believer in the curability of syphilis, as shown by instances of reinfection, and by the fact that those who have been syphilitic may in time beget healthy children. Lane thinks that mercury should be given as soon as the chancre is pronounced to be syphilitic; by so doing he thinks he has in many cases prevented any further manifestation of the disease. He likewise, while he endorses the agent, advises caution in its use, and in phagedenic complications, its discontinuance. He is disposed to rely upon the natural tendency to resolution in cases of mild secondary disease, and, while to persons of good health he gives mercury, he proceeds with caution in those of the so-called strumous diathesis. While he advocates, like Ricord, protracted courses of treatment, he does not think that subsequent medication by iodide of potassium is necessary. As to the form of the drug, he prefers blue-pill, guarded by opium, and thinks that administration by the mouth is preferable to other methods. Iodide of potassium is much relied upon by him in the tertiary stage, and he thinks that its power, as well as that of other iodic salts, is intensified by the addition of carbonate of ammonia, and that the therapeutic value is enhanced by the simultaneous use of the decoction of sarsaparilla, and he regrets the disuse into which the latter preparation has fallen. The remarks on the intolerance of iodic salts are of practical interest. Lane says that he has descended as low as to half a grain of iodide of sodium, and by slowly accustoming the system to it, he has raised the dose to twelve and fifteen grains. He mentions a case of intolerance of the potassium salt in which he produced tolerance of the sodic. As to the value of the iodides in secondary syphilis, we are glad to see that Lane is very emphatic, as in that stage he considers them harmful. Among German authorities no one is deservedly more worthy of attention than Von Sigmund, of Vienna, whose articles on the treatment of syphilis, particularly by the inunction cure, are noticeable for their practical character as well as a minute knowledge of the indications for the varying phases of the disease. His latest contribution was written for the *Italian Journal of Venereal and Cutaneous Diseases*, issue of February, 1874, and is entitled, "The Proper Time to Commence the Treatment, and the Choice of the Method." The pith of the article may be stated in the following conclusions: 1. The methodical general treatment of syphilis should be, as a rule, commenced when undoubted signs of the general disease are manifested, namely, at the evolution of the secondary lesions. 2. Mercurial preparations are to be preferred. 3. Treatment should be kept up uninterruptedly or periodically, according to circumstances, as long as the symptoms of the disease persist or reappear. 4. Intercurrent diseases should be treated as in a non-syphilitic subject. 5. Hygienics and tonics should be used in each case, and the diet should be supporting. He prefers in general inunctions, uses the bichloride of mercury subcutaneously in appropriate cases, and has derived benefit from calomel thus administered, which, if used in small quantities, will not produce abscesses. He urges care in the administration of medicine, and an avoidance of overdosing. As an adjuvant to mercury, he thinks iodide of potassium to be of benefit, but of no further value. The paper, though short, is eminently useful and practical, and we regret that space does not permit a fuller consideration of many of its points. The opinion that mercury should be withheld until the evolution of the secondary stage is particularly noticeable, and coming from such a man deserves attention; certainly in all but exceptional cases this method is, in the end, most satisfactory. Schutzemburger,

("Radical Cure of Syphilis by Subacute Hydrargyrosis" *Lyon Méd.*, July, 1874), also is an advocate of mercury, and he believes that by it syphilis may be radically cured. His method of treatment is by a system which he calls subacute hydrargyrosis; in other words, he keeps a patient for a period of time under the influence of mercury in a mild manner, without the production of any toxic effects. He also prefers inunctions above all other methods, as he thinks that they act more rapidly and surely on the system. He advises a preparatory treatment, such as baths, sudorific decoctions and purgatives, after which he uses, every second day, an inunction of 30 to 90 grains of mercurial ointment, in general 30 to 25 of such being sufficient. It is necessary to stop if full salivation is induced, but not on account of mild buccal lesions. S. says that he has thus cured many severe cases. The great value of the inunction cure is further attested by a remarkably forcible paper by Panas, "The Treatment of Syphilis by Mercurial Frictions" (*London Medical Record*, January, 1874.) In speaking of the alleged disadvantages of this method, he thinks that they are much overstated and readily avoided, and that the advantages far preponderate in their favor. He considers that stomatitis should not, and need not, be induced, and he gives directions (of course already well known to us) for its avoidance. When mercury enters the economy through the skin, Panas thinks that it is not decomposed in the circulation as when taken by the alimentary canal. The usual quantity of mercurial ointment used by P. is 90 grains daily. He claims that he has thus cured many severe cases, and speaks with emphasis of the necessity of treating infantile syphilis in this manner. Though the paper contains nothing really new, it is of much interest on account of the confirmation which the experience of the author gives to claims which are extensively made for this valuable treatment. Certainly the author is perfectly correct when he states that it acts very beneficially, particularly in hereditary syphilis. His remarks on the failure of the proto-iodide and the bichloride of mercury are somewhat surprising, particularly as to the former. Evidently impressed with the views advocated by Panas, Augustin Guénel, of Paris, takes as the subject of his inaugural thesis ("Etude sur les Frictions mercurielles dans des formes graves de la Syphilis," Thèse de Paris, 1874), the study of this method in severe forms of syphilis. Though his personal experience with the inunctions is necessarily limited, he has collated with great care, and has well reported, a large number of cases of various neuroses, presenting severe lesions of syphilis, in some of which very delicate tissues were involved, in which a cure or great benefit resulted from their use. As showing, then, the experience of many prominent French surgeons, Guénel's conclusions, which are as follows, are worthy of record: 1. Mercurial frictions, properly used, have none of the drawbacks which is attributed to them. 2. They do not disturb the alimentary canal. 3. They are successful very often in cases where internal treatment has failed. They should be employed immediately in grave forms of syphilis, in which the lesions compromise the life of the patient or an important organ. 4. They are especially indicated in syphilis of the cerebro-spinal system, and of the tissues of the eye. 5. They are of as much value in the tertiary as in the secondary period. This latter conclusion suggests to us a capital paper by Dr. Sturgis "On the Use of Mercury in the later Stages of Syphilis (*American Journal of Medical Sciences*, January, 1875), in which he clearly shows the necessity for the administration of mercury in late stages of syphilis. There undoubtedly is a lurking opinion in the minds of many, whose experience in the treatment of syphilis is limited, that the iodide of potassium is the only remedy necessary in tertiary syphilis; some, indeed, go so far as to think not only that mercury is contraindicated, but that it may even be then harmful, if not unnecessary.

Sturgis clearly shows that the iodic salt is often powerless against late syphilitic lesions, or that its action is unnecessarily slow. In such cases Sturgis states that a combination of mercury with the iodic salt is necessary, an opinion which I heartily endorse, as almost every day I meet with instances showing this necessity. Sturgis also gives preference to inunctions applied continually to the soles of the feet, and advises that the iodide should be simultaneously administered. He calls attention to the value of the oleate of mercury as a readily absorbed, cleanly, and efficacious agent, which may be used of a strength as high as 20 per cent. The bichloride alone is not well thought of by Sturgis. The combination treatment, as thus indicated, should be used until all lesions have disappeared, or until the condition of the patient renders it necessary. Acton has for many years been known to be an advocate of the use of mercury in syphilis; and in a recent address before the British Medical Association ("On the Modern Treatment of the Advanced Stages of Constitutional Syphilis," *British Med. Jour.*, Aug., 1875), he reiterates his views. He urges the necessity of preventing syphilis, and states that he has found that in Edinburgh it is very severe. In the secondary stage he advises mercury; thinks that the iodide of potassium is only good in the tertiary stage, and that a mixed treatment is beneficial in many instances of late manifestations. Very similar views are offered by J. K. Spender ("The Treatment of Syphilis," *Lancet*, 1874), who has from time to time written on the treatment of syphilis. He thinks that in secondary syphilis a mixed treatment, in some respects differing from the one in vogue among us, in that he gives the mercury in the form of gray powder instead of one of the iodides, or the bichloride combined with iodide of potassium. In the tertiary stage, however, he uses the combination with the bichloride, together with tincture of bark. The benefits of most mercurial fumigations have been treated of by several authors. Foye, of Boston, brings out a very handsome little volume, entitled "The Treatment of Syphilitic Disease by the Mercurial Vapor Bath," 1874. The work is a curious mixture of the views and cases of Langston Parker and Henry Lee, with a few unimportant additions by the author. As endorsing the treatment, the views of Foye may be interesting, but there was little necessity for a book of the kind. It may be stated that the apparatus for this treatment, as devised by the author, is both simple and complete. Mr. J. St. John Wilders ("The Treatment of Syphilis by Moist Mercurial Fumigation," *British Med. Journal*, Jan., 1870), takes exception to what he considers to be slighting language of Lane in the paper already considered, and writes a very eulogistic contribution as to the value of moist mercurial fumigations in syphilis. Wilders was the pupil of the late Langston Parker, and is equally as zealous in favor of this treatment as was his predecessor. He claims that the treatment is neither troublesome nor dirty; has no depressing influence on the patient, but is, on the contrary, a cleanly, rapid, easily manageable method, powerful in action, and least of any harmful to the constitution of the patient. In speaking of ninety-one cases, treated and reported by Parker, he says: "I can most fearlessly affirm that they are a trustworthy record of the marvellous efficacy of this treatment." In support of his

assertions he details a bad case, which being uninfluenced by other methods was happily cured by the vapor-bath treatment. It is somewhat singular that in France, where the study and treatment of syphilis has been carried on by so many observers, that the mercurial vapor baths have not until recently been used. Perhaps this is an instance of a scientific exclusiveness on the part of the French which is now happily passing away in a measure. Horteloup ("Traitement de la Syphilis par les Fumigations mercurielles," *La France Médicale*, 43 and 44, 1875) details his experience during the years 1873 and 1874 in the treatment of 145 syphilitic patients having such lesions as buccal mucous patches, the same in an hypertrophic form on the anus and scrotum, as well as early exanthems, such as roseola, simple papulæ, and those with slight ulceration. Twelve of these treated early in his experience were not benefited, and he thinks that the want of success was due to his then experience. There were 43 who were decidedly ameliorated, some of whom would have been cured had they persisted in the treatment. But the number really cured was 81, in whom the disease assumed a mild form. The average number of fumigations used was 13, and the agent calomel, according to the plan of Lee, of London. H. thinks that in 32 cases he failed; some of them were examples of precocious syphilides, and others of the dry squamous form. In many of these he used as many as 56 fumigations. In several cases of deep ulceration, and in certain tubercular eruptions, he observed great benefit from the simultaneous use of the iodide of potassium, with the bath treatment. As to the drawbacks, such as stomatitis and a sense of suffocation, he thinks that they are very trifling and readily obviated. Horteloup leans to the opinion that more benefit is derived in cases of superficial ulceration than in those of dry scaling syphilides. This latter experience strikes us as being peculiar, as in very many instances of intermediary and late-scaling syphilides we have found these baths to remove them when they had resisted all other methods for a long time, and carefully employed. According to Horteloup, moist calomel fumigations may be employed for syphilis in the following conditions, administered alone: in cases of early ulcerating rashes, mucous patches, impetigo (sic), ecthyma. 2. Administered simultaneously with the internal use of iodide of potassium, they are of benefit for the later lesions: Tubercular, ulcerating, pustulo-crustaceous, and deep ecthyma. As a record of experience the paper of Horteloup is worthy of study.

The value of natural sulphur waters in the treatment of syphilis has also been studied by several observers. Two brochures of pretentious size have been written by physicians who have large personal experience in this method of treatment at the springs. The first is by Schuster ("Bemerkungen zur Behandlung der Syphilis," Berlin, 1874), while the second is by Reumont, who has previously written two works on this subject. They both reside at Aix-la-Chapelle, and evidently have studied the question as to the indications for the advantages and mode of action of the baths, and of the waters taken internally, in a very praiseworthy manner, and there is in their works an absence of that vein of empiricism so frequently met with in such productions. The chief value of this method of treatment is in late chronic and obscure cases, and the facts given confirm what we already know of the value of this combined internal and external treatment. No noticeable facts or new views are brought out, as both works are a repetition of what we already know. In the same vein is the Parisian Thesis of St. Paul ("Étude sur la Medication thérmale sulphureuse," 1874), whose work is a compendium of facts observed by others. Another advocate of this treatment is Dr. Page Bordes, who claims ("Du Traitement des Maladies syphilitiques par les Eaux minerales d'Aulus." *Tribune Médicale*, Aug., 1874) that the mineral waters of a spring at Aulus, a little spot in the Pyrenees, are of great benefit in the treatment of bad cases of syphilis, and that the natural advantages of the place are excellent in a hygienic point of view. Finally as to this method Grandidier ("Ueber Lungen Syphilis und ihre Heilbarkeit durch die Schwefelquellen zu Neundorf," *Berliner klin. Wochenschrift*, No. 15, 1875) states that among several hundred cases of constitutional syphilis he has treated thirty with lung affection. The patients were adults, and the lesion most commonly involved the right middle lobe near the base, very rarely the left. The treatment was either by the waters alone, or combined with anti-syphilitics. One or more seasons at the springs nearly always effected a cure, there being no relapses. I give the results without comment.

The treatment of syphilis by hypodermic injections of corrosive sublimate has also been the subject of brochures and papers, in Theses of Paris by Cotte and La Moaligou, and in articles by Cullingworth (*Lancet*, Nos. 19, 20, 21, 1874), and Profeta (*Annales de Dermat. et Syphilographie*). No new facts whatever are adduced, and the general conclusion of the authors is, that in a limited degree and in certain peculiar cases this method is valuable. Such is the accumulated knowledge to be gleaned from papers published since January, 1874, by the advocates of the use of mercury in the various forms in syphilis. Let us now review the labors of the antimercurialists. The most pretentious work is that of Proksh, entitled, "Antimercurial Views as to the Treatment of Syphilis." His work is an octavo of nearly two hundred pages, and its perusal betrays a lack of knowledge as well as a bigotry of mind of the author. He is a decided antimercurialist, and sums up his conclusions as follows: Mercury is not an antidote to the syphilitic poison. It merely causes the more rapid disappearance of its lesions or symptoms. 2. We do not know the effect of mercury, or even of syphilis. 3. Syphilis is cured by the healing power of nature alone, assisted by a simple topical, symptomatic, and dietetic treatment. 4. During a mercurial treatment the study of the pathology of syphilis is impossible. 5. Mercury employed in hospitals for syphilis favors the development of scorbutus and gangrene, and is injurious to such patients by its vapors.

Comment on such remarks is certainly unnecessary. It is an interesting question to know what kind of experience and line of thought led a man to such desultory and incoherent views; still, they are on a par with those recently put forth by Hermann, of Vienna, who has long been known as a rabid antimercurialist. The present paper ("Sur la Nature des Affections Syphilitique et le Traitement mercuriel," *Gazette des Hôpitaux*, Jan., 1875), which as a model of incoherence is inimitable, was, strange to say, read before the Academy of Sciences of France, to which body the author addressed it. Hermann states that he founds his doctrine, as he calls it, on twenty thousand cases of cure, and he claims that in his hospital the percentage of relapse and death is much smaller than in the general hospital of Vienna where mercury is used. The present paper should be judged not only by its own claims, but also by reference to a work of large size published by the author a few years ago, "Ueber die Wirkung des Quecksilbers auf den Menschlichen Organismus," in which certainly there are more instances of highly

questionable diagnosis and false argumentation, than in any other of equal size with which we are familiar. Hermann's conclusions are: Syphilis should be considered as a local disease having consecutive forms, which bear intimate relations with the original lesions. 2. Mercury should be banished from treatment. 3. Consider the so-called constitutional lesions as the effect of mercury. The falsity of the last conclusion is well shown by a perusal of the paper of Keyes and Van Buren already alluded to, and is made manifest very often in practice, in which cases of tertiary syphilitic lesion present to us without previous treatment owing to various causes. The same objection may be urged against Hermann which applies to almost all writers of his faith, namely, that they are blatant with dogmatic and questionable statements, and that they present no solid facts. This criticism is certainly applicable to a paper by J. R. Beck ("On the Use of Iodide of Potassium in Syphilis," *Phil. Med. Times*, March 13, 1875), which is really a dogmatic assertion that mercury merely masks syphilis, causing its manifestations to appear later on in a malignant form, and of course doing infinite harm. If such a statement was based on any facts, or upon careful reasoning, it should receive attention, but when it stands alone, and is used somewhat as a taunt to those who believe in the efficacy of mercury, it carries with it no weight. The author offers two cases of late syphilis in which iodide was very beneficial as food for contemplation for mercurialists, whose only comment will be that they are surprised that the author thought them at all unusual.

In the same vein Watson read a paper "On the Uselessness of Mercury in Syphilis (*London Med. Record*, Dec., 1874) before the Medico-Chirurgical Society of Edinburgh. This paper is more temperate in tone than many others, still it lacks reason and facts; its gist is simply that the author does not think mercury useful and necessary except in some cases. We find again that time-worn statement, that the drug causes tertiary lesions, which is the key-note of the faith of all antimercurialists. Watson also urges the fact that without mercury syphilitic lesions will disappear, and then considers this a valid reason why it is useless. He fails to tell us—perhaps he does not know—of the calamities which often happen to those who are thus treated. Indeed he does not consider the fact that such a statement is far too sweeping, as it is *only some* of the lesions which are so ephemeral in character, and if his experience is in any way extended he ought and must have met with cases which would not get well without mercury. It is certainly to be sincerely hoped that before any more antimercurial articles are written that some new, undoubted facts will be observed, as such now are merely repetitions of statements which will not bear a crucial test. Hardaway writes a very temperate paper on the non-mercurial treatment of syphilis (*St. Louis Clinical Record*, May, 1875). He endorses the view of Diday and some others, that syphilis is in general mild, though in some cases its course is severe, hence that there is a mild and a severe form. Like Diday, H. regards the use of mercury as unnecessary in the mild form, which he thinks should be treated by tonics, on general hygienic principles. In severe cases he relies upon the agent, but he thinks that its long-continued use will produce disastrous effects. In support of the treatment of syphilis by the tonic plan H. cites two cases thus managed and cured, which respectively, in five and two years, have presented no relapses. At first thought these might appear as carrying great weight against the use of mercury, yet such conclusions must be accepted with great caution, as sufficient time has not yet elapsed, nor are the cases sufficiently numerous upon which to form opinions. It is certainly true that in some cases, owing to some peculiarity of the system, which is only affected by syphilis in a very mild and ephemeral manner, and for a tonic treatment, and even with no treatment, the normal standard of health will be regained; but such cases are exceptional, and the opinion of the really sound and scientific observers of large reading and experience is emphatic in favor of the absolute necessity for the administration of mercury in the early stages of syphilis, in order to prevent ulterior trouble. Hardaway's paper is a very creditable one, and stands in marked contrast with the other ones of extreme statement which we have considered.

In conclusion, gentlemen, let me thank you kindly for the honor conferred upon me in selecting me as the person who should prepare for you the report of progress made in this interesting and important field.

Reports of Hospitals.

BELLEVUE HOSPITAL.

Reports of Practice and Peculiarities of Treatment.

Pott's Disease of the Spine—Treatment by Means of the Plaster of-Paris Jacket.

This method of treatment, just now, is very promising. It is simple, is within the reach of every surgeon, and thus far the results attained have been eminently satisfactory.

The jacket is applied in the following manner: Have the patient put on a light wrapper, and then, by means of a pulley attached to straps which pass through the axillæ and secured to a cross bar over the head, suspend him completely, or as nearly so as possible. In this way the weight of the body is made to act as a counter-extending force, and removes all pressure from the diseased surfaces of the bones. Now, while suspended, draw the wrapper down smoothly over the trunk and hips, and then with a roller-bandage filled with plaster begin two or three inches below the crests of the illii, sufficient to secure a firm hold upon the pelvis; first making two or three extra turns of the roller at this point, and then embrace the body by successive turns until the entire trunk is encased to the armpits. If the disease is high up in the dorsal region, the bandage can be carried over each shoulder like a pair of suspenders. It is proper to place a roll of cotton upon each side of the spinal column opposite the seat of the disease, and the bandages may be reinforced by strips of tin made rough like a grater to prevent them from sliding, if the size of the patient or other conditions seem to demand it. Two or three rollers are usually sufficient to make a substantial jacket, particularly if they are supported by the tin strips. There is one point with reference to padding the trunk with cotton or other yielding material before applying the roller, and that is, do not pad any more than is absolutely necessary, for in so doing the irregularities of the surface are almost entirely obliterated, which is just the thing to be avoided. It is the gentle moulding of this jacket to the depressions and elevations upon the surface of the body that enables it to accomplish its work and be worn without complaint. Whereas if the trunk is padded with cotton to any great extent, the jacket

cannot get sufficient hold to keep the pressure off the diseased surfaces, consequently is thrown one side as inefficient. The straightening out of the patient, so to speak, can be done in any manner the ingenuity of the surgeon may devise. If the patient is a child, for instance, this can be easily accomplished by placing him across the lap of an assistant, who shall separate his thighs until all the extension is made which is necessary. Now, it will be suggested, can respiration be carried on properly while the trunk is encased in such a fixed jacket? Experience so far has proven that nature will take care of that. Indeed, it seems as though a very great benefit is to be derived by keeping the ribs quiet, for they are thus prevented from producing constant rubbing *at or near the seat of the disease in the spinal column.*

Again, suppose abscesses are present, how are they to be managed? Simply make a window in the splint, and then the discharge is placed at the command of the surgeon as well as though no jacket were present.

Suppose the patient complains of the jacket, that it hurts him, that it does not give him ease from pain, etc.? Remove it at once; find out where the difficulty is, and remedy it while applying another, for it may be said with a very great amount of certainty, that the fault is with the surgeon and not with the plan of treatment.

Now, all these points were illustrated in a bright little girl before us, æt. 12 years, who had been wearing one of the best constructed braces that American or foreign ingenuity has produced, but which failed to afford the relief desired. Since the plaster-of-Paris jacket has been applied, she can ride in the cars and walk with perfect ease and comfort, and has gained several pounds in weight.

HYDROPS-PERITONEUM.

Two or three points were illustrated by this case, the history of which is as follows: A female, æt. 40, with unimportant family history, and accustomed to the use of alcoholics taken upon an empty stomach, was admitted to the hospital October 7th, 1875. She had several attacks of epistaxis, and passed some blood by stool five weeks previous to admission. One week after she noticed that her feet were swollen, particularly at night. The œdema extended upward, and at about the same time she first noticed some enlargement of the abdomen. At our visit the abdomen was very large, and the accumulation of fluid had become burdensome. The case was therefore one which illustrated a large accumulation of fluid in the abdominal cavity with more than usual rapidity, never having before suffered from ascites.

The case illustrated another point, namely, that œdema of the lower extremities precedes the notice of abdominal enlargement, which was regarded as in keeping with the general rule.

Early tapping, followed by a tonic plan of treatment, was advocated for this class of cases, and was at once introduced. Repeat the paracentesis as often as the accumulation recurs. In this case the probable cause of the ascites was cirrhosis of the liver.

EPITHELIOMA—TERCHLORIDE OF ANTIMONY.

The growth had been developed upon a cicatrix following a burn, and it was hoped that the cell action could be so modified by the application of the terchloride of anatomy as would avoid an operation. It was situated upon the anterior aspect of the forearm, near the wrist, and was a little more than an inch in diameter. The surface of the growth was touched with the caustic, exercising due care that the surrounding tissues escaped, and it was to be repeated every six or seven days. The case progressed favorably.

CHRONIC HEART DISEASE.

The points of interest in this case relate to situation of the apex beat and the innocuousness of valvular lesions. A male patient, æt. 28, had had repeated attacks of articular rheumatism some years ago, and had since been told by his physicians that he had heart disease. He had not, however, experienced any trouble which he could refer directly to the heart. Upon physical examination the apex was found beating distinctly in the *fourth* intercostal space, and that while the patient was standing. There was no enlargement of the spleen or pericarditis with effusion, or increased area of cardiac dulness, or other condition which would account for this exceptional situation of the apex beat. Auscultation revealed a mitral regurgitant murmur of moderate intensity, and a very slight aortic regurgitant murmur. It was thought altogether probable that these lesions had been present for many years, and that they were doubtless the result of rheumatic endocarditis. Especial attention was drawn to this fact, namely, that we do not, as a rule, have evils resulting from valvular lesions of the heart until they have allowed of more or less enlargement of the organ, and that the graver difficulties, such as dropsy, dyspnœa, etc., do not, as a rule, occur until the heart has become dilated. Such murmurs, therefore, under circumstances like the present, relate chiefly to the future of the patient. They may at some remote period give rise to trouble, but they may be carried for years without becoming of especial importance, unless an intercurrent attack of endocarditis is developed. This point was regarded as specially important in connection with prognosis, and the idea that a grave prognosis must be made simply because a valvular murmur is present, should be cast aside, for the *intensity* of the murmur gives no reliable information with regard to the extent of the lesion.

PLEURISY WITH EFFUSION.

The point of special interest in this case relates to treatment, and it was made more interesting from the fact that a plan had been marked out upon theoretical grounds, by a group of students, which consisted of diuretics, perhaps hydragogue cathartics, and counter-irritants. None of these measures, however, were resorted to for the removal of the fluid, but under the influence of a full *tonic* course, with *good diet* the fluid in the pleural cavity was rapidly disappearing and the strength of the patient was increasing. Only a single small blister had been applied.

TYPHOID FEVER.

It was remarked by the visiting physician, that this fever is the only disease, except a double quotidian intermittent, which gives two full thermometrical curves within twenty-four hours; that is, two full intermissions and two exacerbations. This will, if true, account, in a certain number of cases at least, for the high temperature met with in typhoid fever in the morning, and is also a good aid in making a positive diagnosis.

FRACTURED CLAVICLE.

The bone in this case was fractured by *direct* violence, having been placed in forcible apposition with the hoof of a horse. One point with regard to treat-

ment was noted, and that was, that any dressing to be efficient must hold the *scapula* in a fixed position.

FRACTURE OF THE PATELLA.

A few points of interest were noted in connection with a case belonging to this class. A man, æt. fifty-five years, had slipped and fallen upon the pavement in such a manner as to strike squarely upon his knee, and the result was a transverse fracture of the patella. In this history there were two points, namely, a fracture of the patella by direct violence, which has been said never to occur; and a *transverse* fracture as the result of that direct violence, which has been said to occur *only* from muscular violence. The case illustrated another point, namely, that the separation of the fragments is not always, perhaps not in a majority of cases, due to the action of the quadriceps femoris muscle, but to a distention of the joint by the effusions incident to an acute synovitis. This introduces an item with regard to treatment, and that is, apply cold, and *always wait* until the swelling and inflammation have subsided before applying any permanent dressing. The condition of the knee suggested another thought, namely, that when there is serious joint complication in cases of fracture of the patella, a portion of the cartilage covering the *inner condyle of the femur* is usually chipped off. The same case presented another interesting feature; namely, a fracture of the patella had occurred upon the opposite leg five years ago, which was doubtless the result of muscular violence, for while carrying a heavy weight he slipped, and in the attempt to save himself an extra strain was brought upon that leg, the bone gave way, and he fell to the ground. The union in that instance had been exceedingly good, and perhaps bony.

Progress of Medical Science.

SECTION OF THE LATISSIMUS DORSI FOR ROTARY LATERAL CURVATURE.—Prof. Lewis A. Sayre recently delivered a clinical lecture on the above subject, and, at its close, performed a very interesting and novel operation. He explained his use of the adjective *rotary*, applied to lateral curvature of the spine, as denoting the fact that a rotation of the vertebræ took place prior to the development of the lateral deformity. It was very important in treating this form of curvature to ascertain whether its original seat was in the lumbar or in the dorsal region. It was in the curvatures commencing in the latter region that the primary rotation was most marked. The lateral curvature that begins in the lumbar region was due, usually, to an inequality of the two lower extremities, causing the plane of the pelvis to be inclined to one side. Such a deformity, if treated in its inception—before the development of structural changes—could be remedied by simply wearing a thicker sole on the foot of the shortened limb and by appropriate gymnastic exercise. The mode in which the dorsal curvature begins was a little more complicated. In this case the origin of the deformity was ascribed to a preponderating action of the serratus magnus muscle of one side over that of the other. The unequal action might arise from a habit of carrying one shoulder backward more than the other, or of carrying one hand behind the back, thus drawing the scapula backward toward the spine, by which the great serratus muscle, which arises from the base of the scapula, is rendered tense, with full power to act on the ribs. The latter rest with their angles against the transverse processes of the vertebræ, and their heads upon the bodies of the vertebræ; thus, when the serratus magnus of one side is contracted, a powerful leverage is exerted upon the spine, which causes a rotation upon itself. "This rotation produces tension of the latissimus dorsi upon the opposite side, and keeping up a constant irritation, stimulates it to undue contraction, which bends the body to that side, thus producing the lateral curve." The curve having been once established, the superincumbent weight of the body constantly tends to increase it.

It was observed that in "the very early stages of this deformity the distortion can be rectified by instructing the patient to use his muscles so as to cause their development in exactly the opposite direction to that which has produced the deformity." Various devices were mentioned by which this end might be accomplished—such as, balancing a book upon the top of the head while the patient walks about the room; gymnastic exercises; sitting while at study upon an uneven seat or triangular chair, so that there will be danger of falling over unless the body is properly poised; a spiral corset which has a constant tendency to untelescope itself and thus keep the patient straight, and the like. Such methods of treatment, it was observed, apply only to those cases in which permanent structural changes have not yet taken place.

At the conclusion of the lecture a case of lateral curvature in a man was presented, in which the latissimus dorsi had become contractured. On stretching the man out by means of a sling passing under the arms and secured around the chin and occiput, the apparatus being suspended from above and worked by a cord and pulley, the muscle was brought out prominently into view and was evidently the means of preventing the body from straightening itself. When the muscle was pinched spasmodic contractions of nearly all the muscles of the body were produced. It was claimed that attempts to stretch this muscle would only serve to irritate it and aggravate the condition. The professor therefore proceeded to divide the muscle subcutaneously; an operation, as he stated, never before intentionally performed for the relief of this deformity. The immediate effect was entirely satisfactory. "The patient was straightened almost upon the instant, so far as the lateral curvature was concerned, the angle of the ribs upon the opposite side being about the only deformity left." The pain of the operation is stated to have been only trifling; and immediately after, having been removed from the gallows, the patient expressed himself as feeling perfectly comfortable. Having been placed in bed a broad band was passed around the upper portion of the trunk and was secured by an india-rubber strap to the fixtures upon one side of the bed, and another around the pelvis secured in the same way upon the opposite side. Between these two elastic forces the body was retained in a perfectly straight position.—*The Medical and Surgical Reporter*, Oct. 23, 1875.

BATTEY'S OPERATION.—Dr. Battey, of Georgia, has a number of times performed ablation of one or both ovaries, with the avowed object of artificially inducing the menopause for the relief of a "diseased or pernicious ovulation." In all, he has operated ten times; in two instances the result was fatal, and in eight successful. Only such cases were deemed suitable for the operation as were otherwise incurable. The conditions for which the operation was performed in the

different cases have varied considerably. Thus in one case the patient had amenorrhœa, convulsions, recurring hematocele, repeated pelvic abscesses, incipient tuberculosis from pulmonary congestions, etc. Several were cases of ovarian neuralgia; in some there was intractable dysmenorrhœa, with pelvic deposits of old lymph; one had ovarian insanity, etc. We are assured that in no case has he operated where any other method of treatment offered any prospect of a cure.

Dr. Battey's views with regard to this operation are given somewhat at length in the form of an "interview" between the author of the operation and Drs. Yandell and McClellan, in the October number of the *American Practitioner*. In answer to a question in reference to his method of operating, Dr. Battey replied as follows:

"I place the patient upon the left side, semi-prone, retract the perinæum with an old-fashioned Sims' duckbill, having a broad but rather short blade, that is but little cupped, which I find very desirable. The cervix uteri is now seized with a stout volsella and drawn down under the pubic arch. The incision is made in the median line of the posterior vaginal *cul-de-sac* with scissors, and from an inch and a quarter to an inch and a half in length, the latter preferable. The incision extends at first down to the perinæum, when, if there be no bleeding, the serous membrane is opened. The speculum is now removed and the index finger passed into Douglas's fossa, to hook down one of the ovaries and bring it into the vagina, while an assistant, by pressing the hand upon the hypogastrium, depresses the viscera in the pelvis. Occasionally there is advantage in turning the patient supine, that the viscera may gravitate into the pelvis. Often the use of a suitably constructed forceps is required to assist in bringing down the ovary. A temporary ligature is cast around the base of the ovary, and the other organ similarly treated, when they are removed by écrasement, about ten minutes being consumed in crushing the pedicle of each ovary, the temporary ligatures coming away with the ovaries. No suture is used in the vaginal wound, nor is any tent or drainage-tube employed, as a rule. In several of my cases the ovaries have been found to be bound down by old peritoneal adhesions, which required to be broken up by the finger, and in one case the ovary was literally dug out with the finger-nail."

In response to questions regarding the effect of the operation upon the menstrual function, "sexual desire," etc., Battey replied that he had never seen anything like proper menstruation after it; that the sexual desire, so far as he could ascertain, remained unaffected; that, aside from remaining barren, which all of the patients indeed hopelessly were before the operation, nothing whatever was lost, and there was no evidence that the patients had been unsexed by it. The term "spaying," which had been applied to the operation by Dr. Matthews Duncan in an address before the British Medical Association, was repudiated.

Typhoid Fever caused by Intermittent Water Supply.—Dr. Carpenter gives an account of an epidemic of typhoid fever which visited Croydon in 1865, and was then due to improper ventilation as regarded the sewers, all the gas from them discharging directly into the houses, and contaminating the water supply. Energetic means were taken subsequently to remove the cause, and typhoid as an epidemic entirely ceased. It occasionally happened, however, that sudden developments of severe illnesses took place in single houses or blocks of houses; every inmate suffering more or less. The situation of these anomalous attacks was found to be in the higher parts of the district, where every sanitary requirement had been complied with. After a time it was noted that those cases in which whole households were affected occurred soon after the district had been placed under an intermittent water supply in consequence of the demand for water being greater than the supply. Another point was noted, that the water obtained from these houses contained sewage matters sufficient to account for the illness of the inmates. The supply-pipes which run from the mains into the houses are often carried through made ground, or through a subsoil soaked with sewage matters. The service pipes become rapidly corroded, and pin-hole pipes are the result, letting out water under pressure, and when the pressure is removed there is intermission of supply, and nasty water is drawn into the pipe. In February last there were three cases of typhoid in the district, two of which were imported. At this juncture there was an intermittent water supply lasting several days. Five weeks after the intermission an epidemic commenced, and by April 30th four hundred cases of fever were reported. A second epidemic occurred on the 16th of September from an intermittent water supply, this epidemic also coming to a climax in five weeks. Dr. Carpenter also mentions the following important fact: In a certain street the houses are supplied from two different sources; those on one side by the Croydon Waterworks; those on the other by the Lambeth Company. The sewer is in the middle of the road, and is common to both. The fever only affected those who were supplied with water from the Croydon Waterworks. — *British Medical Journal*, November, 1875.

Redressement Brusque of Genu Valgum.—At a meeting of the "Société de Chirurgie," held on Nov. 17th, M. Tillaux presented a young man, aged 16, in whom he had performed this operation in June, 1874. The operation differed somewhat from that described by M. Delore, of Lyons. The thigh was made to rest on its inner surface on a table, so that the knee just reached the edge. The surgeon then seized the leg, and using it as a lever forcibly straightened the limb. It was necessary to break the knee, the epiphysis of the femur being separated. Both knees were operated on successively, immovable apparatuses were at once applied and kept on for two months, and at present the young man's limbs are quite straight. In the discussion that followed M. le Fort said that the deformity depends on a malformation of the anterior part of the articulation, the anterior portion of the inner condyle being too strongly developed. The genu valgum is at its maximum when the leg is extended, but disappears when the knee is partly flexed.—*Mouvement Médical*, Dec. 4, 1875.

Ligature of the Femoral Artery with Antiseptic Catgut.—Mr. Nankivell mentions five cases illustrative of the results of this treatment. In no one of these patients was there the slightest sign of secondary hemorrhage, nor was any portion of the ligature seen in the dressings.

The wound, in two cases, healed in 21 days; the others in 31, 40 and 54 days respectively. He says that it is difficult to compare the period of cure in cases treated by catgut, on the one hand, and silk ligatures on the other, from the fact of the melting away of the ligature in one instance, and the separating of the thread in the other. He does not think the presence of the catgut prevents primary adhesion of the deeper parts of the incision.—*Lancet*, December 11, 1875

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

New York, January 22, 1876.

HOSPITAL CONSTRUCTION AND ORGANIZATION.*

I.

"Hospital Construction and Organization" is the title of the book recently published by William Wood & Co. for the trustees of Johns Hopkins Hospital, Baltimore. It is the first installment of a precious succession of blessings which we believe awaits the American people in the execution of that grand inception of which a university is the centre, and this hospital is one of the earliest and most prominent outposts.

The trustees show, even in the advertisement, that they have measured the scope of this great endowment. The letter to the authors, by its greater detail, exhibits an enlightened apprehension of the various problems that are to be solved in the carrying out of the plan. The munificent donor evidently knew his men, and, while indicating the outlines of his design, wisely left expansion and details to the "discretion," "good judgment and experience in life" of those whom he felt assured would rightly estimate and operate this wondrous charity. They, first of all, resort to the method best adapted to elicit information for their own guidance, and also give it to the public that it may reap the advantage of the opinions the book expresses. We are glad to know that the authors of these essays invite a free discussion. It has evidently been their honest and modest intent to collect the best information within their reach, and to speak advisingly rather than authoritatively.

The investigation of the subjects presented in the letter addressed by the trustees to the authors involves the entire preparation, machinery and management of all classes of philanthropies. A hospital has been called "Hôtel Dieu," or hotel of God, for it is well recognized as a typical application of that charity which is not a mere humanity, but a response to the divine which is within and about us.

When, for instance, we solve the question as to the best house construction for the in-dwelling of the sick, we are compelled in the investigation to traverse those very problems which have to do with the best conditions of private houses.

The care of the sick is in many respects but an advanced study of the perfections of household administration. As, too, there are more sick people by tens of thousands in private houses than there ever can be in public charities, salient questions as to the management of all these are involved in every appreciative discussion of a hospital and its affairs. Physicians here learn most important lessons to be carried to the bed-side in every home. Nurses are here trained in the details of that attention which all sick ones require. There is a beautiful symmetry in the will of the donor in that he specifies, in connection with the hospital, a training-school for nurses, and singles out the medical college for chief prominence in its common relation to the hospital and the prospective university. While every educational interest will greet the rising Göttingen, every medical man must rejoice with the sparkling joy of true science, that now there is prospect of opening to medical education an arena such as neither the continent nor the century have before enjoyed. We wonder not that one of our authors, himself a medical professor, breaks forth in honest utterance (pp. 317–318) against most medical colleges as private educating and licensing stock corporations. He speaks of our whole system as "vicious," and glows with enthusiasm as he declares that "in the munificence of Mr. Hopkins we have the prophecy and possibility of a reform in education, which will be general in its character and permanent in its results." We recently heard an eminent Baltimore medical professor say that he was willing to see this noble plan executed, although it should submerge his own institution.

The language of the donor justifies prolific expectations beyond the hospital itself. He says to the trustees: "You will bear in mind that it is my wish and purpose that the institution shall ultimately form a part of the medical school of the University." He visioned beyond the benefit to those in the hospital, knowing that all are dependent upon the skill of the physician, and that the right application of hygienic principles here will outreach gifts by the handful into all the homes of society. In his directions as to a training-school for nurses, he puts this still further in words, "because," says he, "it will secure the services of women competent to care for the sick in the hospital wards, and will enable you to benefit the whole community by supplying *it* with a class of trained and experienced nurses."

We enter, therefore, upon the examination of this

* HOSPITAL PLANS. *Five Essays Relating to the Construction, Organization, and Management of Hospitals.* Contributed by their Authors for the Johns Hopkins Hospital, of Baltimore. New York: William Wood & Co. 1875. 8vo, pp. 358.

book not merely as we would discuss a constricted local charity, but because it involves the whole question of habitations, and bears largely on the interests of all society. The limits of a journal only permit us to indicate the more essential points and to hint at additions, without the opportunity of extended enforcement.

The authors who here present their views may well be regarded as representative men of their profession, and as such closely allied to the subjects they discuss. The cities of New Orleans, Washington, Baltimore, Philadelphia, New York, and Boston are represented by them. Five of them are physicians of prominence, and one of them is an architect, who by his two appendices has well entitled himself to be reckoned as furnishing a plan. Some of the writers have been familiar with both civil and military life, and two, at least, have evidently availed themselves of minute professional aid from architects and engineers. While the papers are of quite unequal merit, we should be sorry to spare any one of them from the compilation. If in review we seem fuller in the criticism of possible shortcomings than in bringing out the merits of these essays, it is only because such method best answers the practical results which trustees, authors, and voluntary contributors alike desire.

The site chosen is first in order before the precise location of buildings is discussed. This, fortunately, is already determined, so far as the hospital is concerned, in such a way as seems eminently satisfactory to all the essayists. Fourteen acres of high elevation, bounded on three sides by streets grading therefrom, with good surface drainage and a fall for under-drainage toward tide-water, certainly presents an attractive landscape, over which the eye of the delineator may range with delight. It is a beautiful plot, already in the city, and destined to be more so, and presents many natural advantages of position and space. The charm of this has been so great that but one or two of our authors seem to give to drainage the importance which the subject demands. One gives it but a passing line; another alludes to it only as to the carriage of surface water; a third and a fourth, while announcing the subject, speak almost entirely of sewerage, under the head of drainage, as if the two were identical. In paper five we are glad to find more detailed attention to its importance.

While we do not believe in the impurity of ground so strongly as there presented, yet the remark (p. 271) is most important, that "there should be a thorough examination as to the existence and depth of the stratum of water-bearing soil and the fluctuations of the ground-water." The retentivity of different soils and their varied needs of attention, is not always the same on all parts of the same plot, and the ground substructure should be well mapped and described before occupancy. When the facts are determined we also claim that "a system of deep drainage should be perfected, which should effectually prevent ground-water from approaching within six feet of the surface." We must never forget that character of sub-soil, rather than elevation, determines many questions of drainage.

Besides, although natural drainage may be good, and the underlying strata pervious enough for dryness in the natural state, such buildings as are here to be spread abroad suspend very many of the laws of telluric and celestial correspondence.

Erections upon and over ground disturb its temperature, moisture, evaporation, its electric condition, etc., so much that compensation is required.

The underground plan of the engineer is as fundamental as the uprising structure of the architect. Art above ground must be conservative toward the ills with which she covers the earth, unless somehow she intervenes to make the curse a blessing. This she can do, but it must be done beforehand, in order to comprehend and control the situation. We have sometimes even to complain that engineers understand levels and the arithmetic of descent better than they do the play of physical forces, and seem to think all their science consists in right fall and curve, and calibre of tubes. As the doctor must needs consult the architect, so must the engineer the physicist. We do not dwell upon gravelled walks and grass lawns and arrangement of trees, because all preparation of grounds below and on the surface should be in subjection to the law to preserve or secure the best natural conditions of building ground, and to provide compensation by extra drying facilities for those necessary or ornamental interpositions which art introduces, whether in buildings or surroundings.

While we believe in the ventilation of the earth, we are a little suspicious of heated ventilating shafts "communicating at the base with drain-pipes and conduits," unless great care is taken that they do not raise unduly the temperature of organic matter by over-heat and irregular action.

THE PROBING OF CAVITIES AFTER GUN-SHOT WOUNDS.

The importance of a thorough study of the principles of medical jurisprudence is becoming more and more apparent when we take into account the efforts of the lawyers to transfer the responsibility of death in certain murder cases to the surgeons in attendance upon them. The plea of moral insanity has been worn so threadbare, that more than ordinary pains are required to convince a jury of its truth. This does not, however, seem to be the case with what is now termed in the courts scientific murder, either by neglect or unwarrantable interference on the part of the surgeon. The first notable instance in which this plea was advanced was in the Stokes trial. It was assumed by the defence that probing of the wound in the abdomen and an overdose of morphine were the responsible causes of death. Although neither of these assumptions were substantiated to the satisfaction of the jury,

enough of doubt was thrown upon the question at issue to result in a mild verdict.

In the case of Carruth, of Vineland, who was shot in the head by Landis, a similar line of defence has been taken, and some of the surgeons in charge of the case are made to appear in a very unenviable light before the public. There is an attempt to prove that the introduction of a probe in a direction contrary to the course of the ball into the brain, excited inflammation *per se*, and caused abscesses, of which the patient afterwards died. Again, the defence claims that the abscesses were not discharged as they should have been, and that the reasonable chance of a recovery was thus cut off. There are a great many matters of fact to come up in the consideration of such questions, and it is not to be wondered at that the experts in the case have different opinions.

In view of the autopsical appearances of the brain, it is hard to prove that the probe produced extra inflammation, but the possibility of such a state of affairs is seized upon as one of the desperate chances in criminal jurisprudence. No practical surgeon will attempt to defend the passage of a probe through sound brain-tissue. It is one of those mistakes which constantly occur as the result of eager officiousness in such cases. We know it is the fashion to find the ball and extract it, if possible on the spot, as if this were the main object of all treatment; but in cases of gunshot wounds of cavities we think it is time that the fashion be changed. In the great majority of instances of gunshot wounds of cavities the mischief is done when the ball enters, while the risks of internal hemorrhage and secondary inflammations of the viscera are sufficiently great to deter the surgeon from constantly thrusting in his probe; and even if the ball be found, as the result of blind poking through vital tissues, its extraction, under the most favorable circumstances, is rarely if ever unattended with positive danger. The moral of all this is, viewed at least from a medico-legal aspect, that the less we probe for balls hidden in cavities the better.

UNNECESSARY JOURNALS.

Enterprise in journalism is, on general principles, to be commended, but it is hardly requisite for every society or every school in North America to have its so-called "medical organ." Every little while we hear the announcement of a new periodical of this sort, generally accompanied with the usual modest misgiving on the part of the editors as to its ultimate success, but invariably with an earnest appeal for the support of friends. Many of these ventures are explained on the ground of a want long felt by a particular medical community, or a particular medical school, and it is only after a signal failure that the editors are willing to acknowledge that they have made a miscalculation. But this is a matter of business which every one who is likely to be interested in journalistic undertakings should thoughtfully consider. There is, however, another element in the question which should be taken into account. These new periodicals not only take a certain share of pecuniary support from those already established, but are the means of ultimately burying many valuable communications. Besides this, every unnecessary journal tends directly to interfere with the general progress of journalism. This fact is well presented, although perhaps not from an entirely unprejudiced standpoint, by the editor of the *Canada Lancet*, in allusion to a new journal (*The Canadian Journal of Medical Sciences*), which has appeared in Ontario. He says: "It is much to be regretted that the American idea of having a 'school organ' should have been transplanted to Canadian soil. There can be no other reason for the appearance of another medical journal, especially in these hard times. There is no surplus of literary material seeking publication. In fact, Canadian journals, so far, are obliged to fill their pages with extracts and reprints. Two journals in Ontario cannot both pay working expenses, and the result of this effort, even if partially successful, will be to weaken and jeopardize the existence of both, and bring Canadian medical journalism into bad repute. It will also have the effect, if partially successful, of retarding or preventing those improvements, not only in the quality and quantity of the matter provided for the readers, but also in those looking towards the issue of semi-monthly or weekly editions, a very great desideratum in these days of rapid improvement in medical and surgical science."

HOSPITAL ABUSES.

The injustice of operating in hospitals upon patients who can afford to pay is not altogether an American institution. In a recent number of the *British Medical Journal*, a correspondent calls attention to the abuse, presenting at the same time some very damaging facts against the upright intentions of many of the surgeons who hold hospital appointments in London. In the course of his letter he says:

"If the person cannot pay the regular fee of the hospital surgeon the system is to do it for nothing, rather than the provincial medical man shall do it for a fee that will quite remunerate him. Of late it has been getting so bad, that people tell country surgeons that, unless you do it on their terms, they will go to London and get it done for nothing. At this present time I have a patient, the aunt of a banker who moves in the best society, but has the impudence to tell me that, if a large fee be charged, she will go to a charitable institution. I could tell you of dozens of cases; in fact, it is getting most monstrous. Even to-day a man worth thousands is threatening similarly unless the operation is performed at his price," etc., etc.

We have so repeatedly given parallel examples to the above as occurring in our own city, that this will

be recognized as an old story. The evil is a great, a growing one; but under the present system of hospital management, the remedy, being so radically opposed to the interests of those who hold hospital and college positions, is hardly possible of immediate application. As all cannot hold these appointments, the obscurer practitioners must struggle on as best they can, and be satisfied with the few crumbs that accidentally come in their way. If they cannot be successful, they can at least be philosophical.

MEDICAL STUDENTS' RECEPTION.

In the present number we publish a full report of the reception of the medical students of this city by the Young Men's Christian Association. We take occasion again to heartily commend the spirit which prompted such a tender of Christian hospitality. The medical student is a hard-worked, and, generally speaking, a much neglected piece of humanity. In the intervals of hard study, when he is in need of relaxation, he is literally without any kind and sympathizing influences save those which centre around an attic room in a second-class boarding-house. That he is in need of friends, comfort and sympathy, every one who has left a good home to go to a strange city, fully appreciates. It is to supply these pressing wants that the Young Men's Christian Association has opened its doors for the winter to the medical students here, and may the example be followed by similar associations elsewhere.

Reports of Societies.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, December 22, 1875.

DR. F. DELAFIELD, PRESIDENT, IN THE CHAIR.

ANEURISM OF AORTA.

DR. LOOMIS presented a specimen taken from a Scotch sailor, 33 years of age, who was admitted into Bellevue Hospital on the last day of November. He stated at the time of his admission that his father and his mother had died of phthisis. Farther than that his family history was good; that thirteen years before he had an attack of syphilis, for which he was treated with mercury and iodide of potassium, and that during these thirteen years he suffered from syphilitic manifestations, which yielded to specific treatment; that three years before he had received a blow on the left breast from a weight of three hundred pounds falling from a height, and striking with a slanting blow with sufficient force to knock him down, or, as he said, "knocked his breath out of his body for fifteen minutes." It seems that he had been unconscious for a few moments after the blow.

For the last twenty years he had performed the duties of a fireman on board of a steamer, had been a hard drinker until within two or three years, when he drank moderately.

In February last he, for the first time in his life, had a cough. It came on after exposure, and he thought that it was due to a cold. This cough was attended at times with expectoration of a glairy mucus, and at times with a muco-purulent material, and was not paroxysmal in character. He remained pretty well from last July until six weeks before admission into the hospital, when he began to cough again and to expectorate as before. Three weeks after the second commencement of the cough he spat about a tablespoonful of blood. The blood was bright-colored, and was not mixed with the sputum. After that, up to the time of his admission, he spat up streaks of blood in his expectorations, and sometimes the blood would come up clear and bright red as before.

He said that from the time he had received the blow he had pain in his left chest, which was especially marked after exercise. He would locate it at one time in the epigastrium, and at another time in the left nipple. During the six weeks previous to admission it had increased and extended into the left scapula, was of a constant and heavy character, and at times was sharp and lancinating. After the third week of the cough he began to suffer from shortness of breath, and after exertion would sometimes be compelled to lie down. There was at no time, as far as he could remember, any change in his voice, any peculiarity in the cough. He had intermittent fever at different times during the last twenty years.

At the time of his admission into the hospital he had a temperature of 102° F., pulse 109, and respiration 29. He got short of breath on slight exertion; he had a cough bronchial in character, accompanied by a muco-purulent expectoration streaked with blood, at times spitting up a mouthful of clear blood.

Within twenty-four hours after his admission his temperature was normal, and his paroxysm of fever, which was present at the time of his admission, ended in a profuse perspiration. During his stay in the hospital he had repeated attacks of fever, followed by sweating, when his temperature would return to its normal standard.

He was well nourished, had a good muscular development, a rather anxious expression of countenance, and preferred to lie partially on his left side and partially upon his back, with his head elevated. He had noticed, within the last few days before his admission, that there was some difficulty in swallowing. Before the food reached the stomach there was a painful sensation experienced. Inspection showed absence of motion on the left side, and exaggerated motion on the right side. Standing behind the patient, and casting the eye over the anterior portion of the left chest, a slight undulating motion or vibration could be noticed. It was very slight, and more apparent when a piece of white paper was laid over the infra-clavicular space of the left side. The heart was beating in the normal position with normal force. On palpation there was an entire absence of vocal fremitus over the anterior portion of the left chest, but laying the hand over the left clavicle, there was a distinct vibration of voice. There was no bulging nor motion on full inspiration, or very little, and there was at no point any pulsation over the left chest. Dr. Loomis thought that, while grasping the chest with one hand on the posterior, and the other on the anterior aspect, an indistinct pulsation could be detected. On percussion there was complete flatness over the whole of the left chest, except at the infra-clavicular space, where there was merely dulness.

On auscultation there was an absence of vesicular

respiration over the anterior left chest, and exaggerated over the anterior right chest. There was bronchial respiration at the junction of the angles of the scapula, in the inter-scapular space, and broncho-vesicular breathing underneath the clavicle in front. The heart was normal in sound, with a slight increase in force of beat, and a little prolongation of first sound, but there was no murmur. On careful listening in the inter-scapular space, when the left scapular was well brought forward, Dr. L. detected a distinct systolic bruit, but it was not detected by any others who examined the patient, in fact was not heard at all save at one or two examinations. The diagnosis made at the time before the class was: pulmonary consolidation of the left lung, with pressure upon the left bronchus, which interfered with the entrance of air into the left lung, cutting off vocal fremitus and the respiratory sounds, and that that pressure was probably due to an aneurism given off from the descending portion of the aorta while passing forward. The reasons for this were that the heart was occupying its normal position, and any idea of the existence of subacute pleurisy which the physical signs might indicate had to be abandoned. The reason for believing that the aneurism pressed upon the left bronchus was the fact that the patient had spat blood a number of times in small quantities, that he had a bronchial cough, and that he had at times difficult deglutition. The prognosis was that he would probably die from sudden hemorrhage. From that time the case went on very well, the patient rather improving than otherwise. The quinine controlled his fever, and his appetite returned. The physical signs remained, except that they were less defined. The night before his death he felt so much better that he stated to the house-physician his intention of leaving the hospital. At seven o'clock the next morning he bled two quarts, and died immediately after.

On opening the thoracic cavity the right lung was found rather emphysematous in its distention, the lower portion being in the condition of pulmonary congestion and œdema. The left lung presented the appearance on its left surface of that slow form of pneumonia called catarrhal, with a good deal of fibrous increase. The pleura was thickened, and showed the evidences of inflammation. The heart was normal in size, and so far as the valves were concerned there seemed to be nothing that would lead them to be insufficient, or give rise to obstructive murmur. At the origin of the aorta there was an atheromatous degeneration, which extended more or less throughout its whole extent. At the point where the lower portion of the descending arch swings under the left bronchus there was a fusiform aneurismal pouch, at the depending portion of which was an opening large enough to admit the end of the index finger. This opening seemed to have taken place rather slowly, from the giving way of tissues around it. At the time of the autopsy the opening contained a well-organized clot, and one was found in the left bronchus. The recurrent laryngeal was not involved. The aneurism was about the size of a hen's egg.

Dr. O'Sullivan referred to the case of a Catholic clergyman under his care, in which, although aneurism was suspected, there was nothing to indicate its existence for three months save difficult deglutition and an occasional huskiness of the voice. Subsequent to this there was a slight dulness under the left clavicle.

Dr. Beverley Robinson remarked that dysphagia was quite a significant symptom in aneurism of the aorta, while the huskiness of the voice was explained by the existence of paralysis of one of the vocal cords, which condition from the start could be distinguished with the greatest readiness by the laryngoscope.

Dr. Loomis stated that laryngeal symptoms, in connection with thoracic aneurisms, had been recognized from the time aneurisms were known to exist; but in regard to the laryngeal element as an aid to diagnosis he had not much faith. Within the past two or three years he had seen three cases of aneurism in which the diagnosis could be made by physical examination, and which were being treated by a gentleman well skilled in laryngoscopy, for paralysis of the vocal cords.

Dr. Robinson replied that these cases might have been due to coincident congestion of the vocal cords, the significant point of diagnosis by the laryngoscope being that in aneurismal tumors these cords were simply paralyzed.

[*To be Continued.*]

Correspondence.

ARTIFICIAL RESPIRATION IN APOPLEXY.

To the Editor of The Medical Record.

Sir:—The following case may be of interest, as it supports the views of Corso, the advocate of artificial respiration in apoplexy:

On the 31st March, 1875, while travelling in the cars between Baltimore and Philadelphia, Col. B., of the Military Academy at Chester, was seized with apoplexy. I had him immediately removed to the parlor car, laid upon the floor, and his clothing loosened. By this time he was entirely unconscious, his breathing was slow, labored, stertorous, and puffing; faced flushed and turgid; pulse slow, hard, and intermitting; pupils of eyes slightly contracted, but no disparity was observed between them; surface of body warm; no convulsions nor paralysis.

Fearing death by *apnœa*—face becoming more livid, the coma more profound, and the respirations feeble and labored—I had recourse at once to artificial respiration (Sylvester's method), and in the space of an hour and a quarter had the satisfaction of seeing the Colonel return to consciousness, and by the time the train reached Chester, he was in a condition to be removed to his residence at that place. I have since heard from his physician that there has been no return of the attack, and that he is now in the enjoyment of good health. So profound was the coma and so grave the respiratory symptoms in this case, that I feel assured (in the absence of all other remedies) he must have expired but for the timely use of artificial respiration.

I have recently tried Sylvester's method in a case of uræmic apoplexy without success, but in two cases of angina pectoris in which it was used, it afforded considerable relief.

C. J. Cleborne, M.D.

FRACTURE OF CLAVICLE BY MUSCULAR ACTION.

To the Editor of The Medical Record.

Dear Sir: Considering the rarity of fractures of the clavicle by muscular action, I have thought it proper to offer a report of the following case for publication.

James M., about 21 years old, catcher of the Androscoggin Base Ball Club of this city, last summer, while

playing in his position behind the striker, received a blow on his chest from the ball. It did not cause him any lasting pain, nor interrupt his playing. In the next inning, when it came his turn to strike, he struck forcibly at the ball, missed it, felt a sharp pain, and "giving way" in his left shoulder, and his arm fell to his side. I saw him a few minutes later, and found the left clavicle fractured at the junction of the middle and outer thirds, and the fragments separated. The case was treated by Dr. J. A. Donovan and myself, and the patient made a good recovery. When we questioned him in regard to the blow from the ball, he could not tell even on what part of the chest it was received. Nor could we tell from examination. From the fact that he played some time after he was hit, without any inconvenience, and from other circumstances already given, it was our opinion the fracture was caused by muscular action alone.

EDWARD B. WESTON, M.D.

LEWISTON, MAINE, *Dec.* 20, 1875.

HEYWOOD SMITH'S SCISSORS.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—I have had recently put into my hand part of the number of your journal of Jan. 15th, 1874, and at pp. 45, 46, there is a description, with an engraving, of a pair of angular scissors, with double action, made to cut at any angle, by working on a hinge with a rotatory joint, and claimed to be introduced to the profession by Messrs. Tiemann & Co.

I beg to draw your attention to the fact that these scissors are my invention, and are fully described in *The Lancet* of April 27th, 1872.

I think it is but fair that when instrument-makers wish to put forward a new instrument they should give due credit to the inventor, even though he be not of their own country.

I remain, yours faithfully,

HEYWOOD SMITH, M.D.,

Physician to the Hospital for Women.

PORTUGAL STREET, LONDON, W., *Dec.* 3, 1875.

Medical Items and News.

NEW YORK ACADEMY OF MEDICINE.—At the recent meeting of this body, valuable donations to the library were announced. Notable among these were several volumes from Dr. J. T. Metcalf; 29 volumes, 110 miscellaneous medical journals, and 225 medical pamphlets from Dr. E. R. Peaslee; a magnificent donation from Dr. J. W. S. Gouley, consisting of the works of Hippocrates and Galen, in Greek and Latin, 13 volumes bound in 9 folios, and valued at 600 francs; an alphabetical index and catalogue of the first 73 volumes of the medical pamphlets in the library of the Academy, prepared and presented by Dr. Lawrence Johnson, and several volumes from Drs. E. D. Hudson, Jr., and J. W. Howe.

A bust of Dr. J. Kearney Rogers was accepted from Mr. Isaac F. Wood, and the thanks of the Academy tendered to the donor.

A portrait of Dr. John Watson was received from Mr. E. C. Watson, and a resolution of thanks adopted by the Academy.

The following resolution was reported from the Council and adopted by the Academy:

Resolved, That a committee of three be appointed whose duty it shall be to secure, if possible, the passage of a law that shall exempt the property of the Academy from taxation and seizure for debt.

The president appointed as such committee: Drs. Austin Flint, Sr., E. R. Peaslee, and J. O. Stone.

The president announced the death of Dr. John R. Van Kleek.

Dr. F. P. Foster then read a memorial, which was to have been read by Dr. Van Kleek upon the death of the late Dr. Isaac Wood.

After the reading of the memorial, Dr. A. C. Post reported the following resolutions upon the death of Dr. Van Kleek, and the president appointed Dr. James R. Wood as memorialist:

Resolved, That the Fellows of the Academy have heard with sincere regret the intelligence of the death of our old associate, John R. Van Kleek, M.D.

Resolved, That we cherish his memory as that of an honored and useful member of the medical profession.

Resolved, That we sympathize with the family in the great bereavement which they have sustained.

Resolved, That copies of the resolutions be sent to the family of the deceased and to the medical journals of this city.

A. C. POST, M.D.,
W. N. BLAKEMAN, M.D.,
J. G. ADAMS, M.D.

RECEPTION TO MEDICAL STUDENTS BY THE YOUNG MEN'S CHRISTIAN ASSOCIATION.—The Young Men's Christian Association gave a reception to the medical students attending the different colleges of this city, and extended to them the numerous privileges and advantages of the institution. A very large audience was present, composed chiefly of medical students and their lady friends. The programme was opened in the Hall by an organ selection, entitled "Thunder Storm," executed by Edward G. Jardine.

MR. WILLIAM E. DODGE, JR., the President of the Association, delivered the address of welcome, tendering the use of the hall, library, and gymnasium to the students attending medical lectures. In the course of his remarks he related some very interesting and telling anecdotes of professional life, and concluded by advising the students to cultivate a manly and Christian character. The address was followed by a song, "I dreamed that I dwelt in marble halls," rendered by Miss Benziger, after which the first speaker, Prof. FORDYCE BARKER, was introduced, and offered the following remarks:

MR. PRESIDENT:—On rising to perform the part assigned to me in the programme of the evening, it is my duty and my privilege to thank the Association, through you, for the kind and happy conception of this entertainment, which has been so beautifully carried out this evening. I thank you in behalf of the young gentlemen, your guests, who are present from every part of the United States and the British Dominion of North America, and who have come to this city on account of its great advantages for the study of our profession. I thank you, in behalf of their fathers and their mothers, their brothers, their sisters, and their sweethearts, that being strangers in a great city, you have held out the hand of friendly welcome to a social entertainment of music, song, and speech. I thank you, on the part of the faculties of the different medical colleges in the city, for your interest in and your hospitality to those who will hereafter represent in every part of the land the results of New York professional education.

As the magnificent organ performance, to which we have just had the pleasure of listening, recalls to my

mind the picturesque town of Freyburg, in Switzerland, with its striking view of the Alps and its suspension bridge, and also brings back to my mind's eye the beautiful Lake of Lucerne, its grand mountain scenery, with the Rhigi on the one side and Mt. Pilate on the other, and the wounded colossal lion of Thorwaldsen, an allegorical monument to the Swiss Guards of Louis XVI., because I heard this same piece played on the fine organs of Freyburg and Lucerne; so in after life a thunderstorm will recall to many a hard working doctor the reminiscence of the happy evening passed in this marble hall. I believe the hall is granite, but you will permit me to call it marble by courtesy for this evening only. The song which has just been so charmingly rendered will often be heard again by some of your guests in the households of the sunny South, the far West, and the frigid North, and will be sure to bring back the memory of earnest student life in New York, and the hospitable gathering in the Hall of the Young Men's Christian Association. I dare say that even to-morrow night more than one who is engaged in tracing out the muscles and the nerves, the veins and the arteries of the human body, will find himself unconsciously humming, "I dreamed that I dwelt in marble halls."

It is an ungracious act to criticise when everything has been arranged so well, but I must say to the students confidentially—I have often before talked to students confidentially—that it was a great mistake on the part of the committee of arrangements to put me in painful contrast with my friends and elegant (I meant to have said eloquent, but both terms are appropriate) confrères who are to follow, and who are noted for their gifts of oratory as well as for their rich, sonorous voices. Now, if I had only been set down for one of the songs, I am sure that I should have added much more to the entertainment.

Sidney Smith said that there would be many more Samaritans in the world were it not for the oil and the two-pence. The Young Men's Christian Association have proved themselves good Samaritans to the stranger students of medicine in this city, and have furnished the oil, or its equivalent gas, and the metaphorical two-pence. The pleasure they have given will remain a happy memory for after life. This programme will be taken home to many a household, and will be read with delight by many a fond father and loving mother. It sounds good, pure, and moral: "Reception to Medical Students by the Young Men's Christian Association of New York." The events of the evening will be rehearsed with glowing, grateful enthusiasm to the appreciative interested listeners of the home fireside.

And now having spoken my thanks in behalf of the medical students and of their friends and of the faculties of the medical colleges, will you, Mr. President, permit me to address a few words to your guests in behalf of the Association over which you preside.

Well then, gentlemen, students of medicine, I am authorized to express the hope of the Young Men's Christian Association that you may have the patience of Job, and a good many other patients, the piety of Abraham, the meekness of Moses, the strength of Samson, the valor of David, the wisdom and riches of Solomon, the zeal of Peter, the knowledge of Paul, and be like Luke a beloved physician, like him write a treatise, and after having lived to the age of Methusaleh, that you may, like Elijah, be taken up to heaven.

A violin solo by Carl Lanzer followed, after which

Prof. T. Gaillard Thomas, M.D., delivered another address, in the course of which he said, that in this broad land, teeming as it did with medical institutions, the number of physicians was necessarily rapidly increasing to meet the demands of an increasing population. Every one in this state of affairs admitted the urgent necessity of the maintenance of a good understanding between the medical guild and society at large. Then having given a brief history of the progress of medical science, he continued, by saying that in olden times, before society was so highly cultured as now, the medical student was looked upon as a rather wild, erratic, and dissipated individual, with an undue fondness for midnight raids upon neighboring church-yards. After a long course of social chastisements and reproofs, however, a change for the better had by slow degrees come over public sentiment, and had resulted in elevating the profession above the plane it occupied in former years. Although the character and social relations of the students had much improved, much yet remained to be done, and students themselves by their own efforts must elevate their profession and mutual interests.

After a pleasant song by Miss Benziger,

Prof. D. B. St. John Roosa, M.D., delivered an address, in the course of which he alluded to the great progress made in medical education during the past fifty years, claiming that New York was now entitled to the honor of being a university town, a medical centre for the United States. He concluded by saying that he interpreted the invitation extended to the students as a well-timed hint to them that it might be desirous for them not only to improve their morals, but their manners, which had become somewhat blunted by the professional experience of the lecture and dissecting rooms.

Chancellor Crosby, of the University, was called upon for a speech, but he begged to be excused, remarking that the statements he had recently made before the medical students had apparently so startled that body that he had not yet heard the last of them. After partaking of a collation the audience adjourned to the parlors, where they were further entertained by a musical programme.

Dancer's Cramp.—Dr. B. Schultz describes in a recent number of the *Wiener Med. Wochenschr.* a disease peculiar to solo dancers in the ballet, which has come under his observation in three cases, the most aggravated of which is described as follows: The patient complained of suffering very severe pains while dancing. Beginning in the soles of both feet the pains spread with increasing severity to the calves of the legs; they at last became so violent that her feeling of security was lost, the feet seeming as if made of wood. These pains were accompanied with violent palpitation; and, if she continued to dance, she felt faint and sometimes lost consciousness, the body becoming quite rigid. When the pain and palpitation were less intense, the pain continued after dancing, and ceased very gradually, leaving some tenderness of the soles; on attempting again to dance the suffering would recur again. Dr. Schultz found, from the examination of these cases, that the cause of the pain lay in the *pas* performed on the points of the feet, and is owing to exhaustion of the muscles which fix the metatarsus and phalanges of the great toe. The shoe worn by the dancer, without which the ballet step seems to be impossible, is made as follows: The dancing shoe is made rather wide; the sole is of soft leather, and shorter than the foot, reaching only as far as the posterior third of the ungual phalanx of the great toe. The upper part, generally of satin, projects forward, and supplies the place of the deficient leather of the

sole. This part of the satin is worked threads, so that it may not be torn. In the interior of the shoe, over the leather sole, is a layer of thin, firmly pressed pasteboard, either extending over the whole breadth of the anterior part, or limited to the length of the great toe. In the former case it is carried back, gradually narrowed as far as the heel. The leather sole and its covering are lined with find kid leather. The heel part of the shoe is quite soft, consisting only of satin; and the shoe is fastened above the ankle by narrow ribbons. Without this preparation the pointed step is impossible.

New York Pathological Society.—At the last annual meeting, held January 12, 1876, the following officers were elected for the ensuing year: President, C. K. Briddon; Vice-President, Dr. R. F. Weir; Secretary, Dr. George F. Shrady; Treasurer, Dr. John H. Hinton.

State Emigrant Asylum of Ward's Island.—Concerts are given to the patients of this institution every month by volunteer performers.

Small-Pox in Brooklyn.—The Brooklyn Board of Health have considered it necessary to divide the city into small-pox districts, over which a physician is to be placed, whose duty it is to arrest and prevent the spread of the disease by every means in his power. Dr. D. H. Cronin is chief of the staff.

Irregular Practice in Bavaria.—A ministerial order, dated July, 1873, provides that, before the 1st of March in each year, a tabular return shall be made of persons practising medicine without due authority in the kingdom of Bavaria. The table for the present year is published in a recent number of the *Aerztliches Intelligenz-Blatt*. It shows that there were, on January 1st, 1,156 illegal practitioners—911 men and 245 women—in the kingdom; and gives statistics as to the nationality, social condition, and calling of the various persons, and the department in which they practise. There are 106 homœopaths—99 males and 7 females; 39 bone-setters—28 males and 11 females; 15 rheumatism and gout doctors; 2 hydropaths; while 4 gave their special attention to skin-diseases, 2 to cancer, 2 to syphilis, 7 to hernia, 4 to whitlow, 1 to toothache, etc., and in the list are 396 *chirurgen*, barber-surgeons and dentists, and 40 apothecaries. Medicine in general is practised by 464; internal medicine by 112; and surgery by 50.

Vaccination in St. Petersburg.—In the Foundling Hospital at St. Petersburg, where most of the public vaccination is carried on, calf lymph has been used side by side with human lymph for five or six years past. It is found to be equally protective, and failures in primary operations have, by care and perseverance, been reduced as low as two per cent.

A New Weekly.—*The Louisville Medical News*, a weekly journal of medicine and surgery, is edited by Richard O. Cowling, A.M., M.D., Professor of Surgical Pathology and Operative Surgery in the University of Louisville, Ky., and William H. Galt, M.D. Terms, $2.10 per annum in advance, postage paid.

A Spiritual Physician recently gave the following opinion, based on the examination of a lock of the patient's hair: "There is a bilious torpid state of the liver, an over-secretion of gall fluid. This mingles with the bile and leaks into the stomach, upon which is fever-coating. This retards digestion and agitates the nervous system. Too much internal slow fever habit, obstructions at the kidneys, sediment in the bladder."

Another Giant.—The *Pabillon Medico*, of Nov. 21, quotes from *La Correspondencia* the statement that a young man from Alcocer, twenty-six years of age, and 2.80 metres (9 ft. 2¼ in.) in height, named Augustin Lorenzo Capilla, has been presented to his majesty the King of Spain.

The Late Dr. John R. Van Kleek.—At the monthly meeting of the Board of Trustees of the Physicians' Mutual Aid Society, held at No. 12 W. 31st St., January 4th, 1876, the death of our late associate, Dr. John R. Van Kleek, having been announced to the meeting, it was, on motion,

Resolved, That a committee of three be appointed to draft resolutions in reference to the same.

The Chair appointed Drs. Barry, Gouley, and Vandervoort as this committee, who subsequently presented the following resolutions:

Resolved, That the sudden death of Dr. John R. Van Kleek has deprived the Board of Trustees and the Society of one of its most steadfast and efficient members, whose deep interest in its welfare and usefulness was at all times manifested by his regular attendance at our meetings, and in the share he took in all its deliberations.

Resolved, That the Board of Trustees, in common with those Societies of which he was an honored member, deeply deplore the loss they have sustained, and present to the family of the deceased their sympathy and heartfelt sorrow in this their hour of trial.

Resolved, That a copy of the above resolutions, signed by the President and Secretary, be transmitted to the family of the deceased.

Mark Blumenthal, M.D., *President*.
Frank P. Foster, M.D., *Secretary*.

The Deanship of the Faculty of Medicine in Paris has at last been accepted by Professor Vulpian. Professors Broca and Sappey are spoken of as the assessors to be appointed.

Registrars as Agents for Quack Infant Medicine Vendors.—The proprietors of an English quack medicine, which is widely advertised to afford instant relief in convulsions, flatulency, affections of the bowels, difficult teething, thrush, rickets, measles, whooping-cough, or vaccine inoculation, and rejoices in the name of "Infants' Preservative," have recently adopted a new method to push their nostrum. A circular has been addressed to every registrar of births and deaths in England and Wales, offering to pay him for delivering a circular advertisement of this nostrum, together with the vaccination notice at the registration of every birth. As there are 2,193 registrars in all in the districts named, it is probable that the project will be a paying one, although a considerable number may decline to become the agents of the scheme.

Is Cowpox Preventive of Foot-and-Mouth Disease.—M. Felizet, of Elbeuf, has observed that, while epidemics of cowpox and foot-and-mouth disease have been prevalent simultaneously in his vicinity, no beast affected with cowpox has, up to this date, been attacked with foot-and-mouth disease. Following out this observation, M. Felizet has, during the last four months, vaccinated thirty oxen, and not one of the twenty-five beasts effectually inoculated has, up to this date, shown any sign of foot-and-mouth disease, although living among animals infected largely with it. M. Felizet communicates this observation to the *Recueil de Médecine Vétérinaire*, the editor of which, M. Bouley, suggests that in order to ascertain if cowpox is preservative against this disease the experiment should be reversed, and animals which have had the foot-and-mouth disease should be vaccinated.

Original Lecture.

UNUSUAL UTERINE HEMORRHAGES.

BEING REMARKS MADE BEFORE THE NEW YORK ACADEMY OF MEDICINE, JANUARY 20, 1876, ON A PAPER READ BY DR. H. T. HANKS, "ON THE CAUSES AND TREATMENT OF CASES OF UNUSUAL UTERINE HEMORRHAGES."

By FORDYCE BARKER, M.D.

Mr. President and Gentlemen:—The subject now before the Academy for discussion is one of great importance and interest, and one which every practitioner must fully understand, because it constitutes a prominent symptom in a large class of cases.

The paper to which we have listened this evening is a conscientious study of this subject, and does its author credit; but the subject is so large that no single paper, of reasonable length, can embrace all the topics which it involves.

Menorrhagia and metrorrhagia are either active or passive. They are active where dependent upon rupture of blood-vessels occurring in connection with excessive fluxion of blood towards the uterus. Passive menorrhagias and metrorrhagias are those which occur not only from excessive determination of blood towards the uterus, but are associated with a depraved condition of the blood, or a weakened condition of the blood-vessels of the part, or impeded return of the venous blood.

In studying the causes of menorrhagia and metrorrhagia, we have first to notice the essential condition of the pelvic organs associated with the function of menstruation. Those cases which depend upon some peculiar condition affecting the uterus itself have been fully discussed in the paper read by Dr. Hanks, and I do not, therefore, propose to go over that portion of the subject. Of the conditions which give rise to active hemorrhage from the uterus, there is only one which has not been alluded to by the author of this paper; nor do we find any special reference made to it by writers upon diseases of women, namely, a hyperæmic condition of the organ dependent upon perimetric exudation. In some of these cases, the uterus is bound down by exudative adhesions, hyperæmia results in consequence of an impeded return of the circulation, and at the time of the physiological congestion of the menstrual period, menorrhagia is a result.

There is a class of cases in which uterine hemorrhage occurs independently of any peculiar condition of the uterus itself.

Certain conditions of the ovaries may give rise to an unusual discharge of blood from the uterine cavity.

Acute ovaritis is one of these conditions; and although very rare in the non-puerperal woman, yet under the influence of strong sexual excitement, or by some sudden shock, emotional or physical, the process of ovulation is arrested, acute ovaritis is excited, an increased fluxion of blood towards the uterus is developed, and profuse hemorrhage may follow.

Ovarian dysmenorrhœa is another condition which is sometimes attended by profuse uterine hemorrhage, although deficient menstrual discharge is more frequent. There is what has been termed the ovarian temperament, a condition in which the ovarian function is very active, fully completed, while the uterine function and development are correspondingly imperfect.

This class of cases is characterized by the early appearance of menstruation, by an excitable nervous temperament, a tendency to hysteria; and when menstruation is to appear, the function will be preceded for two or three days, or even more, by languor, nausea, headache, pains in the breast, and frequently by severe pains in the region of the ovaries; and when at last the menstrual discharge appears, in a certain although not large percentage of cases it is apt to be excessive. These cases of ovarian dysmenorrhœa and menorrhagia are not very rare. In some instances great benefit is derived from the use of bromide of potassium administered in free doses for a few days previous to the occurrence of menstruation; and to this may be added leeching at the commencement of the ovarian symptoms. Of course the woman should maintain the most perfect quiet and rest in the recumbent posture during the entire time occupied by each menstrual epoch. Sometimes the shock developed in this class of cases will be such as to require an entirely opposite course of treatment.

Here again the plan to be pursued is determined by the general condition of the system, and if there is a depressed condition present, it must be met by the use of those agents so well recognized as being proper and important in the treatment of shock and depression under any circumstances.

Both plethoric and anæmic conditions of the system are found associated with ovarian dysmenorrhœa and menorrhagia.

Acute ovarian displacements, such as a sudden prolapsus of an ovary from violent effort, or shock, or produced by constipation, may give rise to menorrhagia, as a result of the highly congested ovary.

When this accident occurs it will be attended by acute symptoms of displacement of the ovary; and the patient suffers greatly from the characteristic pains which attend this displacement, and the condition may be accompanied by menorrhagia extending over two or three menstrual periods. As a matter of course, the rational method of treatment under these circumstances is to overcome the displacement and the ovarian congestion.

There is another class of cases in which both menorrhagia and metrorrhagia occur, which are due to *conditions of organs remote from the uterus*, or constitutional causes, if you choose to call them such.

Profuse hemorrhage from the uterus may result from obstructed portal circulation, obstructed circulation through the right cavities of the heart, and also from certain diseases of the kidneys.

Disturbed brain action from emotional causes may be followed by violent uterine hemorrhage. Such cases must have fallen under the clinical observation of most who have been long in practice, which are entirely unassociated with any evidence of local affections of the uterus.

Again, we have constitutional causes of uterine hemorrhage, which may be regarded as *toxic*.

Malaria is not unfrequently the cause of menorrhagia, not always profuse, but the menstrual flow is prolonged unduly by the general impairment of the constitution and the defective nutrition of the blood vessels of the uterus from the continued influence of malaria.

Menorrhagia may be caused by the toxic influence of various exanthemata. A most remarkable case of menorrhagia once came under my observation, and occurred in the person of a girl, æt. 11 years, the daughter of a member of this Academy, who was suffering

from measles. The exhaustion present in that case was equal to anything I ever saw in the adult female, having profuse uterine hemorrhage from any other cause. It was finally arrested, after a great variety of measures adopted had failed, by the introduction of an alum cone into the cervix. This is the only case I have ever seen in connection with measles.

I have seen four cases of this character occurring in patients sick with scarlet fever. It is also said to occur with typhoid fever, small-pox, yellow fever, etc.; but associated with these latter, menorrhagia has never fallen under my observation.

There is another class of cases in which excessive uterine hemorrhage occurs, dependent upon a *constitutional cause somewhat peculiar*. Perhaps I am wrong in classing these cases under a constitutional head; but the class of cases to which I refer may be described as follows:

A woman who has been free from any uterine disease, perhaps has borne one or two children, suddenly begins to grow stout; exhibits a remarkable tendency to obesity; so that from being a thin, spare woman, she increases in weight from fifteen to fifty pounds, or even more, and with this remarkable tendency to obesity there is in some cases a rapid diminution in the amount of blood lost at each menstrual period.

But there are other cases belonging to the same class, where, instead of diminution in the menstrual discharge, this tendency to obesity is accompanied by an excessive uterine hemorrhage.

These are troublesome cases, for the reason that you will suspect, from the severity of the flow, some serious uterine lesion; but when you come to make the most careful examination you will be rewarded by a failure to detect any condition which will satisfactorily explain the occurrence of the hemorrhage.

The only thing which does explain the hemorrhage in these cases is the increased size and consequent plethora of the uterus.

I think this class of cases is not very rare. I have repeatedly examined the internal surface of the uterus, after dilating the cervix with compressed sponge, in these cases, feeling certain that I should find some uterine disease which would account for the profuse flow, but have been disappointed in the same number of cases by finding it entirely free from any lesion or disease appreciable or discoverable by the most careful examination. The appearance of these patients is usually healthy, and the countenance is commonly flushed, but at the same time they are anæmic. The blood is impoverished, and the patient has a flushed face simply because the capillaries upon the surface, which are not large enough to allow blood of a normal character to pass through them, now carry red anæmic blood, and the slightest emotion or exercise causes them to be surcharged and the face to become flushed. They are cases of anæmia, and when placed upon the use of tonics, quinine, iron, chlorate of potassa, etc., instead of getting stouter and increasing in weight, they will diminish in size and weight, while the patient is greatly improved in health and strength. It has seemed to me also that there are certain moral phenomena peculiar to this class of cases, for these patients almost invariably believe that they are suffering from some disease of the heart. They are especially liable to attacks of palpitation, and a very frequent complaint will be that they have awakened in the night and found that the heart has stopped beating.

The plan of treatment which I adopt for these cases is first to administer the acetate of ammonia and saline cathartics for the purpose of depleting the blood of its excess of watery elements. Next I use chlorate of potash as an agent of very great value, on account of the influence it has in changing the condition of the blood; and then come the preparations of iron.

In immediate association with this class of cases comes another form of menorrhagia, namely, *chlorotic menorrhagia*. We may have chlorotic menorrhagia as well as chlorotic amenorrhœa, although it is not of such frequent occurrence. These cases, however, are sufficiently frequent to be met with by any man with an ordinary amount of practice.

Another class of cases, which every practitioner must constantly come in contact with, is *menorrhagia associated with the climacteric period*. These form a class of troublesome cases. For some reason the menstrual function becomes more active than natural, and is sometimes prolonged as to duration, and abnormal as to frequency of recurrence. Many of these cases occur in women who, at the period of the menopause, have a tendency to become much more corpulent than in former life, and in some such the menorrhagia may be conservative in relieving dangerous plethora, but it is by no means confined to this class. It is also seen in the thin and spare. When it occurs it usually excites great apprehension in the mind of the patient, for, with a great majority of women, the belief is strong that the time of the menopause is the time of all others most favorable for the development of malignant disease of the uterus which will destroy their lives.

And it is only natural that we should expect to find some uterine lesion present, when we take into consideration the changes which this organ has undergone during a series of years. The mucous membrane has been constantly undergoing change, sometimes in the full development of the decidua of pregnancy, and certainly in the formation of the menstrual decidua. It is not surprising, then, that at this period a recurring physiological congestion should in some cases become a chronic engorgement, and arrest the incessant metamorphosis of the internal surface of the organ, which has been going on for thirty years or more, and thus result in some lesion of this surface.

In closing, I will briefly refer to the plan of treatment which I adopt in this class of cases. Where the uterus is found to be increased in size and weight, I direct the patient to use, for a week previous to the return of the expected period, suppositories made after the following formula:

℞. Ext. ergot. aq. (Squibb's)..... ℥ij.
Cacao butter..... ʒ i.
M.
Div. into suppositories No. xii.

One of these suppositories is to be introduced into the rectum morning, noon, and night; and I always give positive directions that they shall be carried far up into the bowel, and the patient must keep the recumbent posture for at least one hour. These are to be continued for a week previous to menstruation, and also throughout its duration. I prefer to use ergot in this manner, rather than by the hypodermic syringe, for the reason that the remedy is easily handled by the patient or nurse, and you avoid the risk of troublesome abscesses in the tegumentary walls of the abdomen, which in my hands have frequently followed the use of the ergot by the hypodermic syringe.

Now, if the hemorrhage is prolonged, although not excessive, I infer that there is some lesion affecting the lining membrane of the uterus.

I then have resorted to another plan of treatment, which, since I commenced it, I have rarely found neces-

sary to repeat in any case beyond the second menstrual return.

In those cases, therefore, of irregular uterine hemorrhage seen in connection with the climacteric period, sometimes prolonged, sometimes profuse, I introduce into the cavity of the uterus cylinders of iodoform made according to the following formula:

℞. Iodoform ..... ʒ jiss.
Gum tragacanth ..... gr. xv.
Mucil. ..... q. s.
M.

Div. into cylinders No. x., each one and one-half inches in length.

One of these cylinders is to be carried completely into the cavity of the uterus, and a pledget of cotton introduced against the cervix to retain it in position. Introduce one of these cylinders daily for five or six days previous to menstruation.

The only objection to them is the excessively disagreeable odor which attends their use.

I have frequently had patients complain of a most disgusting taste in the mouth, in less than two minutes after one of these cylinders had been introduced into the cavity of the uterus. But to me, the results which have followed their use have been most satisfactory. These cases of climacteric hemorrhage are quite common, and are often found very troublesome to the practitioner. By the use of the suppositories of Squibb's aqueous extract of ergot, the chronic engorgement of the uterus may generally be effectually overcome. If the menorrhagia still persists, we have good reason for suspecting lesion of the internal surface of the uterus, which I think is cicatrized by the cylinders of iodoform. I have formerly used for this purpose sulphate of zinc, introduced into the cavity of the uterus, and in some cases of profuse hemorrhage the solution of the persulphate of iron; but, in all those cases in which the cylinders of iodoform have been used for some days previous to the appearance of the flow, there has been subsequently no hemorrhage of sufficient importance to make the solution of the persulphate necessary.

I have sometimes found it necessary to use the suppositories at each recurring period for several months, as the tendency to engorgement of the uterus is very difficult to overcome at the period of the menopause.

Short-sightedness in France.—The number of short-sighted persons in France is said to be steadily on the increase; and as this condition would constitute a serious inconvenience in a military point of view, the authorities have become anxious about the matter, and have requested the Academy of Medicine to investigate the cause, and, if possible, to remedy the evil. The subject has been lately discussed by the Academy, but the conclusions arrived at are not yet known, but it would not be surprising if the use of spectacles should be introduced in the army. Hitherto only officers have been allowed to wear spectacles, but the privilege will have to be extended to the soldiers in the ranks if it be desired to muster a strong army, particularly as it has been discovered that, in many cases, myopia is artificially produced in order to escape the conscription. This is done by reading with strong concave glasses, so graduated as to reduce the visual power to the use of the No. 2 or 3 glasses.

Dr. E. P. Willett, the chief of a gang of body-snatchers, who was recently captured, pleaded guilty in the Criminal Court of Chicago, Jan. 25. He was charged with robbing the grave of a mother and child in Graceland Cemetery a few months ago.

Original Communications.

DIVULSION OF URETHRAL STRICTURE, FOLLOWED BY COPIOUS HEMORRHAGE AT THE END OF A WEEK.

By M. A. WILSON, M.D.,

late surgeon to city work-house and district physician to the out door poor, cinn.; late attending physician to new york, north western, and bellevue dispensaries, member county medical society, etc

I report the following case, for the reason that I have been unable to find any record of a similar one.

I have also inquired of a number of my medical acquaintances in this city, some of them prominent specialists in this department, none of whom could direct me where to find recorded a like one, in fact saying that they had never heard of such a case. Hemorrhage from the urethra (I refer exclusively to that consequent upon surgical procedures), is quite common, and occurs frequently as a result of the passage of sounds, bougies, or catheters, internal urethrotomy, single or otherwise, or any other traumatic injury to the urethra.

Hemorrhage after urethrotomy may be immediate or secondary; the latter form occurring in only a limited number of cases, possibly within twenty-four hours, or not until after the lapse of ten or twelve days; but it is rare, and to be regarded as a consequence of unskillful operating.

In connection with, or immediately following divulsion, a few drops of blood escape, which are not of any moment; it rather indicates that the divulsor "has done its work," and that the stricture-tissue has been ruptured. But a secondary *copious* hemorrhage, following the simple, rapid operation of divulsion, occurring eight days afterwards, in a strong, healthy man, no other existing complications, without any recognizable cause, is, as I have just said, an accident not yet mentioned by any writer that I am aware of.

Captain S., æt. 32, strong, rather stout, weight about 175 lbs., called upon me July 24th, 1875; had been in U.S.A. (cavalry service) since 1861, with the exception of last two years, and had suffered at one time for three months from intermittent fever; remainder of the time "perfectly well;" never contracted syphilis. Has had gonorrhœa three times, the first in 1863, lasting eight months; the others of short duration, during one of which epididymitis of the right testicle was developed. In the winter of 1873–4 he was treated for urethral stricture by an army surgeon, but he does not recollect which instrument and number the doctor *began* with; thinks the treatment ended when he reached No. 12 E. steel sound.

The treatment was interrupted by another attack of epididymitis, right side, upon subsidence of which the testicle was strapped and use of sounds continued.

In the early part of June, 1875, he again observed a slight urethral muco-purulent discharge, not accompanied with "ardor urinæ" or acute inflammation, but he did not know whether he had contracted a fresh gonorrhœa or not.

From that time until his call upon me (July 24th) he had been treating himself, using pure claret as an injection, and taking internally *his* prescription, a mixture of copaiba, tr. aloes, and spts. nitr. dulc. He was not, however, very successful, and requested me to treat him for "gleet."

Making it an invariable rule in patients with such histories to carefully examine the urethra, I at once did so in this case.

First picking up a No. 4 (English) flexible bougie, I found it to pass with difficulty. A bougie-à-boule, smaller size, was then introduced, which located the stricture (but one) in the membranous urethra, one-half an inch in length, very firm.

I then passed a filiform guide into the bladder, and upon it a No. 4 tunneled sound, which, upon withdrawal, I endeavored to follow with a No. 5 or 6 flexible bougie; but the stricture seemed so resisting and dense that they only bent sharply upon themselves, and I did not succeed. His urethra being very sensitive, and a slight bleeding taking place, I desisted entirely that day (Saturday), and requested him to come again Monday following.

At this visit it seemed impossible to make further progress towards a cure "by dilatation," either with flexible or inflexible instruments of any kind, and I at once advised "divulsion," especially as he was hurried for time to attend to important business in Boston, go to Europe, and quickly return to the south.

Besides, the urethral canal was very irritable; these few introductions of instruments had rendered it very sensitive, causing quite an amount of pain, and always accompanied by slight bleeding, however gently and carefully made.

On the following Wednesday P.M., July 28, 1875, with the kind assistance of Prof. E. L. Keyes (Dr. R. W. Taylor was also present), I ruptured the stricture with Sir Henry Thompson's divulsor to a point of dilatation equal to a No. 20 E. sound. But few drops of blood followed, very little pain was felt, no anæsthetic employed. After withdrawal of the divulsor the meatus was incised, and a No. 16 sound passed readily through the old site of stricture into the bladder.

A hypodermic injection of a quarter of a grain of morphia and ten grains of quinine were then administered, and the patient sent home in a carriage.

I should mention that before the operation the right epididymis was slightly tender upon pressure, somewhat indurated, but not swollen, for which condition a suspensory bandage was advised, in conjunction with rest and quietude. Beyond granular effervescent potass. bicarb., to render the urine less irritating, ten grains in water three times daily, nothing else was prescribed.

As he had very little business in New York to attend to, he remained almost constantly in his room and in bed; his bowels regular, urination occasioning him no pain nor difficulty whatever.

He felt perfectly well (no complications whatever arising) until the night of the same day as the operation, one week afterwards, I was at twelve o'clock hastily summoned to his bedside, and found to my astonishment that he had, within twenty-five minutes, lost at least from one to one and a half pints of blood per urethra (judging from the saturated bed-clothes, towels, etc.), clear, fresh, red, and still flowing freely when I arrived. He was pale, and much alarmed; had enveloped the genitals with cold, wet towels without effect. I at once employed ice freely, placing it upon and about the penis, scrotum, perinæum, pubis, in the rectum, and gave a teaspoonful of fluid extract of ergot. These measures producing no marked effect, I passed a No. 14 sound, which promptly checked the flow, except a very slight oozing from the meatus.

Giving him a half drachm each of fl. ext. ergot and laudanum, placing towels and cloths firmly against the perinæum, leaving the sound still within the urethra, directing a friend of his (who consented to remain with him all night) to continue the ice in moderation, with a teasponful of the ergot every two hours, I left him.

I of course thought of injecting the urethra with persulphate of iron, etc., but as the sound, pressure upon the perinæum, ice, etc., seemed to control it (by forming, I suppose, a urethral clot or clots), I considered that measure unnecessary.

Returning next morning at seven o'clock, learned that he had slept very well, had taken two doses of ergot, but of course did not feel particularly comfortable.

The blood had coagulated upon the sound at the meatus, to the extent probably of half an inch in depth, merely from the "oozing."

As he wished very much to urinate, I withdrew it without difficulty, causing no pain, nor did urination; but, as I feared, the movements necessary to this act, together with the removal of the sound, pressure, and ice, brought on again an active fresh hemorrhage.

For the time being I placed a folded dry towel upon the end of my cane, and pressed it against the perinæum, just at the location of the stricture, the other end touching the footboard, and had him "push himself" against it, regulating the pressure according to the pain or his own feelings.

This procedure answered so well that I had his friend procure a stick about three inches wide and three or four feet long, which I substituted for the cane, occasioning him no discomfort whatever. Discontinuing the ergot and ice, I prescribed fifteen drops of liq. ferri perchlor. in simple syrup and cinnamon water every hour, also one grain of opium with two of acetate of lead every three hours; directed him to remain quietly in bed, to eat any light food he might fancy, and not to micturate until I returned.

At next visit, four o'clock that afternoon, there was but the faintest trace of fresh blood at the meatus, although he had for last hour or two lessened the perineal pressure very greatly by drawing himself away from the stick somewhat. During and after urinating there was no appearance of fresh blood, and I removed the pressure (stick) entirely.

Would have injected the urethra had it been necessary.

Continued the iron internally, stopped the pills. I called at eleven that P.M.; patient very comfortable, had had a good appetite, was in good spirits.

He again urinated freely and easily, no blood to be seen. Expressing a desire to have his bowels move, I advised that any such immediate attempt be postponed until I should see him again.

The next morning he seemed "as well as ever," and all treatment was discontinued.

He remained quietly in his room for a day or so, and on the sixth day after the hemorrhage, twelfth after divulsion, Nos. 16 and 17 steel sounds were passed without difficulty or pain.

Notwithstanding the ice, hemorrhage, recumbent position, suspensory bandage, rest, etc., the right epididymis was still about as sensitive and tender as at first.

I advised the bandage to be worn constantly, and for him to remain quietly in the hotel. He "drank" very little at any time, "nothing" since first call upon me.

August 12th. Introduced Nos. 17 and 18, and on August 14th the same; not employing a larger sound than No. 18, for the reason that he expected hourly almost to leave the city, intending to continue the treatment after his return.

Five grains of quinine were administered after each introduction, as a prophylactic against urethral fever.

The meatus was again incised, owing to the pain caused by the sound at that point.

August 15th. Wishing to go east for a few days, he requested further advice relative to his "sore testicles," for the *left* epididymis was now slightly tender and indurated, it having also been injured, he said, against the pommel of a saddle while riding some years ago. I prescribed the following: R. Plumbi iodid. grs. xii., ungt. stramonii ℥ i. M. S. portion the size of a hazel-nut to be rubbed into the scrotum night and morning; a like amount to be spread over a piece of rag or lint, laid upon the scrotum, covered with oil-silk to prevent evaporation, etc., the suspensory bandage to enclose all. Internally, R. Potass. iodid. ℥ i. ext. conii mac. ℈ ɔ., syr. sarsæ co. ℥ ij., aquæ dest. ℥ iv. M. S. a tablespoonful three times daily.

Within a day or two he sailed for Europe; has not since returned, nor have I heard from him.

There are several points of interest in connection with this case, one of which is its rarity; for it may be that I have not been sufficiently thorough in my search through the literature of the subject, and some cases *may* have been reported.

Considering, also, that such hemorrhage has not come within the experience of the above-mentioned surgeons and others of this city, I feel justified in alluding to its rarity.

In the next place, the obscurity of the origin and cause of such a *free* hemorrhage, notwithstanding the almost perfect conditions and hygienic surroundings of this patient, for the whole week subsequent to the operation. A man of wealth, with no business cares nor anxieties, taking no exercise, lying in bed almost constantly in one of our best hotels, with good attendance; drinking no spiritous liquors whatever, eating plain food; no hemorrhagic diathesis; health excellent, no sexual intercourse, venereal excitement, erections or chordee, regarding all of which I made special inquiry.

The exact condition producing hemorrhage under such circumstances can of course only be surmised; had there been any cutting (urethrotomy), we might more naturally have expected such a sequence.

Ulceration, as the result of the violence or injury inflicted upon the mucous membrane or other tissues at the strictured point, and proceeding so far as to cause the opening of a small blood-vessel at that point, would easily account for it; and this I believe to be the explanation of the accident, although the discharge after continued the same as before the operation—slight, gleety, neither profuse nor purulent—nor did he complain of any tenderness or soreness along the urethra, two features or symptoms we would rather expect to find accompanying an ulceration so extensive as to open a blood-vessel. Again, for so thorough a lesion as this (if it did exist), it healed remarkably well and quickly; for no sounds were passed nor any treatment employed for nearly a week after the bleeding (nothing to indicate ulceration during this time), and *then* only the introduction of sounds seventeen and eighteen three times before his departure for Europe.

In conclusion, this case proves that the operation of divulsion *alone*, and only upon *one* stricture, although so simple and readily performed, however gently and carefully done, *may* be followed by hemorrhage sufficiently serious to alarm and debilitate the patient and to demand of the surgeon prompt and energetic measures for its control.

12 East Twenty-Eighth Street.

THE IMPENDING DANGER.

By J. B. MATTISON, M.D.,

Brooklyn, N. Y.

America is in peril of becoming a nation of opium inebriates. Tens of thousands of hapless devotees bow at the shrine of this seductive goddess, and, from the palace and the poorhouse, the hall and the hovel, is being recruited the increasing host marching downward, with steps, slow but sure, to death or degradation.

That this seemingly sensational statement is not exaggerated, can be proven by statistics and by the assertions of those who, with abundant opportunities for observation, have not failed to note the gradually accumulating evidence of this fact, sad though it be.

From one of, if not *the* leading exponent on the subject of alcoholic and opium intoxication in this country, we have authority for the statement that while the *former* is *diminishing*, the *latter*, undoubtedly, is on the *increase*. Dealers in crude opium, and manufacturers of its alkaloids, assure us that the importation of the one and the production of the other are rising rapidly, year by year; so much so regarding morphia, that, at one of our largest manufacturing centres, the supply is said to be insufficient for the demand.

Accepting these statements as true—and we have no proof to the contrary—the question naturally presents itself, What becomes of the vast amount of this powerful drug? Of the sources of its consumption there are but two: the one, its employment as a therapeutical measure; the other, as a stimulant. Regarding these, the assertion has gone the round of the press, medical and non-medical, that, in the opinion of those competent to judge, not more than one-third is for the former purpose.

Allowing this, the query rises, What is the *fons et origo* of the inordinate demand as a stimulant? Is the initial point of its taking merely the desire for its pleasures, physical and psychical. Or is it, that, once ordered on professional authority for some ill, fancied or real, and continued for a time indefinite, the unfortunate victim, all unconscious of the danger towards which he is drifting, finds himself, when therapeutical necessity for its use has been fulfilled, in the coils of a monster whose subtle power and strong embraces only he that feels them knows?

Touching this point, observation varies, though we think it indisputable that the vast preponderance of testimony favors the cause last mentioned as the primal source of this most deplorable practice. Dr. Geo. Conners, who has lately written upon this subject, holds to the opposite view, his language being, "in accordance with the best information I have been able to gather, the largest number of opium eaters contract the habit from choice, merely for the pleasures of opium."

Foremost among those qualified, from long experience and careful observation, to pass judgment on this question is Dr. Jos. Parrish, for several years President American Association for the Cure of Inebriates, who, summarizing certain facts to be deduced from a most interesting and instructive address delivered before that organization, reaches a directly contrary conclusion, and says, "Men take it, not for social enjoyment, but for a physical necessity."

A prominent physician in this State has written us that, to his knowledge, of more than a half score of opium inebriates who reside in proximity to his office, nearly all assert the inception of their baneful bondage was a prescription containing opium, in one form or another, at the hands of their medical attendants.

One truly commiserable victim, now running under a steady pressure of twelve grains of morphia *per diem*, dates this "horror of a great darkness" resting upon him, to the order of his physician, given years before, to take it for the relief of a pain in the back!

A leading practitioner in a city not far distant recently informed us, that he was assured more than twenty cases of this kind were within the cognizance of one of his professional friends, most of whom dated their durance to an opiate prescription.

Dr. Brinton, in a recent editorial on this topic, asserts that "more than one such instance has occurred to our personal knowledge," and takes decided ground against an indiscriminate prescribing.

From across the ocean come the notes of alarm, Dr. Francis W. Mirnett, Lecturer on Materia Medica at Surgeons' Hall, Edinburgh, being impelled to raise a warning voice on account of three cases of the opium habit coming under his observation within a limited time, and all having their starting-point in a physician's prescription. After detailing them, he remarks as follows, all of which is to be commended to the careful consideration of every practitioner; "This leads me to say that I think there are many cases of chronic disease, or disease in which sleeplessness is a prominent symptom, in which opium is frequently prescribed, without, perhaps, any thought of this danger supervening, and which has led me to believe and practise that it is advisable not to give opium continuously, for any length of time, in those cases, unless in painful and incurable diseases, as cancer, etc., especially if the patient is of a nervous temperament. There is no doubt that pain or sleeplessness, would more frequently have to be endured, but other remedies might be substituted, which would in part, though not entirely, take its place. And if we consider that it would save some, more, perhaps, than many are aware of, from contracting such a habit, I think that, at least, it would be advisable to consider this danger, and bear it in mind, when we are called upon to treat such cases, and believe opium to be indicated; a danger which most readers well know, from their own experience, not to be a fanciful one.

"Medical men are nowadays occasionally assailed with reproach for prescribing stimulants rashly and unnecessarily, and so encouraging a taste for them; but the public are already beginning to find out that, as a rule, if individuals want stimulants, they do not wait to get the sanction of their medical attendant, although they may, and do sometimes, use his name as an excuse.

"But it is otherwise with those whom I have mentioned, who have not known the potency of the drug, at least personally, until it was professionally administered, and who, in all likelihood, would not have known it unless so ordered. And this is generally the rule, I think, that the majority of habitual opium-eaters have, in the first instance, acquired the taste for it after having been ordered it by a medical man; not that I think it by any means a reproach to us, or that we should be afraid to use it on account of the fact that some ill-regulated people will abuse the drug to their own hurt, but for the reason I have mentioned: and in view of this danger, I venture to say that this ought to be borne in mind when we administer opium in these cases, lest we might be the innocent cause of setting the spark to the fire that may only be extinguished with life."

Speaking from personal knowledge and observation, the entire weight of our testimony militates the statement that this direful degradation is induced voluntarily. In a remarkable instance presented the profession the past year—*vide* RECORD, May 1—nearly seven years' servitude, starting in a surgeon's selection of morphia for the relief of a severe sciatica, was endured before the poor bondman came out into perfect freedom.

A lady in one of the New England States, of high culture and eminent social position, fell a victim after only eight weeks' daily use of the hypodermic syringe, and underwent ten days' torture of mind and body ere was broken the last link of the chain that had been unwittingly forged around her.

A lady in this State, after three months' employment of morphia in moderate daily doses, per physician's prescription, awoke to the consciousness that she was in the coils of this monster, and we have yet to learn of her escape.

An intelligent physician of this city, after a few weeks' using of this drug for a severe neuralgia, found himself "in the bonds," and though many months have lapsed he is still enthralled. More cases, all confirmatory, could be cited, but they are unneeded.

Granting the foregoing statements their proper consideration, what is the great lesson to be learned on this all-important subject? Simply this, that the *necessity* for caution in the prescribing of opiates rises to that of a *duty* in view of the fact, incontestable we take it, that much the larger number of pitiable victims to this galling bondage become such through the unintentional ministrations of their medical attendants.

Of all painful disorders demanding a liberal outlay of opiates for relief, none so much so as neuralgia; and it is asserted by one prominent writer on the subject of stimulants and narcotics, that the principal cause of the wide-spread prevalence of the opium habit in this country is the increasing frequency of that disease, and the consequent freedom, amounting at times to recklessness, with which the anodyne properties of this drug are invoked for the mitigation of pain.

Now, it is well known that, in almost the entirety of cases of this neurosis, the exhibition of an opiate is but palliative, scotching, not killing, and exerts a curative effect only so far as, by lessening the susceptibility of the nerve affected, it affords it a chance to rest and an opportunity of regaining its lost tone; a loss every bout of pain increases, and the recovering of which is an absolute essential in the successful management of this hydra-headed disorder.

Again, in the light of recent researches and therapeutical advancement, it is safe to say that the greater proportion of neuralgic cases, other than those beginning somewhat late in life, admit of radical relief if a proper plan of medication be adopted; and of these we hazard little in opining, that a decided majority could be conducted to a successful termination without any such lavish expenditure of opium or its salts, as would expose the patient to the risk of confirmed intoxication.

On this point much has been given the profession of late years, and of those to whom we are thus indebted, none take higher rank than the lamented Anstie, whose classical work on this disease will long remain as a monument to his genius and self-sacrificing devotion.

Of course, it must be admitted there are many instances of incurably painful disease—cancer, locomotor ataxia and the like—where opiates in some form are imperatively demanded; but as in advanced stages of these disorders the fatal ending is inevitable, the same care is not requisite as in those painful but curable cases where, 'twixt two evils, we should choose the lesser,

which, while it might necessitate an increase of patience under suffering, for a time, would not incur the danger of which we have made mention.

In our opinion there is in many, perhaps the majority, of those individuals likely to become opium inebriates, a constitutional condition so in harmony with the snaringly seductive properties of this drug, that its administration in any form for more than a very limited period exposes them to the risk we have mentioned, being a soil in which the sowing of such seed is extremely liable to eventuate in a most bitter fruition. It is not ours to determine the precise nature of this condition, but we strongly suspect it to be largely akin to that peculiar diathesis so strikingly manifested in most cases of genuine neuralgia, the main element of which is a well-marked *hereditary* tendency towards a debilitated state of the nervous system, either special or general. So thoroughly do we thus regard it that, given a case of painful disease, in which the demand for opiates was urgent, and where it might be found essential to continue them for quite a prolonged time, we should deem the probability of forming a habit of opium inebriety in quite direct proportion to whether, on careful genealogical examination, were or were not found well-marked indications of the afore-mentioned diathesis. We do not wish, however, to be understood as saying that where these are wanting the risk is *nil*; nor, on the other hand, that in every instance where they are well manifested the patient is in danger, for we believe there are cases where the system is so intolerant of opium in any form that it is well-nigh impossible to establish a condition of confirmed inebriation.

While insisting upon the fact that physicians' prescriptions are largely responsible for the inception of opium addiction, it must not be overlooked, indeed it cannot be denied, that a most important auxiliary factor in establishing this vicious practice is to be found in the comparative facility with which, the appetite once created, its unhappy victims find means for its perpetuation and still further enslavement at the hands of the dispensing apothecary. As pharmaceutical rules and regulations are at present, this can be accomplished almost without hindrance, and on the easy morality involved in the principle, "If I don't, some one else will," a mode of moralizing which, as has been well observed, is an ugly commentary on the tendencies of the day, conscience can easily be lulled to slumber, and a fresh supply of fuel furnished the flame raging so remorselessly within.

Much has been done of late in elevating the standard of pharmacistical requirements, but more remains to be done. Legislative enactment, prohibiting the refilling an opiate prescription, or the dispensing of opium in any form, unless accompanied by a positive order from the attending physician, would, we are confident, accomplish an immense amount of good in protecting those who otherwise might become the pitiable possessors of a craving so horrible as to be well-nigh irresistible.

That the danger on which we have descanted is far fetched and improbable, we cannot admit. We believe it to be a *fact* staring the profession squarely in the face, and the sooner it rouses to a rightful realization thereof, the better will it be in reducing the ranks of a class of unfortunates deserving our deepest commiseration.

That the vice of opium inebriety would, to a certain extent, prevail despite an observance of the precautions alluded to, we do not doubt; but we unhesitatingly think it would be shorn, in large measure, of the strength it at present possesses, and its now rapidly augmenting proportions be thoroughly checked, and suffer a speedy decline.

In carrying out the reform we have indicated, it should be the aim of every practitioner, when called upon to prescribe this most valuable medicine, to see to it that he exercise a discriminating care in so doing, by careful inquiry as to the neurotic status of his patient from the stand-point of hereditary tendency, and if necessity demands a somewhat prolonged administration, to watch most warily and guard against most strenuously the earliest indications of an appetite that, thoroughly established, will scarcely be denied, and which entails upon its unhappy possessor a darkness so dense, a horror so indescribable, that death, at times, seems preferable.

COMMUNICABILITY OF DIPHTHERIA.

By P. B. PUMYEA, M.D.,

IMLAYSTOWN, N. J.

Is diphtheria contagious, is a question now often asked the physician, and his reply is one of serious importance.

Were it not for the diversity of opinion among physicians as to the communicability of this extremely fatal disease, a statement of the following facts would be unnecessary. The history of the origin and progress of diphtheria, now in my practice, shows its contagious character, and how it *may* be propagated and restricted (in so far as a few cases can).

Charles D., and Mary K., cousins, were both servants in the same family. Mary K. was taken sick with sore throat, and went home. Although complaining a good deal, no physician was called until her only brother was taken sick with sore throat, and was hardly able to swallow. An inspection of his throat at once revealed the nature of his disease, and his subsequent death showed its malignancy. As the neighbors were very much alarmed, no one came near the house, except an uncle, who volunteered his services. He caught the disease and communicated it to his family. Three of his six children died.

On December 5th I was called to see Charles D., the cousin before mentioned, and ascertained that he had diphtheria. As he was not confined to his bed, and his employer did not wish to endanger his own family, he immediately took him home. Less than two weeks subsequently the disease appeared in that family. There were five boys and five girls, and as far as possible the girls were kept away from the boys. Not until all the boys had had the disease and recovered from it did any of the girls take it. They now have it, and one, the youngest, has died. The oldest girl did not live at home, but when she ascertained that her brothers were sick, she came home to visit them and thus caught the disease.

These three families live within a radius of half a mile, and there is not nor has not been another case of diphtheria within a radius of five miles.

Was not the disease in these cases communicated by contagion and its propagation restricted by isolation?

We may not always be able to trace the origin and growth of this insidious disease. Sporadic cases undoubtedly occur, as in scarlatina. Sometimes the atmosphere seems to be so loaded with the contagious miasm as to produce an epidemic. But our inability to trace it or its epidemic character does not disprove its contagiousness, no more than it would that of pertussis or variola.

Prof. Smith, in his work on "Diseases of Children,"

says that the "communicability of this disease is as securely established as almost any doctrine in pathology."

It is much to be regretted that there is not *entire* unanimity of opinion among physicians in regard to the contagious nature of this disease, and that the people are not taught to shun it as they would small-pox.

When both the profession and the people acknowledge and appreciate the communicability of diphtheria, *then* it may be more restricted, and our children better protected from this insatiable monster.

Progress of Medical Science.

Fatty Embolism as a Cause of Sudden Death after Injuries of the Bones.—Prof. V. Czerny, of Freiburg, discusses this subject mainly in its clinical aspects, taking the reports of two cases as a text, and gives abundant references to current literature bearing on it. The first case was that of a healthy man of 24, who sustained a simple fracture of the right thigh in its upper third, the result of being buried by the falling of a sand-bank. This was on Nov. 16. The surgeon who was called to him found that he suffered little pain at the seat of the fracture, but could not lie down without difficulty, especially on the back, and could not breathe easily. On the 18th, the swelling having subsided, a pasteboard splint was applied, the patient at the time finding it very difficult to maintain a half-sitting posture. On the night of the 20th great dyspnœa and depression suddenly manifested themselves, without inflammation, and he died on the 22d. The authorities subsequently had the body disinterred and examined. The fragments of bone were in proper position, but both lungs were full of venous blood, and the membranes, substance, and blood-vessels of the brain also similarly filled. It appears that E. Wagner in 1865 stated his opinion that a sudden fatty embolism was capable of inducing hyperæmia of the lungs, œdema, and death; and in 1866 F. Busch established that the medulla of the bones when crushed was taken up by the veins and lymphatics, and caused emboli in the lungs, and death. Still these views do not appear to have been very generally recognized, although cases of fatty embolism causing sudden death have been occasionally reported. Czerny's second case is as follows: J. S., aged 32, a strong and healthy mason, sustained a simple fracture of the right thigh just below the middle, as a consequence of a fall from a scaffold. He also had a flesh wound on the chin, which was sewed up and dressed antiseptically. He was taken at once to the clinique, where dressings and applications of ice were made. He complained very little of pain, although quite conscious. This on Nov. 14, 1874. On the following day Prof. C., in a clinical lecture on the case, mentioned that, although free from fever on the previous day, his temperature that morning was nearly 103° F., and he gave a guarded prognosis. In the evening the temperature was almost a degree higher. Although at night he had no pain, he was restless, and had at intervals of three hours two doses of about $\frac{1}{3}$ gr. each of morphine. Some hours after midnight he was found comatose, with deep and frequent respiration, accompanied by coarse râles. The chest was resonant on percussion. Pulse 100, full and strong. He was bled from the arm, but obtained no relief, and died at half-past seven, thirty-eight hours after the injury. At the autopsy both lungs contained air and fluid. The left side of the heart was contracted, and there were coagula in both sides. The vessels of the pia mater and of the brain were distended with blood, and in both of these were numerous small ecchymoses. There were extensive extravasations of blood at and about the seat of fracture, but the femoral vein and artery were not wounded. The microscope revealed throughout the lungs a firm injection of all the smaller arteries and the capillaries, with clear fluid fat. Likewise in the brain, corresponding to the small ecchymoses, were branching fatty emboli in the vessels. Fat was also in the vessels of the kidneys and liver. The fatty embolism of the lungs was considered a sufficient cause of death. Prof. C. has given *in extenso* the reasons which led him to express the opinion, as he did before the autopsy, that fatty embolism would be found. He quotes the statement from Busch that fatty embolism begins in the first few hours after the injury. The difficulty of respiration would point to this condition. Possibly the slight sensitiveness to pain may also be symptomatic of it. He made a series of experiments on animals to clear up some points in his mind, but the results do not appear to have been very positive. Shock cannot be held to explain a death after injury, when an interval of several hours of good condition has intervened between the injury and death. He concludes that fatty embolism is of essential significance only after injuries of the bones, and perhaps osteo-myelitis. We may suspect this condition when after such injuries a rapid failure sets in, with interference with the circulation in the lungs; and secondarily in the general capillary circulation, without other cause, and very shortly after the injury is received. It should be accepted as a sufficient cause for death, however, only when the autopsy reveals a degree of it so extensive, or in such important organs, as materially to interfere with their functions.—*Berl. klin. Wochenschrift*, *Nov.* 1 and 8, 1875.

Oxide of Silver in Locomotor Ataxia.—Dr. Chas. Carter has treated two cases with this drug. In one case of seven years' standing, one half-grain doses three times daily were given. The quantity was gradually increased for seventeen weeks, until ten grains three times a day for one week were administered. It was then found necessary to suspend the medicine on account of a severe attack of diarrhœa, which subsided without further treatment. During these seventeen weeks the neuralgic attacks, which before were so frequent and painful, had only occurred three times, and then very slightly. Reflex action, and the power to flex and extend the feet, were now well marked. Before treatment the patient was unable to walk the streets at night, or stand with his eyes closed. He now could walk at night, but was still unable to stand with closed eyes. In the second case, of three and one-half years' standing, there was chronic diarrhœa as a complication. After getting the diarrhœa under control, the oxide of silver was given in half-grain doses, which proved quite sufficient to relieve the neuralgic attacks. The treatment extended over a period of three months, and with results as satisfactory as in the first case. These cases of Dr. Carter's would seem to show that the oxide of silver controls the neuralgic disorder in advanced cases, and even arrests the further progress of the disease.—*The Medical and Surgical Reporter*, December 18, 1875.

HOSPITAL CONSTRUCTION AND ORGANIZATION.*

II.

THE question next in importance to the adequate preparation of ground surface, is the material of which the buildings are to be composed, and their concretion and arrangement into structure. What is generally said by writers as to this matter, is too often but the expression of taste, or in utter disregard of the health-considerations involved. Some of our authors speak merely at a venture, without appreciating the significance for health involved, in choice of material.

Dr. Billings (p. 15) refers to "impervious walls," but expresses a great doubt (p. 28) whether it is feasible to attempt to make walls and ceilings impermeable. He speaks both of a hollow wall and of a space between plaster and wall, such as we have in ordinary furring and lathing, and suggests such construction of the space as will permit it, when needed, to be charged with chlorine or sulphurous gas for disinfection.

Dr. Folsom (p. 66) advises a brick construction of double wall, with closed air space and plastering directly on brick work, and so prepared as to be "hard, smooth, and *impermeable like stone*, so that they can be freely scrubbed; or if this is impracticable, very thin furring should be so attached as to be easily removed and replaced." A coat of paint occasionally is also suggested. J. (p. 112) gives an indiscriminate choice between brick, stone and iron, and suggests granite as the most durable. "The walls should be impermeable," and Parian cement or glazed tiles or slabs joined perfectly by a good cement should form the surface wall inside. The floor of the same should be covered with oil-cloth.

Our next author (p. 197) says that "north walls, even if wholly impermeable to air, become chilled," and so require much heat to keep rooms bounded by them warm. If stone be used (p. 199) it should not be so white as to be glaring, or so dark as to be gloomy. Whatever be the exterior, the inner walls and the lining of the outer should be of well burned brick well-laid with strong mortar. He also advocates an air space. Plastering should be applied directly to the walls, with hard plaster well polished as a finish. His remarks (p. 201) as to wet cleansing contrast strongly with those of Dr. Folsom (p. 66), and as to floors with those of Dr. Jones (p. 112).

S. recommends porous brick, hollow walls with air space, which may be fumigated, and plastering to be on lath, with a good hard finish surface. He speaks of porous walls as if they needed care as to cleansing, and of hollow walls as warmer and less liable to dampness. He also (p. 312) suggests that the air spaces may be made to communicate with the hot air chamber for warming. He suggests washing or gaseous disinfection of walls, and in a note of Angus Smith's draws attention to dry rubbing. A reference is made (p. 302) to the roofing of glass and iron of the Grand Central Depot, but preference is given to the common ceiling.

Mr. Niernsee (p. 331) constructs the orphan asylum of brick, with high-pitched and band coursed slated roofs, with all partitions of brick. He lays down as an axiom (p. 336), "that the most impervious material should be used for inside construction of hospitals," and quotes (p. 337) "high authority" for two-story structures, "provided the materials used are as *impermeable* as can be obtained. The outer wall (p. 338) is to be double and hollow, and the whole inside to be so coated and polished as to be impermeable." If this fails, Dutch tile or glazed earthenware are to be used, or the walls lined with one-quarter inch corrugated glass, both of which are declared "absolutely impermeable." The flooring, also, may be encaustic or glazed pottery tile.

The views thus expressed by some of our authors seem to be in the wrong direction, and to fail in comprehension of one of the chief designs of structure. A building for habitation is not intended, in any of its parts, for the entire exclusion of outside air. Its design is to protect from winds and storms, and to modify outside temperature to that extent which sedation or sickness or any changed condition of the in-dwellers may require. All this is perfectly consistent with the admission of air without perceptible currents through all parts of the structure itself. Indeed, without this we are more liable to that impurity of air which causes abnormal sensations of heat and cold. In the very building-walls we create sources of dampness which cause chilliness and disturbed temperature. The great problems of heating and ventilation are more involved in materials for structure and its seam-

* HOSPITAL PLANS. *Five Essays Relating to the Construction, Organization, and Management of Hospitals.* Contributed by their Authors for the Johns Hopkins Hospital, of Baltimore. New York: William Wood & Co. 1875. 8vo, pp. 353.

tific arrangement than in the discussion of special contrivances, important as these latter may be. It is not impermeability of walls that we want at all, but such permeability for air as prevents both dampness and draught. Long since the distinguished chemist Roscoe (in the *Chemical Transactions*, London), insisted on porosity of wall structure. The more recent investigations of Pettenkofer, Tarn, and others, no longer leave it a question that in the accurate study of structure throughout we are to seek to abate many of the demands now made for artificial *addenda*. Already the porosity of different material, of different specimens of the same general material, the best modes of combining mortar, cement, grouting, or other soft mixtures for interspaces is being tested. Richardson, in his recent "Model House," even objects to sea sand as unfit for walls because of the salt it contains. If material is too porous, it becomes the sponge for water instead of for air. If too compact, it retains dampness, and cannot be kept dry on account of the exclusion of air. We have before us an examination of bricks made by the chemist of the St. Louis Board of Health, in which bricks taken from different buildings varied from 1 to 15 ounces in the amount of water they would absorb. Different clays and different methods of mixing, pressing, and burning, give different results, independent of mere hardness. We have by actual experiment found large variation in this regard. In one case, by arranging bricks of different porosity in successive layers, we secured without air spaces a dry surface for plastering inside and a dry house.

The question of giving a smooth, unadherent surface to an inside wall, is quite different from the advocacy of air impermeability. In fact an air-tight surface acts as a condenser, and so secures a film of moisture which can do more than all else to catch and locate fomites. The experiments of Franklin and of Wells on the relations of different materials as to heat and moisture, apply directly to clothing, and just as directly to structural protection. A dress which is not too closely woven or pressed, is warmer than too close material, because the air in the interstices prevents moisture, and is a poor conductor of heat. In a building we want a smooth wall, with rightly modified porosity. Hollow walls do not accomplish this alike for all substances or for all localities. The spaces may become the dwelling-place of dead air. As generally arranged, they are crossed with girders for the anchoring of walls, and so are not continuous spaces. We commend to physicists the study whether continuous courses of bricks or material of varying porosity are not more likely to secure dryness, ventilation, and uniformity of wall temperature. If spaces are wanted for fires or ventilating, is it not better to have successive flues rather than one continuous space.

We know of no good reason for plastering directly on the structural wall, although far more feasible on the kind of inclosure we have indicated than on the other. Lath and plaster wall, when rubbed to a polished smoothness and perhaps painted with zinc, is permeable. The interspace made by furring and by the lath is favorable to ventilation and equalization of temperature, and the spruce lath are in no danger of impregnation. It is a question whether chimneys in the part facing rooms may not be made of soft or porous brick, so as to act with some ventilating power throughout their length. In an occupied ward the draft toward the chimney is quite assured, or if not can always be secured. Brick partitions between the rooms, or a row of brick inside plaster walls on lath, probably serve to aid equalization of air by their porosity. These are matters for exact experiment. We can only speak of the indications of science as illustrated in the general laws of air circulation, and in view of some definite experiments already made. These, thus far, plainly call upon us to forsake the "impermeability" idea, and point us to investigation as to the degree of porosity demanded, and the methods by which it is best secured.

The roof inclosure, too, needs large attention, just because it is a part of inclosure, and involves the same general principles as are concerned in the other "walls." Its different inclination to air, sunlight and storm, must be studied, but not to the exclusion of those principles which apply to the porosity of the sides. Should not the rafters be so boarded and finished as to admit of the interposition of such material on the under-side as will properly graduate the entrance of air and heat? The roof of the Kirkbride Asylum, Philadelphia, is "slate fastened on lath, and plastered with hair mortar on the upper and under edges, and on the points of the slate." The suggestion made by Niernsee (p. 332), as to the use of cement concreting on the flooring directly under the roof for fire-proofing is more important for damp-proofing. A mason, however, has told me, that since the quick cement is used so much in place of lime and sand mortar, buildings are damper. We have been saved from the evils of every roof-inclosure in part by the fact, that the attic has usually been an open space, but with our mansard and round ceiling, and ridge finish, we have reason to study it as we do side-inclosure.

For the admission too of air, sunlight and heat, this part of the building admits of large utilization, and both in itself and in its apertures is a structure study. We would thus direct attention to the whole matter of building material and inclosure, as one upon which the opinion of any doctor who walks a ward and prescribes for patients is little worth, unless as a physicist he has made special study as to the play of physical forces on and through dead matter, and the laws by which structure modifies outside conditions. We would relegate the subject not to surgeons or architects or engineers, except so far as they may be medical or sanitary physicists. Because we understand dis-

cases and their laws, it is unfair to expect that by the general results of our treatment of hospital cases, and our sense of smell and inhalation, we should be able to decide as to the adaptability of different geological formations for inclosure. It may be well to get our general views, and suggestions as to the direction of inquiry and as to those points where our sciences approximate, but the experts in that line must come from a school of technology, and not from a medical institute.

The suggestions of our authors as to these parts of the inclosure are for the most part very practical. We think with Niernsee (p. 338), that the boxes and sashes of the windows can be made of cast iron at a small advance over the cost of hard-wood frames, and have the advantage of being less absorbent and fire-proof. Dr. Billings (p. 26) would not have a window to each bed, but would have them in three parts with square top and glazed with plated glass. Dr. Folsom has (p. 79) between the beds on three sides of the wards windows three feet wide, three feet from the floor, and ten feet high, the rooms being fourteen feet high at the wall, and finished to twenty feet at the centre. He has ordinary sashes below, "and the upper two feet, above a transom, having a sash hung on hinges at the bottom," opening inward and provided with sides so that the entering air is directed upward. It is suggested that all sashes be doubly glazed with an air-space between for non-conduction of heat. Dr. Jones (p. 116) says, "the windows in the wards should be numerous, opposite each other, and should reach from the ceiling to the floor. Dr. Morris (p. 202) opposes this last, but advocates double glazed windows, and inside-shutters for shade. Outside awnings of canvass are also suggested for summer, and the window-seats or sills are to be of polished slate. Dr. Smith (p. 300) has eight feet of wall space to each bed with a window four feet wide, the windows, on opposite sides alternating, with double sash for warmth in winter, and as a means of ventilation without currents, and extending to the floor. Morris (p. 338) advocates the double-sash window, double hung, the sashes being eight to twelve inches apart, and prefers this to the transom window of Folsom. Thus by opening the upper outer and the lower inner sash ventilation is secured without draught. When shut an air space and heat regulator is afforded. In the orphan home (p. 332), the windows on the north are double glazed, and revolving self-coiling shutters outside, take the place of Venetian blinds. The plan of Folsom as to windows with transom above, strikes us most favorably. Instead of the hood openings, Oppert (Hospital Infirmaries and Dispensaries, London, 1867) has perforated zinc plates at the upper part of the upper sash outside, which therefore, do not furnish a place for the lodgment of dust or organic matter. When the ceilings are rounded to twenty feet, as in his one-story structure, the windows should extend up to the side-ceiling, as suggested by Jones, but not to the floor (Jones & Morris). Doubled-sashed and doubled glazed windows tend to equalize temperature, but we are all along afraid lest the attempt to exclude draughts be carried so far as to impede air circulation. The double-sash if properly managed, however, is very available for regulating egress and ingress of air. Windows do far more for us as ventilators when shut, than they get credit for, and the variation in material from the rest of the inclosure is serviceable. We are constantly to bear in mind that the climate of Baltimore is not that of New England or Old England either. We prefer windows not quite so wide as four feet, and notwithstanding the reasons given by S., believe they are best opposite each other with full room for beds between.

The same objection which is made to corners or mouldings will apply to pulleys and cords, and window fastenings, and also to door-furniture, and especially keyholes, so that these must be so made as not to harbor organic matter, and admit of easy cleansing. We cannot with Dr. Morris approve inside slatted shutters for shade, but much prefer the outside revolving, self-coiling blinds of Mr. Niernsee. Doors and their casings need to be of hard wood, thoroughly plain and oiled or painted. In many cases a part of these may be of glass, and a transom overhead is frequently needed for ventilation.

The inside woodwork should be of hard-grained and oiled wood, closely jointed. All mouldings should be avoided, but when there is necessary projection, as over doors (Dr. Folsom), the lintel should slope away from the wall so as to be easily cleansed of dust. The directions of Dr. Morris (pp. 200–201) are excellent as to the floors, etc. The glazed tiles and oil-cloth of J. will not do. There are reasons for impermeable floors arising from horizontal position, and from their being the natural receptacles of the organic matter afloat. Even these must be impermeable only on the polished surface, and not so smooth as to be slippery. Corrugated glass, as now being prepared, has some claims for consideration here.

All corners should be rounded, and cement used for base board, as suggested by Dr. Morris (p. 200). But this too must be so smooth and painted as to admit of easy cleansing. If there is danger of breakage from movement of beds and furniture wainscoting finished to the windows may be used, if very carefully jointed. All cornices are to be avoided, and the ceilings are better rounded, so as to avoid corners, and they thus, in some degree by shape, favor diffusion and exchange of air. It is difficult to dispense entirely with shelving in wards, but whatever is needed in addition to the window sills should be of polished slate or glass, supported by smooth metal brackets, with a small interspace between the shelf and the wall.

With our present varieties of oils, varnishes, and colorings it is easy to suit painting inside and out to taste and health. The rules which guide should be

just those which philosophy furnishes, and should be governed by exposure, sunshine, etc. We would not, for instance, paint a summer-house black for the same reason that we would not wear our blackest cotton clothing in the tropics. We have the authority of Miss Nightingale so often quoted by our authors that the best wall now extant is oil-paint. It is smooth and easily cleansed, without being impervious of air any more than a painted board is. Zinc paints are generally to be preferred to lead inside.

House pipes enter so much into structure as to demand our next consideration.

Reports of Societies.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, January 20, 1876.

DR. S. S. PURPLE, PRESIDENT, IN THE CHAIR.

ON THE CAUSES AND TREATMENT OF CASES OF UNUSUAL UTERINE HEMORRHAGE.

DR. H. T. HANKS read a paper upon the above subject, in which he confined himself to the consideration of those diseases most commonly attended with menorrhagia and metrorrhagia. After reviewing the well-known means for making a diagnosis, the doctor proceeded to notice the diseases in which hemorrhage from the uterus is more commonly a prominent symptom, and followed his remarks upon this part of the subject with a recital of illustrative cases. The more notable of these were the following:

Two cases of uterine fibroid, one sub-peritoneal, the other sub-mucus, which were treated by hypodermic injections of ergot with marked benefit. One case of endometritis terminating in retroversion, which was gradually relieved and cure finally effected by the use of the cotton tampon soaked in glycerine, following it the second or third day with an Albert Smith pessary. A case of granular erosion of the os and cervix was mentioned, which had been successfully treated by the local application of strong nitric acid, iodoform, and the use of the glycerized cotton. Objection was raised to the use of nitrate of silver in such cases, because of the liability to produce a condition which gives rise to sterility. A case of cancer was cited, in which hemorrhage became a dangerous symptom, and was controlled by the application of liq. ferri sesquichloride upon cotton twice a week.

The Doctor also made reference to several diseases in which menorrhagia is sometimes present, but does not form a prominent symptom, such as to demand the special interference of the physician. Among these were blood-poisoning, as from measles and scarlet fever, menorrhagia occurring with phthisis, pelvic cellulitis, and peritonitis, accompanied by slight metrorrhagia, etc., etc.

DR. PEASLEE, in commenting upon the subjects brought forward in the paper, mentioned two points in pathology which he regarded as very important. The first related to the development of retroflexion by endometritis. He was of the opinion that probably not one in five hundred cases of retroflexion of the uterus had an antecedent history of endometritis. Further, he was of the opinion that endometritis cannot produce displacement of the uterus, for the reason that the weight of the membrane, increased as much as it ever is when inflamed, is not sufficient to produce any effect whatever towards a displacement. If the two conditions are present at the same time, it is simply a coincidence. There may be present a hypertrophied condition of the endometrium, as a result of long-continued active congestion, and such a congestion may produce displacement, but not congestion simply of the endometrium. In order to produce retroflexion, if produced by increased weight of the organ, there must be an affection of something more than the endometrium, that is, of the parenchyma of the uterus. But we are now speaking of the effects of congestion and inflammation upon the endometrium.

The second point was with reference to the term granular erosion. There is no erosion whatever; and if there were an erosion, there is no granulation. It is simply a granular appearance, which has also been called ulceration. But there is no loss of substance from the part, except a mere desquamation of the epithelium. The granular appearance seen is due simply to hypertrophy of the normal papillæ of the part, which when normal are covered with epithelium which presents a smooth surface. When the papillæ become enlarged, the epithelium is lifted up, degenerates, and is swept away, leaving the papillæ bare. It is not erosion or granulation. As a rule, this condition is never found upon the cervix of a woman who has not been pregnant. It is characteristic of the woman who has been pregnant, and is difficult to cure unless thoroughly treated. The treatment the doctor recommended was to cut all these so-called granulations down level with the cutting curette, and then apply cotton, with or without glycerine, so that the raw surface shall not come in contact with opposing surfaces. The freshened surface heals in a short time, as a rule, unless another condition remains, namely, a basis of active congestion. If there is still remaining a surface in which the blood-vessels are distended, scarify that surface and remove the active congestion, and with it the cause of the growth and hypertrophy of the papillæ.

There is another class of cases, closely allied to those just mentioned, in which there is present a hypertrophy of the papillæ just within the os, and extending upwards one-eighth and perhaps one-fourth of an inch. This condition may be developed in the same manner as the other, but is almost invariably seen in the woman who has never been pregnant. The hypertrophy is sometimes so great, the mouth of the uterus is entirely closed by these growths. The method is the same as recommended in the other class of cases.

At this point the doctor spoke of scarification as the best possible means that can be employed to relieve uterine congestion. Leeches are used, but scarification is much more efficient, and can be readily performed in the cervix, and even the entire cavity of the uterus. It was maintained that the most certain method of relieving a patient of membranous dysmenorrhœa, is to so relieve the internal surface of the uterus of congestion by scarification that it cannot get this membranous growth.

The cotton and glycerine is an excellent application for the relief of local congestions, and he constantly resorts to it in anæmic persons; but its effects are small as compared with those obtained by scarification.

Dr. Peaslee then referred to carcinoma uteri, but to that class of cases only in which hemorrhage becomes an alarming symptom.

To arrest the hemorrhage the persulphate of iron is

a useful preparation, if a simple styptic is desired. His method of treatment, however, was to remove every portion of the fungous growth with a cutting curette, down to the scirrhous base below.

If the woman has already lost considerable blood, and is anæmic, it is best to resort to this procedure, for a fatal hemorrhage may attend any delay, and if the parts are well exposed and the fungus removed quickly, as a rule, severe hemorrhage does not attend the operation. If the scirrhous tissue below is cut through, a profuse hemorrhage will follow, but if only the fungous growth above the scirrhous base is swept away, not much hemorrhage will be produced. This operation will arrest the growth of these little fungous projections for a time, and if regularly repeated, perhaps every two or three weeks, it will check the progress of the disease, and the life of the patient may be prolonged for one year or more. An illustrative case was related, in which the patient's life was prolonged for a year, and when death did occur it was not from hemorrhage or septicæmia, but from a gradual failure of vital power.

(The remarks of Dr. Barker can be found on page 65.)

NEW YORK MEDICAL JOURNAL ASSOCIATION.

Stated Meeting, Jan. 7, 1876.

DR. F. P. FOSTER, VICE-PRESIDENT, IN THE CHAIR.

ALOPECIA AREATA.

DR. H. G. PIFFARD read a paper upon the above subject, in which he gave a brief history of the affection, embracing its clinical manifestations, its causation, and its treatment. The name has usually been applied to circumscribed spots of baldness occurring upon the scalp, but the beard may be affected in the same manner, and also every hairy spot upon the body. The hairs fall out by the roots and do not break off close to the scalp. In some instances the baldness is permanent, and upon the other hand, a new growth of hair is sometimes spontaneous. It does not occur in advanced life, and is unassociated with any special internal derangement. Some have claimed that it is a parasitic affection, others that it is non parasitic. The doctor referred to reports of cases where the observations were thought to point strongly to contagion as a means of its propagation, and also mentioned the possible relation existing between alopecia areata and cases grouped under the common term ring-worm. Five cases were reported, which were regarded as sufficiently suggestive to keep us alive to the possibility of a closer relationship than has hitherto been suspected. Dr. Piffard has been unable to find the spores described by those who claim that alopecia areata is a parasitic affection; but he brought forward the idea that there was possibly a localized fatty degeneration at the points of bulging seen along the shafts of the hairs. It is possible that what have been heretofore regarded as spores were no more nor less than particles of fat. The treatment recommended was epilation of the hairs at the margin of the affected spot, followed by blisters and by stimulating applications, such as ointment of turpeth mineral, as soon as the blistered surface has healed. It may be necessary to repeat the epilation and blisters. A cure is usually effected in from two to four months.

DR. KEYES remarked that he had never been able to find any spores in this affection, and looks for a return of the hair at any time within two years. If the spot remains bald for a longer time the hair is usually never restored. His treatment has consisted in the internal use of arsenic, iron, and phosphorus, the external use of stimulant applications, varying in strength according to the sensitiveness of the patient, and in some cases the induced current was thought to have exerted a beneficial influence.

DR. BULKLEY regarded the disease as non parasitic. He had used equal parts of tinct. of capsicum and glycerine as a local application, and with good success. Arsenic is usually employed internally. He regards it as a neurotic affection, but did not regard electricity as a specially serviceable agent in its treatment.

DR. STURGIS referred to a case in which the disease was apparently due to syphilis, and disappeared while the patient was taking anti-syphilitic remedies.

DR. BULKLEY referred to a similar case.

DR. KEYES referred to a case where the disease was present in a patient supposed to be syphilitic, but he was of the opinion that the patient did not have syphilis.

DR. R. W. TAYLOR remarked that he had not been able to associate the disease with syphilis. He had seen cases in patients as young as four and as old as fifty-two years of age. A change in the stimulant application used he regarded as being better than the use of one remedy continuously. Electricity combined with these may probably be of benefit.

DR. FOX regarded the affection as a neurosis.

DR. PIFFARD remarked that the conflicting opinions of different observers did not permit us to form any definite idea regarding the true nature of the disease. It is altogether probable that the fatty degeneration, to which he had referred as possibly being present in the hair, is a result and not a cause, and it is necessary, therefore, to cast about for an explanation of this change.

DR. F. P. FOSTER regarded it as quite possible for a ring-worm of the scalp to cause by reflex action, a true alopecia areata at a different part of the surface from that affected by the parasitic disease. In such case, the parasite would be found upon the hairs taken from the surface affected by the parasitic disease, and not upon the hairs taken from the surface affected by the alopecia areata. A parasitic *skin* disease would be more likely to produce a reflex disease affecting the skin than would a disease of some other structure of the body.

FEVER IN ROME.—*The Lancet* says that it appears from the returns of the Registrar-General that the annual death-rate in Rome, during the six weeks ending November 14th, was equal to thirty-seven per thousand. One hundred and eighty-three of the deaths during that period occurred among strangers and non-residents. The principal feature in the recent Roman returns has been a marked increase in the fatal cases of fever, which, during the six weeks under notice, have numbered no less than 220, equal to an annual death-rate of 7.5 per 1,000. During the last of these six weeks the deaths referred to fever in Rome were fifty two, a considerably higher number than in any previous week this year, and included twenty-nine described as "eruptive," ten as "febbre d'assorbimento," seven as intermittent, and six as typhoid. Considering the number of strangers who spend several weeks of the winter season in Rome, the sanitary condition of the place is not so good as could be desired.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, December 22, 1875.

DR. F. DELAFIELD, PRESIDENT, IN THE CHAIR.

(Continued from page 61.)

A CASE OF PERITYPHLITIS WITHOUT A DIAGNOSIS.

DR. DELAFIELD presented a portion of the colon, to which belonged a long history, yet a history of considerable interest, from the variety of diagnoses which were made, none of which were confirmed by the post-mortem.

The patient was a woman, thirty-nine years of age, who was admitted to Roosevelt Hospital Oct. 1, 1873. She said that she had been perfectly well until two months before that time, when she was suddenly seized with vomiting. This vomiting soon passed away, when she felt well until the next evening, when she vomited again. It again ceased in a few minutes, and recurred the next evening, lasting as before only a few minutes.

A few days after this she began to menstruate, it being her regular period. The discharge, instead of ceasing as usual, continued for three weeks, and during this time she lost a good deal of blood. During this time she had pain in the lower part of the abdomen in front, not constant nor severe, but it ceased with the termination of menstruation.

She continued to feel perfectly well until the first of September, when she was again seized with vomiting, and the vomiting continued during the day. At the same she had several slight chills during the day. This condition lasted for a week. The next week the vomiting ceased, she had no more chills, and was able to do her work during the morning, but in the afternoon there was nausea and lassitude. This condition continued up to five days before she entered the hospital. At that time she was seized with very great pain, tenderness, and swelling of the abdomen. She had been taking laxative medicines, and her bowels had moved several times. She would occasionally vomit during the day.

At the time of admission the vomiting had ceased, and the patient complained of severe pain and tenderness in the iliac and epigastric regions, and extending backwards. There was some redness of the skin, and a slight swelling in the right lumbar region. Her face was flushed, pulse 120, temperature 102° F., and respiration 36.

After her admission her general condition improved. Her vomiting was better, and her bowels were disposed to be loose. This looseness was controlled, and there was nothing special complained of but occasional vomiting, except that she had night-sweats.

On the 11th of October it was noted that the pain was more severe, and that a hard lump could be felt under the liver on right side. On deep pressure the pain seems to be very great, and yet when she lay upon the painful side of the abdomen the pain was relieved. On Oct. 18th she had signs of bronchitis—cough, expectoration, and night-sweats. Tenderness on pressure over right side still continues.

On Oct. 28th it was supposed that she was suffering from fecal impaction, and her bowels were pretty freely moved with purgatives, without any particular effect upon her condition. This was the first diagnosis.

Nov. 20th. There was a good deal of tenderness over the right kidney, and with the stethoscope there was heard a double murmur, which was limited to the right side of the spinal column, above the tenth rib. It was then supposed that there was an aneurism of the abdominal aorta, and this was the second diagnosis.

Nov. 22d. The same murmur was heard distinctly again.

Nov. 29. Her legs became swollen, particularly the left leg, and she had all the symptoms of thrombosis of the left femoral vein.

Dec. 2. She was examined by Dr. Draper, who suspected that there was abscess in the abdominal cavity, and that the abscess was probably due to the existence of caries of the spine, and this was the third diagnosis.

Dec. 8. It was noted that there was a soft tumor on the right side, at the level of the left edge of the kidney and external to it. The fluctuation was not very distinct. This swelling she said she noticed for the first time the day before (Dec. 7)

Dec. 9. Tumor has increased in size, and fluctuation is distinct. Urine normal.

Dec. 10. Was examined by Dr. Mason, who recognized the existence of pus in the lumbar region, and supposed it to be a post-renal abscess, the result of perinephritis. After this time the woman's general condition became improved.

Dec. 17. It was noted that the tumor, pressed upon from behind, produced gurgling in the abdomen, which could be felt in front, and finally the fluctuation and tumor disappeared. It was then supposed that the abscess had discharged its contents into the gut.

Dec. 27. She complained of pain and tenderness over the ileum, near the anterior superior spinous process, and here somewhat later fluctuation made its appearance, and an abscess opened.

Jan. 7, 1875. She was seen by Dr. Sands, who also supposed that she suffered from caries of the spine, that the abscess was the result of this, but he advised that the abscess should not be opened.

Feb. 21. She was seen by Dr. SCHAFFER in consultation, who likewise supposed the abscess secondary to caries of the vertebra, and advised aspiration. Dr. Weir also saw her at the same time, and concurred in the diagnosis and treatment proposed. The abscess was accordingly aspirated, and the swelling disappeared.

March 12. The tumor in the lumbar region returned, and opened spontaneously and discharged pus pretty freely. A little later a similar opening over the crest of the ileum, discharging pus. These openings were kept open and regularly washed out, when it was found that solutions injected into the opening by Poupart's ligament would flow freely from the one in the lumbar region.

At this time her fæces were examined, and pus having been found in them, it became evident that a communication had been made with the intestine.

Sept. 1. She was seen by Dr. Thomson, who made the diagnosis of perihepatitis resulting in abscess, the abscess communicating with the lung and the intestine. This was a further difference of opinion.

After this the patient progressed sometimes better and sometimes worse until within the last few months, when the abscess had entirely ceased discharging, and at the time of her death the external opening had almost entirely healed up. At the time of her death the symptoms which she complained of were those of phthisis, which had been developed within the last few months.

At the autopsy the brain was not examined. The upper lobes of both lungs presented the lesions of chronic disease, and in the apex of the right was a moderate-sized cavity. The heart was the subject of brown atrophy. The liver was somewhat increased in

size, and was in a condition of waxy infiltration. The kidneys were slightly increased in size, and had also waxy infiltration. In the peritoneal cavity was a large amount of clear serum, and the peritoneum lining the abdominal wall was somewhat thickened and roughened with little nodules, but there was no fibrine and no adhesions. The stomach was normal. The small intestines were in a condition of chronic catarrhal inflammation, with here and there a small superficial ulcer. The caput coli was firmly adherent behind to the posterior abdominal wall, and in this posterior portion of the gut was an opening capable of admitting the end of the little finger. This opening led directly into a very small cavity in the tissues beneath. This cavity was very small indeed, and was empty. Leading into this cavity were a number of narrow, flat sinuses, leading from these points beneath the caput coli to the old external openings. These sinuses were small and contracted, and contained no pus. All about them there was a considerable amount of dense cicatricial connective tissue, extending from the point of adhesion of the colon up to the lower end of the right kidney, and partly embracing it. That portion of the capsule of the right kidney was thickened, but the kidney itself presented no lesion but waxy degeneration.

At the time of death, then, the patient had entirely recovered from the original disease. The cavities had closed, as was virtually the case with the hole in the intestine. The caput coli, by the way, showed no other lesion save the perforation. The case seemed to have been one of perityphlitis, the abscess forming behind the caput coli. Whether originating in an inflammation and perforation of the caput coli, or originating as a phlegmonous inflammation of the connective tissue beneath the caput coli, neither the history nor the autopsy seemed to show. It seemed curious that the patient, after having been under observation so long, and having been seen by so many, a correct diagnosis was not made. Dr. Delafield made no diagnosis at all, and was beyond criticism.

Dr. Post exhibited two recurrent tumors which he had removed from the lower part of the right arm of a young man, aged 30 years. They were recurrent growths, making their appearance about two years after the first operation. They were situated near the lower extremity of the arm; one on the outer side, about a hand's breadth above the elbow; the other posteriorly, and a little below that level. They involved the muscular tissues of the limb, but the skin was movable over them and there were no glandular enlargements. The muscles involved in the growths were the triceps, the outer part of the brachialis anticus, and a portion of the supinator longus. All of the tissues of these muscles involved in the disease were removed with it. The operation was performed in this manner with a view of saving the limb, in lieu of an amputation, which was at first proposed.

The second specimen presented by Dr. Post was a tubular sequestrum, removed by operation from the popliteal region of the femur of a girl, seven years of age, who had suffered from osteo-myelitis of that part. The specimen was presented as a rare one of its kind.

The Society then went into executive session.

Religious Excitement.—The number of the *Medical and Surgical Journal* (Philadelphia) for January 22d contains a very readable and excellently written editorial on the "Physiological Aspects of Religious Excitement."

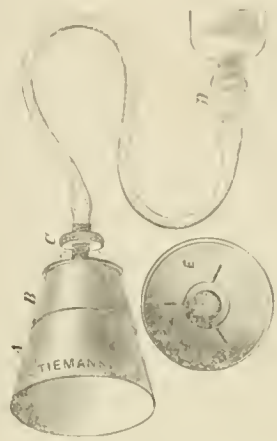
New Instruments.

A NEW APPARATUS FOR ETHER.

By W. CHEATHAM, M.D.,

NEW YORK.

I wish to call the attention of the profession to a new apparatus I have had made by Messrs. Stohlmann, Pfarre & Co., of 107 E. 28th street, New York, for the administration of ether. It operates by Lente's method of replenishing the evaporating surface without removing it from the face.



A patient cannot be anæsthetized as quickly with it as with a common cone, but with much less ether. It economizes by not having to remove it from the face to replenish it, and by this you avoid the disagreeable effect of having the ether that would otherwise escape permeating every part of the house in which it is used. Its convenience of application is also quite obvious. The ease with which the face-piece (being paper) can be removed immediately after use and thrown away is, I think, a strong recommendation in its favor.

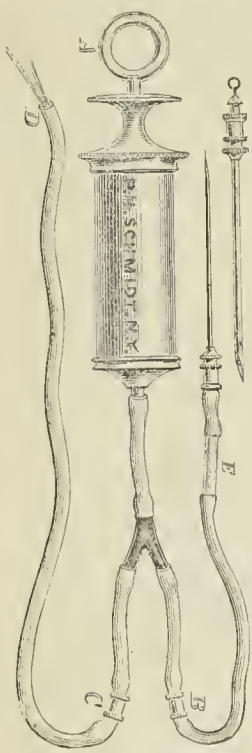
The apparatus consists of a tin cup (A), holding in the inside a sponge as an evaporating surface, and connected from the top by rubber tubing with the bottle that contains the anæsthetic. This tube has attached to its distal end a cap (D) that will fit over the neck of almost any bottle, doing away with Lente's graduated bottle.

Make a cone of paper, cut the top off, so when tin cup (A) is slipped inside the top of the cup will protrude a line or two from top of cone.

Place tin cup (B) over both cup and cone, screw it down tightly by means of nut (C), and you have the cone held tightly. Attach tube to top of cup, and the apparatus is complete. The smaller the cone the quicker you can get the patient under the influence of the anæsthetic. I would suggest after the cone is in position the bottom should be trimmed, leaving a part of it—we shall call it the back part—that is intended to go over the chin, three inches longer than the cup, and sloping forwards and upwards, leaving the front part, intended to go over the nose, about an inch longer than cup. E gives an inside view of cup (A).

DR. F. N. OTIS'S SIMPLIFIED ASPIRATOR.

The accompanying engraving represents a simple instrument, the original of which was extemporized from materials within the easy reach of every surgeon, and so combined as to form an *Aspirator*, complete and efficient for all ordinary purposes.



The "Simplified Aspirator" consists of an ordinary well-fitted syringe (A) of any convenient size, joined to which, by an inch of rubber tubing, is a short hard-rubber, metal, or glass bifurcating tube. To each arm of this tube is attached another bit of rubber tubing, which terminates in a hard rubber valve, such as is used in the construction of the Davidson syringe. These valves are arranged to work in reverse directions. On retraction of the piston of the syringe, the valve at B (connected by tubing with the aspirating needle) opens and permits access through the needle to the barrel of the syringe. The piston being driven back the valve at B closes, while that at C opens and empties the syringe through the connecting discharge pipe. Near the base of the needle a short glass tube is inserted in order to afford early information of the character of the fluid in process of evacuation. "The Simplified Aspirator" was the result of a necessity for an instrument sufficiently small to fit in my "retention case," and a one-ounce hard-rubber syringe was found to be sufficiently large for easy aspiration of the bladder. In an emergency it might be used for transfusion, simply by adapting a small canula to the discharge pipe. This instrument has been duplicated by Mr. Schmidt, the surgical-instrument maker, corner Thirty-fourth street and Broadway, and is put up in a case with two sizes of aspiration needles, for nearly one-third the price of an ordinary aspirator of the cheapest description.

F. N. Otis, M.D.

108 West 34th Street.

CHANGES IN THE PUBLIC SERVICE.

ARMY.

Official List of Changes of Stations and Duties of Officers of the Medical Department United States Army, from Jan. 16th to Jan. 22d, 1876.

Taylor, M. E., Assistant Surgeon.—Assigned to duty at the Post of McComb City, Miss. S. O. 9, Dept. of the Gulf, Jan. 14, 1876.

Epileptic and Paralytic Hospital.—Dr. L. D. Bulkley has been appointed by the Commissioners of Public Charities and Correction Visiting Physician to the Epileptic and Paralytic Hospital, Blackwell's Island, *vice* Dr. E. C. Seguin, resigned.

Medical Items and News.

New York Orthopedic Dispensary.—At the annual meeting of the Board of Trustees Jan. 10th, the following Medical Board was elected for the ensuing year:—

Consulting Surgeons: Drs. F. H. Hamilton, T. M. Markoe, Henry B. Sands, Stephen Smith, and William H. Van Buren. *Consulting Physicians:* Drs. William H. Draper, A. Jacobi, and John T. Metcalfe. *Consulting Orthopædic Surgeon:* Dr. C. Fayette Taylor. *Consulting Oculist:* Dr. C. R. Agnew. *Consultant on Nervous Diseases:* Dr. E. C. Seguin.

Attending Surgeons: Drs. John G. Curtis, George A. Peters, Thomas T. Sabine, and Newton M. Shaffer.

Orthopædic Surgeon: Dr. Newton M. Shaffer.

Assistant Surgeons: Drs. S. A. Foster, George B. Packard, and A. B. Judson.

The Canadian Journal of Medical Science is a new monthly quarto of thirty-two pages, in the style of the *Canada Lancet* and *Canadian Medical Record*. Uzziel Ogden, M.D., Lecturer on Midwifery and Diseases of Women and Children, in the Toronto School of Medicine, is the Editor; and R. Zimmerman, M.B., L.R.C.P. Lond., Demonstrator of Microscopical Anatomy in the same school, is the Corresponding Editor. The volume commences with the year, and the subscription price is three dollars.

Kings County Medical Society.—At the last annual meeting the following gentlemen were elected for the ensuing year:—Alexander Hutchins, M.D., President; J. S. Prout, M.D., Vice-President; R. M. Wyckoff, M.D., Secretary; J. D. Rushmore, M.D., Assistant Secretary; G. G. Hopkins, M.D., Treasurer; W. W. Reese, M.D., Librarian; Doctors Baker, Buell, Burge, Jewett, and Matthewson, Censors.

Medical Society of State of New York.—No legislative action having been taken in regard to changing the time of meeting of the Society, it is proposed that a sufficient number of members in Albany and its vicinity shall meet at the regular time, organize, and then, without transacting any business, adjourn until June next.

Medical Legislation.—The *Canada Medical Record* is much exercised concerning a prospective "Act concerning the Medical Profession of the Province of Quebec." Like all other bills of its kind, it is said to be exceedingly impracticable, and "utterly impossible of accomplishment;"—the same old story.

Presbyterian Hospital.—Drs. C. K. Briddon, John H. Hinton, and L. A. Stimson have been appointed attending surgeons.

Scarlet Fever; Two Attacks in One Patient within Two Months.—A correspondent of the London *Lancet*, of January 8th, reports a case of the above.

The Louisville Medical News is a very sprightly readable journal, but Dr. Cowling, its editor, is not yet sound on the patent-medicine question. We believe he is yet open to conviction.

Weekly Bulletin of the Meetings of Medical Societies.

Tuesday, Feb. 1.—New York Obstetrical Society; New York Dermatological Society.

Thursday, Feb. 3.—New York Academy of Medicine, 16 W. 31st.

Friday, Feb. 4.—N. Y. Medical Journal Association

Original Communication.

OSTEO-ANEURISM OF THE INFERIOR MAXILLA.

LIGATURE OF THE LEFT EXTERNAL CAROTID AND RIGHT COMMON CAROTID ARTERIES.

(Being a report upon specimens presented at the meeting of the New York Pathological Society, January 12, 1876.)

By EUGENE PEUGNET, M.D.,

FORDHAM HEIGHTS, NEW YORK.

CAROLINE M., 13 years and 10 months of age, was of healthy parents and of a naturally good and robust temperament. At about the age of 12 years her second inferior molar on left side made its appearance, and since that time she complained of more or less pain in the vicinity of that tooth. The left cheek began to swell at about the same time. On the mornings of the 31st of May, 1st, 2d, and 3d of June, 1874, her mother observed that the upper portion of her night-dress was considerably blood-stained. On the third of June, at about three in the afternoon, whilst in the act of washing her face, was suddenly taken with an alarming hemorrhage from the mouth, which only ceased with the occurrence of syncope. The hemorrhage recurred twice in the succeeding 36 hours. This was pronounced vicarious menstruation, as the patient had never had her menses since their first appearance in September, 1874, and the attending physician only prescribed lemonade as a drink.

On the 9th day of June the patient was removed from Williamsburg to her aunt's residence at Tremont, was then placed on a course of quinine and iron, with a generous diet. Although she recuperated rapidly, her left cheek did not diminish in size, but appeared to gradually increase, and the superficial veins became more prominent. Now and then she would complain of a pulsating pain extending from the chin along the ramus of the maxilla up to the left temporal region, which was controlled by sulphate of morphine in doses of ¼ of a grain. On the 3d day of July, early in the morning, before rising, was suddenly taken with an arterial hemorrhage from the mouth, arising from the vicinity of second inferior molar tooth of left side, which, after the loss of over two pints of blood, was arrested by the application of a compress of lint saturated with the perchloride of iron over left molar tooth. On the 4th and 5th the hemorrhage recurred twice, in each instance caused by the removal of the styptic compress.

On the 5th of July Dr. J. W. Hupfeld requested me to see her. I then found her remarkably exsanguine—with a pulse of 120, temperature about normal—complaining of a throbbing pain from the mental symphysis up to the left temporal region, an aneurismal thrill and bruit extending from the left supra-clavicular region, along the course of the carotid and temporal arteries, also of the facial and left mental. The superficial veins markedly developed. Owing to the instantaneous recurrence of the hemorrhage at the slightest attempt to open the mouth sufficiently, it was impossible to make a thorough examination within it. From the cursory examination thus made I pronounced it a cirsoid aneurism, and therefore advised ligation of the common carotid. In the meantime placed a compress over left facial and mental arteries, which controlled the throbbing pain, and gave the patient rest. Dr. Erskine Mason saw her on the 12th of July, confirmed the diagnosis, and advised ligation of the common carotid.

On the 16th of July, with the assistance of Dr. Henry B. Sands, and in the presence of Drs. J. C. Peters, Bathgate, Naudain, A. M. Campbell, Goodwillie and Hupfeld, I proceeded to ligate the left external carotid. It had been my intention to ligate the common carotid, especially as I had occasion to tie it on a previous occasion for secondary hemorrhage from the internal maxillary;* but the advice of Dr. Sands, as well as the cogent argument of Dr. Landon R. Langworth, in his able thesis on the ligature of the external carotid artery,† led me to alter my purpose and to ligate the latter artery. I made the usual incision for the ligature of the common carotid, along the anterior margin of the sterno-cleido-mastoid muscle, downwards two inches and a half. In the superficial fascia an enlarged facial vein was isolated, ligated and divided, the incision through the platysma myodes and deep fascia brought the sheath of the vessels and descendens noni clearly into view. I then opened the sheath and exposed the internal carotid, which was at first thought to be the external, as its compression arrested the pulsation in the facial and temporal, but in isolating it the error was discovered; the bifurcation was then sought for, but as it was evidently concealed by the bifurcation of the abnormally large facial vein and internal jugular, I passed a silk thread around the latter, with which Dr. Sands drew it cautiously to one side, thus exposing the arterial bifurcation. I then isolated the external carotid, which laid almost beneath the internal, thus accounting for the arrest of pulsation in the branches of the former, when the latter was compressed, and ligated it about 5 lines above the bifurcation. No other vessels were ligated, and the wound was brought together by 5 sutures. The operation, including the administration of ether, occupied 60 minutes.

10 P.M., P. 90; patient comfortable, no pain; left molar tooth loose; 11.30 P.M., P. 100.

July 17th, 7 A.M., P. 100; 6 P.M., P. 102. 18th, 7 A.M., P. 90, as the wound had united by first intention, I removed three of the sutures; 6 P.M., P. 100, patient wiped some blood, mixed with pus, from her mouth. 21st, 7 A.M., P. 112, spat considerable blood, and complained for the *first time* since the operation of pain in molar tooth; both were relieved by washing the mouth with ice water; 6 P.M., P. 100. 22d, 7 A.M., P. 98; 6 P.M., P. 100; 10 P.M., patient awakens, spits out some dark-looking clotted blood, and complains of intense pain in left tooth and cheek; ice water in mouth relieved her at once. 23d, 7 A.M., P. 90, slight hemorrhage from mouth; 6 P.M., P. 98. 24th, 7 A.M., P. 102; 12.30 P.M., a sudden arterial hemorrhage from wound in neck, which, after the loss of twelve or fourteen ounces of blood, was finally arrested by Dr. A. M. Campbell, who compressed the common carotid; at 3 P.M. I found the patient anxious but comfortable, P. 120; the common and internal carotids of left side pulsating with considerable force. 3.20 P.M., P. 126, administered tinct. veratrum viride gtt. v., and tinct. digitalis gtt. x.; 6.30 P.M., P. 98; 7.08 P.M., P. 100, administered tinct. v. v. gtt. v., tinct. d. gtt. x.; 9.25 P.M., P. 78, sleeping quietly; 10.25 P.M., P. 78; 10.35, P. 102, awakens; 10.40

* On the 21st of July, 1861, at the battle of Bull Run a private of Company F, 71st Regiment N. Y. S. M., received a gun-shot wound of the face, the missile entering the antrum on left side. On the 24th a severe hemorrhage from wound, again on the 25th and 27th, which could only be checked by compression of the common carotid on left side. On the latter date, with the assistance of Drs. G. S. Winston and C. Degraw, I ligated the left common carotid. 18 hours after the patient was removed from Sudley Church to Manassas, where Dr. Chopin kept him under observation for two days, then sent him to Richmond, there he sank into a typhoid condition, and died on the 11th day, at least so I was informed by Dr. White, of the 1st Rhode Island Vols.

† Dr. Brown Sequard's "Arch. of Scient. and Pract. Medicine," No. 5, 1873.

P.M., a sudden flow of blood from wound in neck, which I immediately arrested by compressing the common carotid, then applied a graduated rubber compress over carotid in supra-clavicular region; 10.55 P.M., P. 114, administered morphiæ sulph. gr. ¼, tinct. v. v. gtt. v., tinct. d. gtt. x.; 11.20 P.M., P. 108; 11.50 P.M., P. 86; 12 M., P. 82.

July 25th, 12.30 A.M., P. 94, administered tinct. v. v. gtt. v., tinct. d. gtt. x.; 1.20 A.M., P. 89; 4.10 A.M., P. 92, administered tinct. v. v. gtt. v., tinct. d. gtt. x.; 5.35 A.M., P. 95; 7.15 A.M., P. 66, sleeping quietly; 8 A.M., P. 66; 9 A.M., P. 72; 9.46 A.M., P. 82, administered tinct. v. v., tinct. d., āā gtt. v.; 11.25 A.M., P. 93, administered tinct. v. v., tinct. d., āā gtt. v.; 1.30 P.M., P. 80; 2.20 P.M., P. 77; 4 P.M., P. 120, not having urinated in twenty hours, twelve ounces of urine were drawn off with catheter; 4.10 P.M., P. 106, slight arterial hemorrhage from mouth, also sanguineo-purulent discharge from seat of ligature; administered tinct. v. v., tinct. d., āā gtt. v.; 5 P.M., P. 100; 6 P.M., P. 90, T. 102°; 7.12 P.M., P. 88, administered tinct. v. v., tinct. d., āā gtt. vj.; 10.48 P.M., P. 88, slight hemorrhage from wound in neck, immediately controlled by pressure on compress; 11.33 P.M., P. 93, owing to compression of carotid complains of considerable pain; very restless, administered morph. sulph. gr. ¼.

July 26th, 1.35 A.M., P. 78, administered tinct. v. v., tinct. d., āā gtt. vj.; 4.25 A.M., P. 72, sleeping quietly; 5.36 A.M., P. 72, T. 99; 5.35 A.M., P. 80, administered tinct. v. v., tinct. d., āā gtt. vj.; 6.35 A.M., P. 67; 7.55 A.M., P. 65, nausea and slight vomiting of viscid mucus; 8.50 A.M., P. 60, nausea and vomiting; 9.45 A.M., P. 60; 10.35 A.M., P. 64; 12.15 P.M., P. 74; 2.25 P.M., P. 96, administered tinct. v. v., tinct. d., āā gtt. vj.; 3.10 P.M., P. 88; 4.45 P.M., P. 78; 6 P.M., P. 72; 7 P.M., P. 80; 8.05 P.M., P. 78, complains of pain in tooth; 9 P.M., P. 100, pain continues; administered tinct. v. v., tinct. d., āā gtt. vj.; 10.40 P.M., P. 80, still complains of pain.

July 27th, 12.30 A.M., P. 80, pain in tooth; 1.15 A.M., P. 72, complains of pain in tooth, very restless; administered morph. sulph. gr. ¼; 3.10 A.M., P. 70, sleeping quietly; 6 A.M., P. 80, no pain; 6.45 A.M., P. 100, administered tinct. v. v., tinct. d., āā gtt. vj.; 7.45 A.M., P. 88; 8.55 A.M., P. 80; 9.20 A.M., P. 85; 10.20 A.M., P. 77; 12.30 P.M., P. 79; 3 P.M., P. 82; 4.50 P.M., P. 96, administered tinct. v. v., tinct. d., āā gtt. vj.; 5.55 P.M., P. 98; 7.10 P.M., P. 92, bowels move freely; 9 P.M., P. 90, marked pulsation in common and internal carotids, pain in tooth; administered tinct. ferri mur. gtt. x.; 9.55 P.M., P. 100; 11 P.M., P. 89.

July 28th, 12.10 A.M., P. 90, anxious and restless; administered morph. sulph. gr. ¼. 2 A.M., awakened suddenly with arterial hemorrhage from mouth, which *compression* of the *left common carotid failed to arrest*, but was instantaneously arrested by plug of lint, saturated with the persulphate of iron, over molar tooth; administered tinct. v. v., tinct. d., āā gtt. vj. 3 A.M., P. 111; 7.55 A.M., P. 112; 10.20 A.M., apprehending further hemorrhage, and the patient having been anæsthetized with ether by Dr. A. M. Campbell, I proceeded, with the assistance of Dr. H. B. Sands, and in the presence of Drs. Bathgate, Naudain, and Hupfeld, to ligate the right external carotid. The dangerous obstacles, as well as the unusually high bifurcation met with on left side, led me, with the concurrence of Dr. Sands, to modify the operation. Therefore adopting one somewhat similar to that of Malgaigne for ligation of the lingual, began my incision at a point half an inch above the angle of the inferior maxilla, opposite the lobe of the ear, carried it obliquely downwards two and a half inches, to a point midway between the sterno-cleido-mastoid and the vertical ridge of the hyoid bone, thus exposing the upper half of the superior carotid triangle, bounded behind by the anterior margin of the sterno-cleido-mastoid, anteriorly by the stylo-hyoid and posterior belly of the digastricus muscles, below by the greater cornu of the hyoid bone. This brought clearly into view the external carotid and superior thyroid arteries, the latter passing over the greater cornu of the hyoid bone, also the thyroid vein. Neither the jugular vein, internal carotid artery, nor any nerve, not even the lingual, was observed. I then passed a ligature around the external carotid about two lines below the thyroid, also one around the superior thyroid about three lines from its origin, both immediately below the digastricus and stylo-hyoid muscles, the insertion of the tendon of the latter muscle being distinctly observable. The wound was then brought together by four sutures and the plug removed from over molar tooth, and gtt. xxv. of aromatic spirits of ammonia administered; the whole operation, including anæsthesia, having occupied thirty minutes. 10.50 A.M., P. 98; 11.15 A.M., P. 80, administered sp. amm. arom. gtt. xxv.; 12.45 P.M., P. 110, T. 99½°, administered tinct. ferri mur. gtt. x.; 3.25 P.M., P. 105; 5.18 P.M., P. 118, administered tinct. v. v., tinct. d., āā gtt. vj.; 7 P.M., P. 102, administered tinct. ferri mur. gtt. x.; 11.15 P.M., P. 105, administered tinct. v. v., tinct. d., āā gtt. vj.

July 29th, 2.30 A.M., P. 100, administered tinct. ferri mur. gtt. x.; 4.05 A.M., P. 100, 6 A.M., P. 100; 8 A.M., P. 100, administered tinct. ferri mur. gtt. x.; 11.30 A.M., P. 108, administered tinct. v. v., tinct. d., āā gtt. vj.; 1 P.M., P. 108, administered tinct. ferri mur. gtt. x.; 5 P.M., P. 105, administered tinct. ferri mur. gtt. x.; 9 P.M., P. 99, administered tinct. ferri mur. gtt. x.; 10.15 P.M., P. 106; 12 M., P. 90, suddenly slight hemorrhage from mouth, which was spontaneously arrested; very nervous and anxious, administered morph. sulph. gr. ¼.

July 30th, 1 A.M., P. 90, administered tinct. ferri mur. gtt. x.; 5 A.M., P. 90, administered tinct. ferri mur. gtt. x.; 9 A.M., P. 104, slight sanguineo-purulent discharge from the mouth, administered tinct. ferri mur. gtt. x.; 9.30 A.M., P. 104, administered tinct. v. v., tinct. d. āā gtt. vj.; 11.45 A.M., P. 104; complains of intense pain in lower jaw, relieved by *compressing* the *left* common *carotid;* 12.05 P.M., P. 106; administered tinct. v. v., tinct. d., āā gtt. vj.; 1.25 P.M., P. 93; 3 P.M., as there had been an almost continuous oozing of blood from mouth since 9 A.M., I determined to make a further attempt to ascertain the exact seat of the hemorrhage, and to adopt such further measures as should be deemed advisable. The patient having accordingly been anæsthetized by Dr. A. M. Campbell, and the right common carotid compressed by Dr. Purroy, whilst I compressed the left one in order to *control* the *circulation* through the *internal carotids* and their *ophthalmic* branch, Dr. G. H. Goodwillie attempted to make an examination of the mouth. The doctor had barely opened the patient's mouth, and was about removing the plug of lint from over molar tooth, when the blood gushed *per saltum*, notwithstanding firm compression by the doctor over molar, which sank in the socket. Without exception it was the most appalling sight it has been my misfortune to meet with. The patient sank rapidly, and expired at 5 P.M.

Autopsy, twenty-three hours after death, made by Dr. A. M. Campbell: Rigor mortis well marked; body

well nourished. External incision on left side of neck, two and a half inches in length, united, excepting at two points; the ligature *in situ*. Incision on right side of neck, two and a half inches in length, united, excepting at points of egress of the ligatures around carotid and thyroid arteries. On opening the thoracic cavity, the lungs were found to be pale and exsanguine, with but slight hypostatic congestion, the heart empty and normal. I then threw an injection of melted wax, colored with cochineal, into the innominata artery, on the completion of which Dr. Campbell proceeded with the autopsy. Scalp bloodless, serous effusion beneath meninges, brain otherwise normal. The vertebral arteries and circle of Willis injected with wax, the left internal carotid also; the *right internal carotid* at *first supposed* to be *empty*, was *wanting*. The two vertebral and basilar quite large. The *left* posterior communicating *wanting*. The two

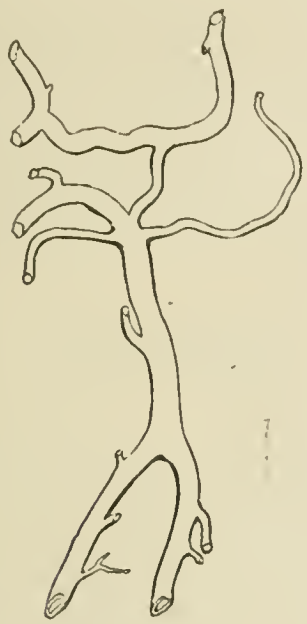


Fig. 1.

anterior cerebral springing off from the right posterior communicating forming an arch, the centre of which would have been normally the anterior communicating. The left internal carotid artery connecting with the left anterior cerebral, while the right anterior cerebral has no such connection. The left posterior cerebral abnormally large, and the right one wanting, as seen in Fig. 1.

The dissection of the scalp was then continued downwards. The greater part of the left temporal bone, with the internal carotid attached, including the external and common trunk, removed. The internal carotid filled with wax emerged from the carotid canal, the injection having descended to within a short distance of the bifurcation. The ligature had ulcerated through the external carotid. Above the seat of the ligature the artery was closed by a clot which completely filled it, showing that the *secondary hemorrhage* came from the *proximate* side of the *ligature*. The ascending pharyngeal immediately above ulcerated through, but pervious; then the continuation of the external carotid, somewhat contracted; below the common trunk of the facial and lingual, as well as the superior thyroid closed by adhesive inflammatory action. These with the clot are shown in Fig. 2.

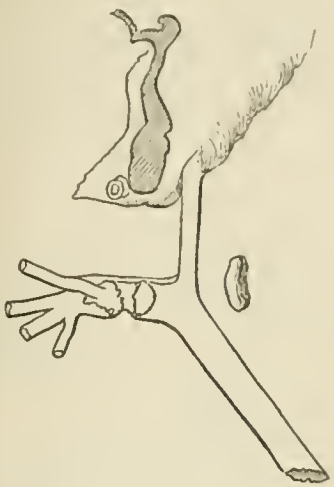

Fig. 2.

The diseased section of the inferior maxilla was then removed. On the right side the arch of the aorta with its branches was dissected upwards; at this stage our further dissection was peremptorily stopped by the representatives of the family, and we were only able to remove the carotid a short distance above the seat of the ligature, otherwise we should have traced its subdivisions, and also removed the temporal bone on that side. The ligature around the carotid was immediately below the superior thyroid, which was also ligatured. Immediately above the latter was a tuft of branches—a common origin for the lingual and facial, and the ascending pharyngeal; then extending upwards the continuation of the external carotid terminated in the internal maxillary and temporal arteries. But, owing to the above-mentioned

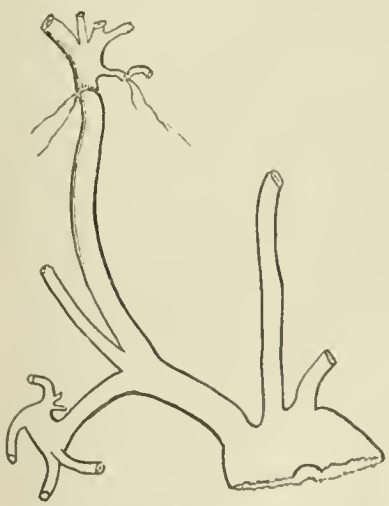

Fig. 3.

contretemps, our complete dissection of this unique specimen was cut short.

The segment of the maxilla included the ramus of the jaw and body as far as the anterior bicuspid

of left side: the ramus much enlarged; the second bicuspid and anterior molar firmly imbedded in their alveolar processes, while the second molar, quite loose, but perfectly sound, was held *in situ* by a shred of connective tissue; the third molar tooth still imbedded within the ulcerated gum, and quite loose. The alveolar process of the second molar entirely absorbed, also the anterior portion of the alveola of the third molar, as well as the lower portion of the posterior section of that of the second molar; beneath

Fig. 4.

the second molar the ulcerated coats of the inferior dental artery. At the upper and inner surface near the base of the coronoid process, two openings in the bone. The inferior dental foramen much enlarged, the inferior dental canal quite enlarged at section.

On the external surface, the bone much thinned and the mental foramen enlarged.

This unique case, although unfortunate in its results, throws considerable light on the subject of the ligature of the carotids, and resolves itself into the following aphorisms:

1. If an accurate diagnosis had been made when the case first came under my observation, removal of the diseased segment of the inferior maxilla should have been attempted.

2. The indications under the circumstances were undoubtedly the ligation of both external carotid arteries.

3. The recurrent hemorrhage, owing to the anastomosis between the middle meningeal (internal maxillary), anterior meningeal (internal carotid) and the lachrymal (ophthalmic) arteries; also to the one between the nasal or spheno-palatine (internal maxillary) and nasal branches of the ethmoidal (ophthalmic) arteries; again to that of the lachrymal (ophthalmic) with the deep temporal branches of the internal maxillary artery. The more remote anastomosis between the temporal (external carotid) and ophthalmic arteries is hardly worthy of consideration—demonstrates that an error was made in not *simultaneously* ligating on *left* side the *internal carotid*, which would have thus cut off the direct current from the basilar to the common carotid artery, thus affording a greater check to the development of the recurrent circulation.

4. In young subjects the ligature of both common carotids can be performed with comparative safety, as the collateral circulation through the vertebrals rapidly compensates the loss caused by the ligation of the former.

5. The mode of procedure adopted by me on the right side, although successful, demonstrates that it is best to seek the bifurcation; yet we would have here made an unsuccessful search for it, and would have been compelled to have placed the ligature at the seat of election, or else to have ligated the artery above the digastricus; therefore above the common origin of the facial and lingual arteries, and below its division into the internal maxillary and temporal arteries.

6. The secondary hemorrhage on left side arose from the cardiac side of ligature, as the distal extremity of the external carotid was completely closed by the clot prior to its removal from the artery. It is barely possible that the anterior pharyngeal may have slightly influenced it.

7. The neuralgia in the inferior dental nerve, controlled by compression of the common carotid on left side, shows that it was caused by the pressure of the aneurismal sac on the nerve.

8. The question arises as to the predisposing cause of this aneurism: was it due to the developments of the molar teeth on left side, inducing an increased circulatory action on that side, which, although anatomically normal, was, owing to the anatomical deficiency on the right side, physiologically excessive?

9. The control of the secondary hemorrhage by the combination of veratrum viride and digitalis demonstrates its value in similar cases; the first through the vaso-motors acting directly on the arterioles, the latter through the pneumogastrics on the heart.

Original Lecture.

A CLINICAL LECTURE UPON CHOREA.

DELIVERED AT THE LONG ISLAND HOSPITAL MEDICAL COLLEGE,

By ALLAN McLANE HAMILTON, M.D.

(Reported by Dr. James H. Shorter.)

Gentlemen:—It will be my pleasure to say a few words to you to-day in regard to a very common nervous affection of childhood. I allude to chorea, which is a disease you will constantly meet with when you leave here. I may safely say that two-thirds of the convulsive neuroses of children are designated by this term. You are doubtless familiar with the appearance of the little patients, but to illustrate my remarks more clearly, I have brought before you two boys, and I want you to examine them closely. They are both badly nourished children, delicate and pale. You will notice the dark, straight hair, thin lips and melancholy expression upon their faces; their brows are knitted, and their eyes sunken. These things strongly indicate a condition known as the *nervous diathesis*. It is among patients of this kind that we find nervous disease. I have seen a great many cases of chorea, but do not think that more than a tenth part of the number were of the blond type; but nearly all of them possessed the dirty-white complexion, cold hands, and rough skin which is accompanied by a phosphatic condition of the urine. Chorea, as the text-books tell us, is a convulsive affection without loss of consciousness, affecting generally certain groups of muscles, perhaps one-half of the body; attended sometimes by paresis, rarely by loss of sensation, and confined nearly always

to childhood. It is comparatively rare after the fourteenth or fifteenth year, and is generally curable.

In adult life, we find it to assume various unusual forms. The patients may roll over and over on the floor, spin like tops, or there may be paralysis with contractions. It is then usually the continuation of some previous attack, dating from early life. I propose to-day to speak more particularly of this neurosis among children. We are told by various writers that it is confined to the period between the third and fourteenth years, although certain authors, Watson among them, limit the time by the first and second dentitions. Dr. Hillier, of the Children's Hospital, Great Ormond Street, has given a table, which is referred to by Radcliffe in Russell Reynolds's System of Medicine. Of 422 cases at the above institution, 104 were between the ages of ten and twelve. Girls seem more often affected than boys, for what reason I cannot say, except that it may be the more delicate organization of the former, and the preparative changes going on before menstruation.

You will form a better idea of the disease if I relate a case. The patient, a boy of ten years, who attends school, becomes irritable, loses appetite, and does not care to go out and play with his fellows. He becomes pale and thin, and sits by himself. In a little while some movement of the hand or fingers, some twitching of the face, or dragging of one foot, when he walks, attract the attention of parent or teacher. He may be punished, with the idea that such movements are the result of bad habits or viciousness, but it does no good, but probably increases the trouble. These jactitations cease at night, when he rests uneasily, and is disturbed by bad dreams. This is the condition you will find the patient in. What is the course of the disease? If you do not treat him properly, or if he is neglected, it will not be long before the convulsive movements become general. The feet may drag along, as if he was paralyzed, and so he sometimes is, for the condition is a gradual one. He will be unable to button his clothing, or attend to his little wants. I have a patient under treatment at present, who presents a condition which is not uncommon, but I have not seen it mentioned in the text-books, as it should be. I allude to the involvement of the vocal cords, and the aphonia which may result. There are other defects of articulation, which arise from an inco-ordination of the lips and tongue. When the case reaches this point, we may consider the condition a troublesome one. Now, gentlemen, I wish to allude to the character of the convulsive movements, and I may begin by telling you that they are always *clonic*. You know that the two great varieties of convulsions are *clonic* and *tonic*, and I consider these terms simply clinical expressions, for it is a great matter of doubt whether there is such a *physiological* condition as a *tonic* contraction. A muscle in tonic contraction presents the condition shown by the electrotonic muscle, and though I may be bold in making a rash statement, I consider such a tonic or tetanic state simply a *very* rapid contraction of the muscular fibrillæ, and the rigid contraction of the limb a gross appearance. I think that the experiment with the tuning-fork will substantiate my assertion. We will, however, use the expressions *clonic* and *tonic* in their clinical sense to distinguish the convulsions. These contractions of the muscles in chorea are clonic; that is to say, there are intermissions of rest between the contractions. They are not increased by an effort of the will, to stop them, as is the case in sclerosis, where the tremors are exaggerated by any attempt of the individual to control them. In certain cases, however, there are exceptions to this rule, and I have often been led to suppose that chorea might be divided into two varieties, viz.: one, in which the movements are increased with the exercise of the will, the other, when they are most violent in a state of rest.* The movements of the hands are characteristic, I think. There is a prehensile movement of the fingers and a rubbing of the ball of the thumb and ends of the fingers. There is swinging of the arm, and a shrugging of the shoulder, as if the patient had on large or uncomfortable underclothing.

A little point that may, perhaps, interest you, and I only speak of it because it is unique: I allude to the habit which these little patients have of rubbing the seam of the trousers' leg by the hand which is affected, for these movements often go on most actively when the arm hangs by the side, and when the attention is not directed to it. In other diseases just such "little straws" will give you a serviceable hint once in a while. Take, for instance, commencing paresis of any kind of the lower limbs. If you look at the tip of the shoe you will find the sole worn down on one side of the body. In locomotor ataxia you will discover a reduction of the heel. When these little patients are worried or embarrassed the movements are greatly increased, and you must bear this in mind in your subsequent management of the case. The urine is generally neutral, or else it contains dense clouds of the phosphates. It is passed in the majority of cases in great quantities.

Now, I wish to say a word about the etiology. It is the general opinion that chorea is nearly always associated with cardiac or rheumatic troubles. Romberg, Hughes, and West, besides many others, have so decided; and when we consider the pathology of the disease it will appear to us very reasonable. Of 104 cases of chorea at Guy's Hospital, but 15 of the number were free from any indication of cardiac or rheumatic difficulties.

It often follows scarlatina or other zymotic febriculæ, or takes its origin from an attack of acute rheumatism. The oldest of these boys first went through scarlet fever with kidney complications, which were unusually severe. The disease may result, and generally does, from some directly exciting cause, such as over-study, bad air, or food, or sudden fright. My recent investigations in regard to the occurrence of the disease among school children revealed the astounding fact, that over 20 per cent. of young school children of the public schools of New York were affected with choretic affections of greater or less gravity. West expresses it as his opinion, that over-study is a common cause, and my investigations more than prove this. I will allude, *en passant*, to a cause which is often overlooked. I mean want of exercise, and eating between meals. The confectioner is one of the worst enemies of the practitioner who treats nervous disease.

In regard to the pathology, I can only say, that a great number of observers believe the disease to be a functional one, and a few take the view which I believe to be the right one, viz., that the disease is organic. Hughlings Jackson, an able investigator, considers the lesions to be located in the corpus striatum, where small thrombi plug up the minute vessels. The microscope has proved this. Some writers have raised the question in regard to the existence of the hemi-chorea on the same side of the body as that of the brain where the lesion is found, and contend that there must be crossed action. Broadbent opposes Hugh-

* In a recent conversation with my friend Dr. S. Weir Mitchell, he remarked that he had often recognized the necessity for such a division.

lings Jackson to some extent. Now, it is easy to see how these plugs may come from the heart. A condition of this organ has been witnessed by some observers, where fibrinous masses were adherent to the chordæ tendinæ and chordæ columnæ. These little shreds may be detached and carried up in the circulation. They are really small emboli. As to the inconsistency of the hemichorea occurring on the same side as the lesion, I do not think it is at all impossible. Dupuy and Brown-Séquard have made experiments which prove that such a condition of affairs may exist—and I have myself done the same thing. Since my experiments, I have heard of a case, related by Dr. Walter Hay, of Chicago, in which post-mortem examination revealed a cerebral hemorrhage on the side of the hemiplegia. I have before said, that clonic convulsions are those of the disease under consideration. Now, I wish to tell you, that this variety of convulsion, like tremor, is due to an interruption of nervous discharges, and a point of irritation at the seat of origin of motor impulses. It is very probable that there is trouble also in the nerve trunks. Ellischer has confirmed this in describing the degeneration of certain nerve-fibres in a case of chorea that recently died from some intercurrent disease. Schmidt calls attention to an explanation he gives. The origin of the neurosis, he says, springs from anæmia in the first place, and, secondarily, spinal irritation, which he suggests is symptomatized by the painful points which are found in the spinal column. It is undoubtedly a sensori-motor disturbance, due to insufficient nourishment of nerve-tissue; and that is enough for us to know.

Fatal cases of chorea are rare. Hughes and Bastian have both collected cases, most of which presented extensive changes in the nervous substance. Lately, Ellischer has given us an account of a most interesting observation. The vascular changes in the brain were marked, the walls of the vessels being changed, and the surface covered by dark granules. In certain places the calibre of the vessels was narrowed, and there was an accumulation of blood-corpuscles, and consequent effusion of the watery parts of the blood. Some of the vessels contained coagula. The connective tissue about these vessels was thickened and increased in size, and contained yellow pigment and granulated nuclei. The large ganglionic cells in the brain were filled with pigment, and the cell contents much changed. Sections of motor nerves exhibited red patches, and destruction of nerve-fibres. These changes show, then, great vascular alteration, and degeneration of normal nerve-tissue.

The PROGNOSIS is generally good. A case of acute chorea—and I consider it to be one that has not progressed more than a month or two—should get well with proper treatment in about the same length of time; but you will generally meet with the chronic type of the disease, and will then have your hands full—and will be lucky if a cure is wrought in five or six months.

These cases rarely die from the disease itself, but either outgrow it, or end their days by some other disease.

In the matter of diagnosis I have very little to say. I do not think chorea can be confounded with any other neurosis. You will have to make the differential diagnosis sometimes between it and tremors of various kinds—but there will be no trouble—the movements are characteristic. What I have already said about sclerosis you must remember. You must also know that certain irregular movements may be simply bad habits, also that certain limited convulsive twichings are found in connection with ascarides.

It is important and difficult sometimes to make a diagnosis when chorea follows hemiplegia, or is associated with other organic neuroses. A condition called *athcotosis* by some writers I believe to be a choretic state, and various neuroses of the convulsive kind, now designated by different titles, I am sure are nothing but varieties of chorea.

A peculiar form of hemiparesis must be differentiated from the hemiplegia, cerebral hemorrhage or other brain lesions; but these are uncommon affections, and slow to disappear, while the hemiparesis of chorea is amenable to treatment and follows the choretic movements, and passes away in a comparatively short time. I wish to tell you of an interesting case, with a peculiar complication, which might mislead one in diagnosis. The patient, a boy of ten years, was brought to me by his father for treatment, after having been seen by many practitioners, who did not agree in regard to his condition. I saw that his movements were choretic. Questioning revealed the fact, that he had never been a strong child, but had always been disposed to nervous troubles; even the exanthematous fevers, which, like other children, he had had, were generally connected with stupor, and other evidence of susceptibility of the nervous substance to blood-poison. He never had any rheumatic nor cardiac affections, and I could hear nothing to indicate valvular trouble. The heart sounds were sharp and quick, however. Four years ago he began to decline, became weak and anæmic, was irritable, moody, and bad-tempered. His appetite was capricious, and he preferred candy and sweets to more solid food. In the summer of 1872 the movements in the hands and arms began, and soon became general. His rest was uncomfortable, and he started up in his sleep and cried out. When I saw him four months ago he was a pitiable object. His movements were general. He was unable to hold anything, and was powerless to perform any voluntary action, except those of a general kind. He could not unbutton his clothing nor put on his cap. His mother even had difficulty in making him walk.

Variety of Movement.—Head was violently agitated, there being contractions of the sterno-cleido-mastoideus. He "sucked in his cheeks," and pursed up his mouth, smacking the lips. Other facial contortions were violent. He winked spasmodically, and there was constant motion of the eyeballs.

The arms were in constant motion, but the right was not affected so much as the left. The right arm and hand were slightly paretic, and he was able to force the column of fluid in the fluid dynamometer * up to 16°, which is equal to 15 lbs. pressure to the square inch. The left forced it up to 18°.

The legs.—The right leg was also slightly paretic. The toe of the shoe was worn down to some degree, although the walk was not noticeably affected.

There was an uneasy rolling of the pelvis when he sat down, and the legs were not entirely under the control of the patient. There was pain in the wrists and ankles. Under proper management of his diet he gradually improved, and at the last visit was nearly well. I noticed then for the first time the following peculiar state of affairs: When sitting in front of me, I told him to raise his hands, one after the other. The right hand he raised promptly, but the left he could not, unless he took hold of the wrist with the other hand, and lifted it up. This condition struck me as remarkable, particularly as he had to repeat the process of aiding with the right hand. Several neuroses

* Described in Psychological and Medico-Legal Journal, April, 1875.

might explain the condition, however, and I proceeded to eliminate them in the diagnosis.

1st. *Paralysis.*—The left hand and forearm might be paretic. There was no loss of electro-muscular contractility, however, but, if anything, it was increased. The muscular power, tested by the dynamometer, was found to be even better than in the other hand. There was no atrophy. With these facts in view, it seemed improbable that this should be the cause.

It was found that when the other hand was held down, the boy was then able to lift his left hand unassisted, and even to raise a dumb-bell weighing 10 lbs., but so soon as the other hand was released he was unable to repeat it.

2d. *Habit.*—To determine whether this was the result of any bad habit, I ascertained from the father that his son had never used one hand to lift the other till a few weeks ago.

3d. *Central changes.*—I have been forced to accept the theory that there is some central trouble, or else some change in the nerve itself affecting its conductivity, although the absence of sensory or motor disturbance (the limb being neither hyperæsthetic nor anæsthetic, and there being no loss of motor power, but, on the contrary, greater muscular excitability) would contradict this. As we know, one of the first signs of certain central troubles is this very marked electro-muscular contractility. The only hope for diagnosis rests with the advance of time, when, if central disease exists, it will manifest itself by other symptoms. If this is not the cause of the disease it is very probable that it may be hysterical.

We will now speak of *treatment*, and this, perhaps, is of more importance than anything else of which I have spoken, and in giving a list of drugs I will exclude a great many remedies that have been used with indifferent success, and only allude to a few, in the order I believe them to stand in point of efficacy:

Internal remedies.	Strychnia.	
	Arsenic.	
	Iron in its various forms (bromide, carbonate, etc.).	
	Phosphorus.	
External remedies.	Cold to spine.	Ice.
		Ether spray.
		Cold douche.
	Russian or Turkish baths.	
	Salt baths.	

Rest, diet, fresh air.

Some of these may be combined with good effect. The plan of treatment I generally employ is the following: Should the child be "run down," as is generally the case, I begin with some preparation of iron, and administer at the same time cod liver oil. As regards special treatment, I find strychnine serviceable carried up to the point where stiffness of the sural muscles is arrived at. Next to this I consider arsenic to stand. It must be given in large doses. You will occasionally find that digestive troubles are produced very quickly by this drug, and then strychnia may be substituted. Cold to the spine cannot be overestimated as a plan of treatment. You may either use the ether spray, which was first suggested by Subetski, of Warsaw, in 1866, or apply ice-bags every day, allowing them to stay on about ten minutes. Perrond, who has used the ether spray, makes applications from four to eight minutes in duration every day. Of thirty-five cases I have treated in this way (I mean with the ether spray) from fifteen to twenty applications produced permanent benefit, and here I would say that the spray should be directed to the upper part of the cord, over the upper cervical vertebræ. Eserine has been lately recommended, and Bouchut has given the results of 437 cases, 205 who took it in pilular form, and 232 hypodermically. Eserine is the alkaloid of Calabar bean. The average dose was from two to five milligrammes. He obtained temporary benefit, which seemed to wear off; but when the drug was repeatedly administered he accomplished many cures. He reports twenty-three cures, by an average of seven injections. It is a dangerous remedy, however, and produces severe gastric symptoms.

The salts of zinc have occasionally proved valuable in cases of this disease, but I prefer the remedies I have mentioned. Conium is occasionally efficacious, but its effects are temporary. I must say, before going further, that I have found phosphorus, with cod-liver oil, to be a most valuable curative agent, and in cases where everything else failed, it has succeeded. This seems reasonable, when we consider how much impaired must be the nutrition of the nervous matter. Now, gentlemen, you will find instances where nothing does good. Put them in a dark room, and keep them perfectly quiet. You will be often astonished at the result. Weir Mitchell has written of the value of this treatment, and I refer you to his lecture. There are little things that must be watched. The diet, above all things, should be regulated with judgment. Plenty of fresh air and sleep come next, and absolute mental rest must be enforced. The school books and the school room are to be parted from, and agreeable diversions planned. An excellent auxiliary to your medication is the salt bath. A handful of rock-salt in the water, and the energetic use of the rough towel, will infuse a tone and vigor that will soon become apparent. In conclusion, I must tell you that decided medication is useless in these patients when their personal habits are not looked after; but if you will start them upon the right track, and afterwards give the medicines I have named, you will have the satisfaction of generally curing your case, and covering yourself with glory, for the cure of chorea is considered by the friends of the patient to be a great triumph.

NEW YORK, *Jan.* 18, 1876.

Progress of Medical Science.

ARTHROPATHY IN A CASE OF LOCOMOTOR ATAXIA.—M. Bourceret recently reported the following interesting case to the *Société Anatomique*: A middle-aged woman entered La Charité on April 8th, giving a pretty well-marked history of locomotor ataxia, that dated back ten months, and affected the left leg particularly. Three days later her left thigh and buttock suddenly began to swell. The swelling reached its maximum in a few hours, was hard, not truly œdematous, not painful on pressure, and ended abruptly at the knee. There was no fluctuation. The affected parts were double the size of those on the opposite limb; the leg was shortened, and the foot slightly rotated outwards. There was also a certain resistance without tenderness in the left iliac fossa. The swelling disappeared almost entirely in a week, and about this time vaginal examination discovered a round, smooth, hard, fixed tumor, apparently springing from the pelvic bones in the left side. Soon afterwards pus was detected in the sheath of the psoas, above and below Poupart's ligament. On May 3d the left knee began to swell, with symptoms of great prostration, and death took place on the 6th.

On the autopsy pus was found disseminated between the muscles of the thigh, especially on its external and posterior aspects. The pus had also perforated the sheaths of some of the muscles, separating but not destroying the fibres—a proof that the effusion had taken place with great rapidity. Anteriorly it had perforated the sheath of the psoas, and made its way into the pelvis, where it was infiltrated between the fibres of the iliacus. The capsule of the hip joint was much thickened, contained some calcareous concretions, and was perforated below and behind. The borders of the cotyloid cavity were eroded behind and below. The head and two-thirds of the neck of the femur had disappeared, the inner surface of the neck being smooth and slightly eburnated. There were no osteophytes about the neck or great trochanter, but on the contrary in some places there was rarefaction of the bone. When the capsule was opened the femur was found to be luxated backwards, the enlarged capsule allowing the luxation to be easily produced, and as easily reduced. The left knee was distended with pus, and the cartilages were eroded in spots. The right hip-joint was unaffected.

On laying bare the cord, a small fibroma, about the size of a pea, was seen on the right posterior lumbar roots. The posterior roots on both sides were completely atrophied as far up as the cervical region. They had a yellow color, and were very vascular. In the lumbar and inferior dorsal regions the median posterior columns were gray, hard, and apparently composed wholly of sclerotic tissue, while the lateral portions of the posterior columns, though degenerated, were soft, and of a reddish-gray color. The lesion gradually tapered off towards the cervical region, where only the median posterior columns were affected with the reddish-gray degeneration.

In the discussion that followed, M. Charcot called attention to the wonderful rapidity with which the lesions of spinal arthropathy are produced. He mentioned a case which had been under his own charge, in which the humerus had been destroyed in the short space of three months. In his case, as in that of M. Bourceret, the destruction was like what would be produced by rubbing a bone on a grindstone. This rapid destruction of bone is habitual in and peculiar to the arthropathies of ataxia. There seems to be in these cases a peculiar abnormal condition of the bone, which favors their rapid destruction. Spontaneous fractures are, it is true, very frequent in ataxics, but in this instance it was of no importance whether there had been a fracture or not. The pressure of pus in this case was exceptional, but it had been observed now in three out of about fifty cases. A dry arthritis might in these cases be transformed into a purulent arthritis.—*Progrès Médical*, Oct. 9, 1875.

Hæmoptysis Treated with Ergot.—Dr. Jas. M. Williamson has made a fair trial of this drug in the treatment of fifty cases of hæmoptysis, and with encouraging success. The ergot was given invariably by the mouth, and in the form of the fluid extract. Forty-minim doses may be administered twice within the first hour, and guided by the results, at least every two hours afterwards, the dose being diminished and given less frequently as the hemorrhage subsides. No disagreeable effects were observed to follow, even when large doses were given at short intervals; but, he says, that if four or five full doses make no distinct impression upon the hemorrhage, the remedy should be abandoned for another. This treatment proved ineffectual in only six out of the fifty cases.—*Lancet*, November 13, 1875.

Syphilitic Phthisis.—Fournier sums up in the following four axioms the conclusions he has reached on this subject:

1. Tertiary syphilis can produce in the lungs lesions which, either locally or by reacting on the general health, simulate pulmonary phthisis.

2. These pulmonary lesions of syphilis are often amenable to specific treatment; however grave and important they may appear, they are far from being always beyond the resources of art.

3. Consequently, when a case of pulmonary lesion presents itself, it is important, unless the existence of tuberculosis be quite certain, to ascertain if the lesion can be traced to syphilis. It is necessary always to bear in mind that syphilis is a possible cause of pulmonary lesions.

4. When syphilis can be suspected to be the cause, the primary indication is to prescribe specific treatment, which in similar cases has sometimes been followed by the happiest results.

In making a differential diagnosis, Fournier relies mainly on the syphilitic lesion being unilateral, circumscribed, and without predilection for the summits of the lungs. It generally affects a portion of the lung not more than a few centimetres square, constituting a little islet of disease surrounded by healthy lung-tissue. When the morbid changes are far advanced in this circumscribed spot, the diagnosis of syphilis is pretty safe. The co-existence of a fair degree of health and *embonpoint* with advanced pulmonary changes, points to syphilis as the cause of the latter, as does also a slow development of the pulmonary lesion, the general condition remaining good. Of course, a close examination of the entire body for the ordinary symptoms of tuberculosis or syphilis must never be omitted.

There is no hereditary transmission of pulmonary syphilis.—*Gazette Hebdom.*, Dec. 17, 1875.

Removal of the Entire Right Parietal and Half of the Frontal Bone.—Dr. John R. Hayes reports a case, where, after a severe burn, these bones were exposed. About five months after the injury the patient presented herself, complaining "that the bones of the head were falling off." The right parietal and half the frontal bone were found separated from those of the opposite side, to the extent of about an inch, and slightly movable. At first no interference with them was made, serious results being feared. On the third day, however, the bones having separated a little more, the whole parietal and half the frontal bone were removed. The inner surface was covered with a thick curdy matter, and the depressions for arteries, etc., obliterated. The surface of the dura mater was covered with florid granulations, and a quantity of fetid pus came away. On making slight pressure on each side of the head, "a quantity of pus welled up from between the hemispheres." The patient felt no inconvenience, neither headache nor any other cerebral symptoms. The surface was washed with a weak carbolic acid lotion, after which water dressings were applied. In ten days it was changed to zinc dressings. The surface occasionally bled from the slightest touch.

Two months after, skin was grafted on the surface of the granulations at four different places; three became attached and the other fell off. Four months after this the patient seemed to be quite well. New skin had grown nearly over the entire of the exposed surface, and she was able to attend to her ordinary duties without complaining of any pain.—*The British Medical Journal*, December 25, 1875.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

HOSPITAL CONSTRUCTION AND ORGANIZATION.*

III.

HOUSE-PIPES enter so much into structure, as to demand our next consideration.

While some drain-pipes are needed under basements to secure dryness, and if carriers of water only are not liable to get out of order, if properly laid, all other pipes should not be under the buildings, but be arranged so as to be as accessible as possible. The greatest pains must be taken that all water-pipes, heat-pipes, gas pipes and soil-pipes connecting with the buildings, be made as impervious as possible. Direct experiments have shown how few materials are impervious to air. Besides, sewer gases act upon many metals, and cause such corrosions as increase porosity. We have recently had sent us a specimen of pipe lined with glass, which has been in successful use, and seems to secure that impermeability which is desirable in house-conduits, and that smoothness which prevents adhesion to the surface. It must be remembered, too, that all pipes, unless very closely compacted with the structure through which they pass, on their outside, form special capillary air-conduits. The heating apparatus, especially, is thus liable to become a mixer of the air of different wards, if one apparatus is used for all.

The method as to sewer-pipes is thus given by our authors: Dr. Billings (p. 43) speaks chiefly of plans for ventilating sewers, and recommends shafts rising above the buildings, but not connected with any of the aspiratory chimneys. Dr. Folsom alludes to them only incidentally. Dr. Jones (p. 111) has the house sewers discharge into two main sewers on the hospital grounds, the former being not less than two feet, and the latter four feet in diameter. These to be ventilated, and all water used for culinary and bath purposes to flush the water closets and empty into the main sewers. He also proposes a system of fountains on the grounds, the waste water from which should flow into the sewers. Dr. Morris (p. 223) would have every water-closet separately trapped, and every pipe carrying soiled water furnished with traps. The main sewer should be outside the grounds, as suggested by Dr. Folsom as to the main drain. To prevent reflux of air from this "sewer" into the "drains," a connection should be made with the furnace of the steam-heating apparatus.

The spouts collecting the water from the roofs should fall into the sewers, these openings, when not stopped by water-flow, serving as ventilators. Other drain-pipes should connect with flues, opening above the roofs. Drainage and sewerage are spoken of as if the same.

Dr. Smith has very little to say as to methods of carrying off the waste-water, but in reference to the risks of sewers, advocates ground ventilation (p. 228), by means of a heated shaft communicating with drain-pipes and conduits. He would have the more superficial conduits porous, and would so ventilate and warm the soil as to draw gases from the ground into them, and discharge them above the buildings.

Dr. Niernsee (p. 336) provides that no soil or water-pipes should pass under hospital buildings.

We beg to suggest that it would be better if we could confine the name "drains" to tubes for the carriage of surface and sub-soil water, and regard all water contaminated by ablutions, by fecal matter, or by any of the offal incident to dwellings, as to be carried by pipes known as sewers, soil-pipes, or wastage-pipes. The terms "main sewers" and "house-connections" are sufficiently distinctive, if "soil" pipes, to some, confuse the idea of ground soil and fouled water. We believe, with S., that water-closets, baths, etc., should be, as far as possible, separated from other buildings. The laundry furnishes a large amount of impregnated water, and the soaps used in washing, not only, by their decompositions, add to the impurity, but help to befoul the sewers with adherent matter.

Flushing by the water from the roof spouts failed us in a fair test of three years' duration. In quick rain-fall, the air is so rapidly displaced (Parkes' Hygiene, p. 349) as to break or exhaust the traps. The emptying of fountains into the pipes opens ventilators at points not desirable, and will be of little service. It is doubtful whether any of the water-traps are successful, and whether foul water even, when not emptied by suction, is a good interruption to gases. Dean, of Rochester, after careful experiments on his own house, discards them. (See Health Asso., 1875.)

Ventilation of sewer-pipes by means of heat must be well guarded, for heat is a promoter of decomposition. The caution of Billings is good as to the separation of sewer ventilating shafts from aspirating

* HOSPITAL PLANS. *Five Essays Relating to the Construction, Organization, and Management of Hospitals.* Contributed by their Authors for the Johns Hopkins Hospital, of Baltimore. New York: William Wood & Co. 1875. 8vo, pp. 355.

chimneys. Down currents sometimes are detected, even where fire is adjacent, especially as to descending flues. "Eckstein on Chimneys," gives important cautions. The size of ventilating shafts must be nearly that of the soil-pipes themselves. They are of little account if left to natural ventilation.

We believe a complete separation of connection between house-pipes and main outside sewers is the only feasible plan. Each house sewer-pipe can in this way have only its own relation to the building and to the main, and thus concentration of poisons can be prevented. The excellent paper of French, on Drainage (Mass. Report, 1873) also alludes to house-sewerage, and gives a most excellent method of sewer separation. The last Report of the Board of Health of the District of Columbia also well illustrates some of these points. This outside method of breaking connection admits of airing and disinfecting and filtering. The pipes between the house and the main should be so vitrified or glass-lined as to prevent adhesions on the inside, and should be flushed each day with some disinfecting solution. We have much to say as to preference for the dry system for much of hospital excreta, but here must confine our remarks to pipe construction.

The only plea for sewer-pipes of two and four feet diameter is that they admit of inside patrol. A pipe of too great calibre does not cleanse itself as well as one adapted to the amount of waste to be carried (see French, etc.). We would have also two continuous pipes from each ward, laundry and kitchen receptacle, so that as often as need be one might be shut off and flushed with air and gaseous disinfectants, or cleansed by an inside piston. We believe the time will come when the various pipes that enter into house construction will be so arranged as to admit of direct police, without removal of ground or floors, so that any defect may be prevented, and after cleansing by flushing, the parts may be swabbed out.

Next to the consideration of structure, we come to consider the relative arrangements of the buildings and of the various parts, each to the other.

It is at once agreed that no building shall rest directly upon the ground. There are some reasons why a military plan should in some cases be adopted, and parts be located on arches three or four feet high, without excavation. Thus we secure a well-drained and well-aired ground surface, just like that of the surrounding soil. Floors, such as we have noticed, may be filled between the under-beams with brick or cement, supported on an open iron frame, or by an extra underboarding, and the porousness of side inclosure is easily insured. Thickness of inclosure here, as elsewhere, comes into consideration.

If, as is usual, a basement or cellar be advocated, we must be careful to define it before we assign its utilities. A basement with drains, so as to care for all surface water and keep all ground water at least six (6) feet below (S., p. 277) the surface, with areas to the outside walls, and space and air ducts below (N. p. 333), and with only two or three feet of a high-ceiled basement below the surface, is not the underground base concern which it is popular and proper to taboo prodigiously.

The basement of Billings, p. 27, is 9 feet high, all above ground, floored with asphalt and heated and ventilated. That of Folsom, by plan, must be at least 8 feet high, with 5 feet in the clear above ground, and duly asphalted and dried below. That of Jones (p. 163) is 12 feet high, with a good share above ground level. The basement of Morris (pp. 195 and 220) is "lofty," with large windows and as well-lighted, well-ventilated, and well-finished as any other part of the building, with vaults and cellars beneath, made as dry and airy as possible. The floor of the basement has imported Portland cement walls, with hard-polish plaster. If any part of it by grade is brought below ground level, there is to be a wide area, with sloped embankments. The basement of Smith (p. 298) is 6 feet above ground, with double-aired side walls, asphalt and concrete floor and under-drainage in the deepest perfection of the art.

We rejoice with much joy over good foundations, and feel glad that such attention is bestowed by our authors upon the beginnings of the great uprising. But we demur a little from calling such structure a basement, unless we reject the definition of Webster, "a story below the level of the street," and accept that of Worcester, "the first story on which the main order of architecture rests." We believe in just such first-story structure, but such basements can be made far more available than most of our authors suggest. We do not wonder that Dr. Morris assigns at least *mania à potu* to one of these basement rooms, and has in one end a dispensary (p. 251), although afterward insisting that second or (really third stories) are healthier than those below. Such sub-structure is suitable for reception wards, for walking patients, for some forms of disease, and for various administration purposes. Much of the question as to two-storied structures above depends upon the estimate put upon such apartments as these. We should certainly never think of putting a double tier of wards, making a height of forty feet, without attic, above such high basements as these. Clean ground is not so unwholesome a thing. If we are to have such lofty substructure we should surely utilize it after the plan of Dr. Jones (pp. 163, 164), with exception of laundry and some minor alterations, and should so far carry out the ideas of M., as not to need his second (third) storied ward.

The question as to whether the buildings shall be erected for temporary or permanent occupancy, and the allied, although not the identical question, whether they shall be of single or successive stories is, as it well may be, prominently considered by our authors. We find the most of them laboring under that confusion of terms, which of late years has found its way into hospital nomenclature. The letter of the trustees speaks of "the choice between the *pavilion* system,"

which admits of two or more stories in height, permanently constructed, and "the *barrack* system, of one-story structures, destructible in whole or in part." B. very wisely uses the terms temporary and permanent hospitals as the only ones having definitiveness, and considers the question of number of stories as distinct from that of length of occupancy. Yet afterward, in the use of the terms, "wooden barracks," "barrack hospitals," "one and two story pavilions," he gives currency to these loose nominals.

Dr. Folsom (p. 26) speaks of pavilion wards, but, we are glad to see, usually avoids the modern terms. Dr. Jones (p. 113), while using the words temporary and permanent, as a heading, speaks much of destructible wooden pavilion hospitals, of the pavilion system, of temporary pavilion hospitals, etc. Dr. Morris (p. 178), while guarding against the application of the terms pavilion and barrack, as not distinctive of one or two story, or destructible and indestructible structures, proposes the terms "City Hospital," as denoting permanency. Yet he also bows to custom, and speaks of "temporary barracks and hut hospitals," of "pavilions of two-story elevation," of "separate pavilions," and of "pavilion wards." Dr. Smith (p. 291) quotes the faulty definition of Miss Nightingale, who describes a pavilion "as a separate detached BLOCK of buildings, or separate detached hospital, with as little connection in its ventilation with any other part of the hospital as if it were really a separate establishment, miles away." He says (p. 292) that a pavilion may be a tent or barrack, and may have one or many stories. Niernsee (p. 336) speaks of the "pavilion system of temporary barracks, and permanent pavilions," and says, their complete separation, as well as the number of stories, is still an open question. Here is great tribulation of nomenclature, which our essayists have not originated, but which, as representative men, they have a right to throw off as "impedimenta."

A barrack, in comparison with a tent, is the military word for permanency, just as of old the temple was more permanent than the tabernacle. In hot climates it would be a wooden structure, to be torn down if convenient on taking march; but in colder climates it was left behind, while the tents were moved on. In this vicinity are large brick structures, erected one hundred years ago, in which the British army quartered. They were called then, as they are now, barracks. The two-story Stone Barracks, of Fort Reily, Kansas, are not movable structures.

When the plan of wards, in wings or as offsets, from the main building came to be discussed, the terms "pavilion," and "block" crept in to denote this *isolation*. For asylums, the term "cottage system" was similarly employed. Now, the real idea of pavilion is something "light, temporary, evanescent." It was the Latin term for butterfly, and had before that application to light and movable encampments. The pavilions of darkness (2 Sam. 22: 12) were clouds. The pavilion which Benhadad feasted in (1 K. 20: 12) was a tent or booth (Keil and Bertheau). When Nebuchadnezzar spread his canopy (Jer. 43: 10), or (A. V.) pavilion, it did not mean an offset to a main building. Its use in architecture, to denote a turret or such insulation, as Gwilt and Brande describe, do not justify its present application. Addison's "royal pavilion" was a tent, and the "field pavilioned" of Milton was a tented field. Let us forsake the innovation, and talk of temporary and permanent hospitals of isolated and aggregated wards; of one or many storied structures, as the case may be.

It is to be borne in mind that this hospital is to be a hospital for the more serious sicknesses. In other words, the convalescent hospital, which, as suggested by F., may also rightly accommodate a class of comfortable incurables, makes the sickness in this hospital more grave. The classification of S. (p. 360), as taken from Bellevue, of 242 able to go up-stairs, 100 to walk about the wards, and only 99 in bed, will not do here. The kind of arrangement needed is modified by this consideration. We hope that the convalescent hospital will be so situated as to be readily accessible by special rail cars for invalids from this hospital, and so admit of easy transfer. And it must be borne in mind that it is equally important as this one to the Medical College. The student needs to study the modified conditions of chronicity and of convalescence, and also to study the physiology of such subjects as well as the intenser pathology. If we are to be patients of any of these gentlemen, we prefer the student who spends in his preliminary course twice as much time on these, as upon the curiosity cases or severer cases. Close clinical observation here gets its first, best start, and prepares for those intense studies which belong to intense cases, and to such maladies as will be seldom met in practice.

Then, again, inside arrangement and height of structure must be made subservient to questions as to classification of disease. The experience of each year is making more definite the lines of demarcation between diseases, and teaching us not only their separation, but that different forms of disease need variation as to surroundings and appointments.

The controlling idea as to the size of wards is regulated much by relative considerations. With the necessity of wards for colored people added to the classification of disease, it is quite apparent that in a hospital of 400 beds, in order to isolation, not many wards will need to be large.

Entire separation of males and females is also insisted upon, but as such a hospital can only be conducted under close discipline and constant personal presence, we see no reason why, in bed diseases at least, the same ward should not be occupied at one end by women, and the other by men, so long as there is a proper cross screen, and passage from one part to another is prohibited. The need of disease classification is recognized by all our authors. A sentence from B. (p. 14) well shows how much questions of inside ar-

rangement turns upon this. "If men affected with rheumatism, disease of the heart, organic disease of the stomach, and paralysis, are placed together in a ward, the danger of hospitalism and infection arising among them is exceedingly small."

A CURE FOR "INCURABLES."

An attempt is being made to establish in this city a hospital for the cure of chronic and intractable diseases. No one is prepared to say on general principles that such an institution is not very much needed here, that it would not have a wide field for usefulness, and be gratefully patronized by a large number of pitiable sufferers. From the recent circumstances, however, which have attended the inception of the enterprise we are inclined to the opinion that the time has not yet arrived to give a practical turn to the sympathies of the profession and of the public. We have no right to question the motives of any medical philanthropist who believes that he is to be the special instrument in the hands of God of working out the salvation of a hopeless class of his afflicted fellow-beings; charity for the humanitarian instincts of our profession places such motives beyond the pale of criticism. Neither do we desire to doubt the special skill of any one who openly and defiantly boasts of extraordinarily brilliant results in the treatment of desperate cases.

The history of all great discoveries teaches us to be cautious in the premature expression of opinions concerning such matters; not to condemn genius in any shape, whether it discovers the circulation of the blood, the principle of anæsthesia, the cure for hydrophobia, the protective power of vaccination, or a new treatment for asthma, chronic rheumatism, and other so-called incurable diseases. New ideas are the landmarks of progress which are offered to us by the benefactors of our race, and cheer us in our toilsome journey toward the goal of therapeutical perfection. All we ask, however, is to have any novel claims properly substantiated by some few significant and telling facts. This is the principle which as impartial students of truth we have a right to discuss in connection with the prospective establishment of this new hospital. The projector of this charity has conveyed the impression, in an article published in full in one of the secular papers, and previously read before one of our medical societies, that the profession did not understand how to treat certain chronic diseases, and that their cure has been a lost art which he had been fortunate enough to discover. This is all very well; and if he can substantiate his claim by scientific facts, he is entitled to the respectful consideration of those of his brethren who are anxious to learn of his method. He leaves us, however, with the simple assumption that we are ignorant of the principles upon which his treatment is founded, and fails to fulfil the promise made in his paper to further enlighten us. In fact, he gives us to understand that he is not prepared to publish his methods to the scientific world until he shall have a hospital where these methods can be demonstrated. With a few who might stoop to question the motives of such a publication in the public prints, the suspicion might arise that this was a case of medical advertising in its most glaring form. But from the fact that any objections which were urged against his course came, as he says, from only such of the few who belonged to the younger and uninitiated members of the profession, it is perhaps not worth while to consider them. We may, however, for the sake of the laudable motive of establishing a hospital for the cure of these so-called "uncurable" diseases, and enlisting the favor of the public in behalf of his project, excuse this flagrant violation of the Code, more especially as his endeavors have since been endorsed by a large number of the most eminent men in New York, who have signed his petition, and thus recognized his superior skill.

Upon this medical endorsement hinges the ultimate success of his undertaking. In fact, this certified approval by the most "eminent medical men" here, carries a weight with the public which no one can question; and while it tacitly acknowledges that the profession, as a whole, are ignorant of what they should know, it commends the projector of the new hospital as a gentleman of superior fitness for his work. This is certainly a very flattering compliment, and well worth the trouble of obtaining the signatures.

In due time a call for a public meeting to consider the feasibility of the hospital project is made, signed, among others, by Drs. Marion Sims, E. H. Davis, Mark Blumenthal, and Joseph Wooster, and the meeting is held. The clergymen who were present, and who made addresses upon the occasion, very properly commended the movement from a humanitarian point of view; but the medical responsibility of the affair was thrown entirely upon the "eminent medical gentlemen" who had so cordially endorsed Dr. Hartt as the right man in the right place. Chancellor Crosby gracefully and prudently acknowledged that he could take no responsibility in deciding the medical merits of the movement; but when he saw such names to the petition as those of Alonzo Clark, Gurdon Buck, and Chas. A. Budd, he felt himself safe in following their lead. The Rev. Dr. McGlynn, who also spoke upon the subject, said, in substance, the same thing, and so the leaders of the medical profession are likely to have all the credit that belongs to the inauguration of so pretentious an enterprise. The expediency of signing the document is, on a question of principle, open to some discussion. We have been led to place such implicit reliance upon the judgment of some of the medical leaders in this city, that we hardly thought it possible for them to be so ready to write their names to a document which on its face was a reflection upon the skill, learning, and capabilities, not only of themselves, but of the entire profession of medicine of this city.

Having entered our protest against this careless man-

ner of writing certificates, so common even with our best men, we ask them in the name of the great body of the profession whom they have the honor to represent, to use in future that prudence in the discharge of their responsibility, which we have a right to expect of them.

Reports of Societies.

NEW YORK COUNTY MEDICAL SOCIETY.

Stated Meeting, January 24, 1876.

DR. T. A. EMMET, VICE-PRESIDENT, IN THE CHAIR.

ON GLEET, AND ESPECIALLY ON ITS RELATIONS TO STRICTURE OF THE URETHRA.

THE President of the Society, DR. H. B. SANDS, read a paper upon the above subject, chiefly for the purpose of exciting discussion. The word gleet was used with a restricted meaning, and was regarded as indicating an imperfect or chronic gonorrhœa. The existence of other varieties of gleet, however, was not denied. A brief outline of the symptoms commonly attending this affection was given, and brief reference was also made to the methods of treatment employed for its cure. The pathology of gleet was next considered, and the opinion expressed that many surgeons have presented views which are exclusive and erroneous. In the first place, bearing in mind the sense in which the term gleet is used in the paper, what means have we for determining the pathology of the disease? Knowledge may be obtained from three sources: 1. Post-mortem examinations; 2. Exploration of the urethra during life; 3. Effects of remedies. Regarding post-mortem evidence, the views of Sir Astley Cooper, Rokitansky, Sir Henry Thompson and others were quoted, and the conclusion arrived at that the essential cause of gleet is a catarrhal inflammation of the urethral mucous membrane and its follicles; that stricturral narrowings are frequent; that when the gleet has lasted for a long time it sometimes happens that no pathological alterations can be seen.

It is interesting to notice that the lacunæ are quite commonly affected, and that the two portions of the urethra especially prone to chronic inflammation are the fossa navicularis and the bulb.

With regard to the evidence obtained by exploration during life, it was remarked that the endoscope had failed to fulfil the predictions of its inventor, yet was an instrument of value in determining whether circumscribed spots of inflammation exist along the course of the urethra. These patches have been found with greatest frequency in the bulbous portion of the urethra, and much stress has been placed upon them as a cause of gleet. They are, however, not to be regarded as the sole cause; and are absent in many of the milder cases. Exploration of the urethra by means of sounds should never be neglected in obstinate cases of gleet. But in using them, the fact must be borne in mind that the inflamed patches in the urethra are not always sensitive, and also that at certain parts of the canal a natural sensitiveness will be found. In certain cases the bulbous sounds are valuable aids in examination.

With reference to studying the pathology of gleet by observing the effect of remedies, it was remarked that certain cases are cured by the application of stimulating ointments to the fossa navicularis, perhaps in others as far back as the bulb, and that the frequent success attending topical applications points to a disease of a catarrhal character. In certain rare cases cure is spontaneous. The conclusions were embraced under four heads:

1. Gleet depends upon a chronic inflammation of the urethral mucous membrane, either diffused over a greater part, or limited to spots, chiefly to the fossa navicularis and bulb.

2. Gleet depends upon inflammation of the lacunæ opening into the urethra.

3. Gleet depends upon stricture of the urethra.

4. Vegetations along the course of the urethra, inflammation of Cowper's glands, the prostate gland or the seminal vesicles, etc., are but rarely the causes of gleet.

Dr. Sands then proceeded to the examination of certain views respecting the pathology of gleet, which have for their able advocate his colleague, Dr. Otis. These views assumes that gleet invariably depends upon organic stricture, especially strictures of wide calibre, and that the division of these strictures by internal urethrotomy offers a safe method for effecting a cure.

Dr. Sands denied that the healthy urethra has a uniform calibre, which can be ascertained and measured with precision. It is necessary, also, to recognize what is meant by the term calibre of the urethra. The term calibre is ordinarily employed to indicate the size of a tube. But anatomists have long recognized the fact that the urethra is not a tube, except when distended. This is true of both the living and dead subject, as proven by amputations and post-mortem examinations. Being a canal only when distended, and having elastic walls, the calibre of the urethra will vary within certain limits, depending upon the elasticity of the walls and the amount of force used in separating them.

The normal calibre of the urethra is obtained when the latter is moderately distended by urine during micturition, and, although this cannot be estimated with accuracy, there is reason to believe that it is not large. Reference was then made to the various methods which have been employed for determining the calibre of the urethra upon the dead subject. Reybard found the greatest diameter to be 18½ mm. Several casts of the urethra were exhibited, which had been prepared by injecting the canal with wax. One cast was made by using only a moderate amount of distending force, and consequently was smaller than the other three, which were made by using such distending force as could be employed without producing rupture. Although it cannot be proved that the distending force in every instance was the same in amount, but assuming that it was nearly so, it is ascertained by this means that the dimensions of the male urethra, when dilated, vary in different individuals. The results obtained in these cases agreed with those of Reybard, and the figures showed that there is want of uniformity of calibre in different parts of the same urethra. This is an important fact, although not new. The figures showed that the urethra has alternating contractions and dilatations throughout its entire length, but this is tacitly denied when we admit that the calibre of the urethra is indicated by the calibre of the bulb.

Dr. Otis alone denies the existence of a normal narrowing of the meatus externus, and regards the presence of a narrow meatus as abnormal. Dr. Otis does not state, however, that he has ever demonstrated

this himself, but quotes Henle for his authority. Dr. Sands held, however, that Dr. Otis had misquoted Henle, and mistaken the exception for the rule.

To meet the objection that these observations have been made upon the dead and not upon the living subject, Dr. Sands has studied the subject with the same care upon the living subject, and has found the urethrometer designed by Dr. Otis a valuable instrument in conducting this part of the examination. But he has not been able to obtain the same results which have been recorded for the instrument. He has examined the urethræ of twenty healthy adults, and, with a single exception, expanded the urethrometer in the bulb of the urethra to its fullest extent, 45, without causing decided pain or inconvenience. In some of these cases he was unable to bring the instrument forward more than an inch before meeting with resistance. From this it was inferred that the bulb in the living subject is generally capable of greater dilatation than can be effected by the urethrometer at any other portion of the canal. Thus proceeding, Dr. Sands has satisfied himself that there are variations in different portions of the urethra corresponding to the variations obtained by injections upon the dead body.

The assumption of an invariable calibre for any urethra is unwarrantable, and liable to lead to grave errors in practice. Dr. Sands is convinced that a healthy urethra, explored by large bulbous sounds, will grasp the instrument tightly at certain points, thus giving the deceptive feel as though stricture is present. This may arise from a deviation of the sound from the axis of the canal; from spasmodic action of the fibres surrounding the mucous membrane in front of the instrument; or from slight inequalities not constituting stricture. He would not have it supposed that he did not approve of the treatment of stricture by means of internal urethrotomy, but believed it to be applicable chiefly to close strictures, and as an auxiliary to dilatation. He is a firm believer in gradual dilatation, as by far the best method of treating the majority of urethral strictures. Finally, the use of sounds exceeding 25 mm. is very rarely necessary either for diagnosis or treatment of stricture of the urethra. Because the canal can be distended to a much larger size, it does not prove that it should be so dilated. The practice of slitting up the meatus is irrational. A sort of artificial hypospadias is produced, and except in special cases it should be left as it has been made by nature.

The paper read by Dr. Sands being before the Society for discussion,

Dr. F. N. Otis remarked that it was with pleasure that he appeared to discuss certain questions which had been brought forward by the President. For their were certain points upon which there was no disagreement between himself and Dr. Sands, and there were certain other points upon which they were very greatly at variance. Reference was then made to the manner of preparing specimens to aid us in the study of urethral conditions, and Sir Henry Thompson was cited as authority for the statement that all methods of examination upon post-mortem specimens are utterly valueless, as far as they furnish any aid in appreciating the condition of the urethra present during life. Dr. Otis then referred to the examination of 100 cases in the living subject, made within the last month by means of the urethrometer, and in the presence of Drs. George A. Peters, Stephen Smith, Bull, Bangs, and others. In these examinations it was shown that the bulbous portion of the urethra is the largest, and that through the anterior portion of the penis the instrument passed smoothly along to the meatus through a canal of practically a uniform size.

Now this was the invariable history and condition of every case examined. It was proved during these examinations that the urethra in every case was an individual part of the man, as much as the foot or hand, and that there could be no positive standard in estimating the calibre of the human male urethra.

Again it was demonstrated that there was a constant relation between the size of the penis and the urethra with which it was associated. By the term constant is simply meant a sufficiently trustworthy and exact guide to the urethral calibre for surgeons unable to avail themselves of the use of the urethrometer. Out of twelve consecutive cases, the proportionate relation was found to vary not more than 2 mm. in any given case. These examinations were made upon men who claimed never to have had venereal disease. The Doctor stated that in seventy-one out of the ninety-five cases, the relative proportion was within 2 mm. When the difficulties attending and surrounding an examination are taken into consideration, any plan of measurement which can show such results is worthy of consideration, and must be acknowledged to be of the greatest possible value if a more accurate method of examination is not at hand.

Dr. Otis did not regard the size of the external meatus as a guide to the size of the urethral canal, as stated by Dr. Sands; because the meatus is found of such variable size, that it is impossible to determine where we shall stop and say that we have a normal condition. A man may have a very small meatus, and yet never suffer any inconvenience as long as it remains unaffected by disease. It deviates from any assumed normal type, but it is a deviation, and is not of necessity abnormal. But if such a meatus becomes involved in inflammatory trouble it may give rise to serious consequences, not only with regard to the existing disease, but with regard to subsequent reflex disturbances. A contracted meatus is the almost invariable associate of gleet, and when the contraction is removed the gleet usually gets well quickly, while a meatus corresponding with the size of the urethra behind it, gave assurance that gleet would not follow in an acute urethritis.

Dr. Otis maintained that Henle's illustration of the peculiarity of the urethral orifice was repeated in his book in three separate and distinct places; that he had put forth his views not to show that the meatus indicates the size of the canal, but, on the contrary, to show an entirely different part of the construction of the organ; and that although in the text of his book he has made the statement that the meatus is the smallest part of the canal, thus confirming the idea which has been handed down from one generation to another from the earliest times, yet his transcripts from nature give a distinct denial to his claim, and confirms Dr. Otis's statement with regard to the correspondence of the meatus with the fossa navicularis, as he had previously claimed that Henle's illustrations proved. Reference was then made to the variation in size of the external meatus in the 100 cases examined, and they were found to measure in mm., 12, 15, 16, 17, 18, 20, 25, 26, 27, 34, 37, etc.; and the Doctor regarded it as impossible to pick out of these what should be called a normal standard. Several individuals were then brought forward, in which the size of the meatus corresponded to the size of the fossa navicularis, and at the same time showing the constant relation before claimed between the size of the penis and the urethra with which it was associated.

Dr. Otis wished it to be distinctly understood that

he did not regard the size of the bulb as the size of the urethral canal anterior to it. He had always recognized it as the largest part; also that there is a narrowing, between two and three inches from the bulb, of two or more millimetres, but that the *spongy* portion and fossa navicularis he had found practically of a uniform size where there is no disease, and that is the part which he always measures to estimate the normal calibre of the canal. He has also come to regard the little ridges which are encountered a short distance in front of the bulb in a healthy urethra, which feel very much like strictures, as folds of mucous membrane which are straightened out during erection, and very likely during micturition and ejaculation. This conclusion was arrived at from a case in which erection took place during the examination, and which was subsequently examined in the flaccid state.

Dr. Otis made the statement that the frequency of strictures at this point might be explained by the liability of the retention of solid constituents of the urine, during some urinary disturbance, in these folds, which finally result in their thickening and consequent contraction.

He also alluded to the use of the urethrometer as a delicate surgical operation, requiring skill and experience in order to obtain uniform results; and stated that in the 100 cases the sensation of fulness was experienced by the person under examination before the instrument indicated a circumference at that point of 40 mm. With regard to Reybard's experiments, they were made upon the cadaver, and the distending force was repeatedly carried up to the point of rupturing the mucous membrane; and Reybard himself states that after rupturing the mucous membrane the tissues of the corpus spongiosum are much more distensible.

Dr. Otis doubted whether any advantage was to be gained by a distention of the urethra by means of the urethrometer above a mere sensation of fulness. His object has not been to make urethræ larger than nature has intended; it is simply to appreciate them in their variations, and to appreciate the obstructions to which they are subject.

The Doctor then alluded to serious difficulties which might depend upon a stricture which will admit 28 or even 30 of the French scale, such as gleet, abscesses, from follicular inflammation, reflex disturbances, etc. Swelled testicle and inflammation of the bladder may depend upon strictures through which an instrument of 24 French scale can be passed with complete ease, and without such instrument conveying the slightest idea of an abnormal condition of the canal; thus squarely taking issue with the statement made by Dr. Sands, that an instrument 25 mm. in circumference is sufficient for diagnosis and treatment of urethral difficulties.—The hour for adjournment having arrived, further discussion of the subject was postponed to the next stated meeting of the society.

Physiology and Pathology of the Brain.—Dr. Eugene Dupuy, of this city, well known for his researches into the physiology and pathology of the brain, and a late assistant to Dr. Brown-Séquard at the Paris Faculty of Medicine, lectured, on January 24th, in the College of Physicians and Surgeons of Philadelphia, on some points of cerebral pathology. He very satisfactorily demonstrated, by analysis of cases and by interesting experiments, that the theories which have been prevalent since the works of Hetzig and Ferrier have been published, are not tenable, viz., that localization of functional centres in the brain is impossible.

Correspondence.

STATE EXAMINATIONS.

To the Editor of The Medical Record.

Sir:—Allow me to make a few comments upon your recent editorial on State Examinations.

In the first place, if we are to have State Examining Boards, the State, which will be largely benefited thereby, should have some interest in the matter. The object, as I understand it, is not merely to purge the medical profession of ignoramuses, but to protect the public against pretenders in any and every system of medicine. To this end the law should provide for the examination of regular and irregular practitioners. In order to prevent favoritism, the appointment of examiners should be in the hands of the Supreme Court and the State Medical Society of each State, *but not in the colleges*. The latter will always be sufficiently represented by their members in the State Society. An *auxiliary* board, consisting of one examiner on Practice and one on the Materia Medica of each irregular school, might be so appointed that practitioners of any system of medicine could be examined by the board. The colleges could confer their degrees as usual when authorized by a mandamus from the State Board, but I can see no advantage to be derived from changing the wording of diplomas. As to the number of examiners, seven would seem to be unnecessary; three to five are found sufficient for the examining boards of the army and navy, before both of which the ordeal would probably be as severe as that of any State board.

A *per diem* compensation might be open to the suspicion that the time of examination could be unnecessarily prolonged, but a fair remuneration—not less than $5,000 a year—may be provided, in the following manner: Let each matriculant pay into the State Treasury the usual graduation fee of $30 (to be returned in case the student fails to pass), and if the amount thus collected be insufficient for the stipends of the examiners, let the State supply the deficit. This plan would give an *independent, disinterested* examining board, free from all connection with the schools, and removed from all suspicion of favoritism and unfairness by its peculiar mode of appointment, and the fact that it represented all the schools or systems of medicine licensed by the State. It does no violence to the present college system of examinations (as at Harvard, for example), nor interferes with their ancient right to confer degrees,—it leaves *teaching* to the schools, and only requires the final examination to be made by the State Board, whose mandamus should be issued for the degree.

CHANGES IN THE PUBLIC SERVICE.

ARMY.

Official List of Changes of Stations and Duties of Officers of the Medical Department United States Army, from Jan. 23d to Jan. 29th, 1876.

McCormick, C., Surgeon.—Relieved from duty as Medical Director Dep't of California. S. O. 15, A. G. O., Jan. 21, 1876.

Keenly, C. C., Surgeon. To report to the Cond'g

Gen'l Dep't of California, for assignment to duty as Medical Director of that Dep't. S. O. 15, c. s., A. G. O.

Williams, J. W., Assistant Surgeon.—Leave of absence still further extended one month. S. O. 15, c. s., A. G. O.

Merrill, J. C., Assistant Surgeon.—Assigned to duty at Fort Brown, Texas. S. O. 9, Dep't of Texas, Jan. 17, 1876.

Hall, William B., Assistant Surgeon.—Assigned to duty at Fort Wrangel, Alaska Ty. S. O. 6, Dep't of the Columbia, Jan. 11, 1876.

Medical Items and News.

Quarantine.—The Assembly Committee appointed last winter to investigate the management of the Quarantine, Immigration, and Health Officer's Departments have presented a lengthy report, in the course of which they recommend the abolishment of the Board of Quarantine Commissioners:

The unwieldy board referred to has not for at least three years been called together, so that practically the Health Officer has had complete control over the important question of expenditures for salaries. The power of auditing bills contracted by the Health Officer might as well be exercised by the Comptroller. As to the custody of the property of the State, we submit that the Health Officer could very easily take charge of, and act as the custodian of, the property of the State, without any expense to the State. Therefore, we are of opinion that the office of Quarantine Commissioners should be abolished; that the powers now vested in the Commissioners be devolved upon the Health Officer; that a Board of Appeals, consisting, for the time being, of the Presidents of the Chamber of Commerce, of the Shipowners' Association, and the Board of Health of the City of New York, be constituted to serve, without compensation, for the purpose of deciding appeals from the decisions of the Health Officer; that the Health Officer pay the salaries of all employés in quarantine out of the fees collected by him; that all bills for repairs be contracted by him only, with the assent of the Comptroller, and paid by the Comptroller out of funds appropriated for repairs; that hereafter no appropriation be made for the maintenance of quarantine, except for necessary repairs; that the money earned by the State's boats in quarantine for the transportation of passengers and mails, and that derived from the care of the sick on Dix's Island, be accounted for and paid by the Health Officer to the State.

Aix-les-Bains.—Sir Dominic Corrigan, Bart., M.D., contributes some very interesting observations on the above in the December number of the *Dublin Journal of Medical Science.*

Material for Dissection.—Charles Scheffler has contracted to bury dead Chicago paupers for $1.40 each, and says that he means to sell the bodies for dissection. He argues that there is no law to prevent the business; that the burial, after the doctors are through with the corpses, will fulfil the contract, and that the plan will save money for the city, inasmuch as in no other way could a contractor do the work at the price.

The late Dr. Anstie.—In the London *Practitioner* for January, 1876, appears a memoir of the late Dr. Francis E. Anstie, by Thomas Buzzard, M.D. In the course of the admirably exhaustive history of the life and services of the lamented deceased, his biographer says:

"Some of the experiments which he performed were attended with considerable personal risk. On one occasion he fastened to his face an inhaler, containing an ounce of ether, placed his watch before him, took a pencil in hand, and began to make a mark upon a piece of paper on the lapse of every fifteen seconds. He soon lost consciousness, and when he could again distinguish his watch he found that thirty-five minutes had elapsed, and that he had made but two marks on the paper. He was alone during this experiment. Another time he took a grain and a half of very good extract of belladonna on going to bed, and woke in a state of delirium."

The Rank and Pay of Army Surgeons.—The bill of Senator Logan, now before the Committee on Military Affairs, provides that the number of assistant surgeons now allowed by law shall be reduced to 125; that the office of medical storekeeper is abolished; that from and after the passage of this act, in addition to the grades now allowed by law, there shall be four surgeons with the rank, pay, and emoluments of colonels; eight surgeons with the rank, pay and emoluments of lieutenant-colonels, to be promoted by seniority from the medical officers of the army.

Ulcerated Nipples.—M. Legroux (*Annales de Gynécologie*, Nov., 1875) advises the following treatment: Spread with a camel-hair brush a layer of elastic collodion around the nipple, in a radius of an inch or more; a piece of gold-beater's skin should then be placed over the nipple and collodion, taking care to make a few holes with a pin over the part of the gold-beater's skin which covers the nipple, so as to allow the milk to ooze through. No collodion should be spread on the nipple itself, as more pain might thereby be occasioned. By the rapid evaporation of the ether the collodion dries up and the gold-beater's skin adheres. The nipple is thus more or less pressed down by the latter, which in drying becomes tense. When the child is to be nursed, the end of the nipple should be wetted with a little water. The covering of gold-beater's skin becomes soft and supple, allows the nipple to swell, and protects the ulcers and fissures from the pain of suction. The mother or nurse thus suffers no pain, and the ulcers heal in a few days.

Postural Treatment of Palpitation.—A correspondent of the *Union Médicale* calls attention to the fact that palpitations, when not depending on organic disease, may be almost immediately arrested by bending the head downward, and allowing the arms to hang pendant. The effect is still more rapidly produced by holding the breath for a few seconds while the body is in this bent position.

Anti-Vaccination.—Dr. H. F. Germann, Prof. of Medicine, University of Leipzig, has just published a ponderous volume of one thousand pages on the subject of compulsory vaccination. Among other things Prof. G. claims that the scientific side of the vaccination question has not yet been so fully investigated as to justify any compulsion.

DIPHTHERIA.

CONDENSED FROM LECTURES DELIVERED IN JEFFERSON MEDICAL COLLEGE, ON MAY 13TH, 17TH, 20TH, AND 24TH, 1875.

By J. SOLIS COHEN, M.D.,

LECTURER ON LARYNGOSCOPY, AND DISEASES OF THE THROAT AND CHEST.

PART II.

PROGNOSIS.

THE prognosis is usually grave in diphtheria. Many cases progress to a favorable termination, but such a happy result cannot be positively predicated in any given instance, for those which are mildest at the outset may yet terminate fatally. The character of the epidemic, the hygienic conditions by which the patient is surrounded, and the opportunity that may exist for improving those hygienic conditions, all exert more or less influence on the general prognosis. We should hope for the best, and be prepared for the worst, in every instance; bearing in mind that no case, however trivial it may appear, is absolutely unimportant. Cases mild at the outset, may become severe at a later period; and relapses may occur even after the first subsidence of the alarming symptoms. The age of the patient is to be taken into consideration. In the absence of any other prominent indication, we find that the case is generally more unfavorable the younger the patient.

The general state of the constitution is of great importance. Previous general good health renders the prognosis favorable; while patients debilitated from any cause whatever are less likely to recover. Complications with other diseases, as measles, scarlatina, or pneumonia, render the prognosis unfavorable.

The deposit itself sometimes furnishes indications of the severity of the case; but by no means constantly. Simple tonsillar or pharyngeal (oro-pharyngeal) exudation alone is less grave than when complicated with naso-pharyngeal, nasal, or laryngeal exudation. When the tonsils are sheathed, as it were, in an envelope * of exudation, it is sometimes indicative of a condition in which laryngeal exudation is likely to occur; and the prognosis is therefore less favorable. Mild cases, however, in which there is but little deposit, may prove fatal by blood-poisoning, or by collapse before the local manifestation has become fully developed. Septic cases (so-called), and cases actually gangrenous, are exceedingly grave; the latter not only from the ulcerative processes that takes place, but from increased element of poisoning carried into the system by each inspiration over the fetid detritus in the throat.

Nasal diphtheria is of such grave augury that some observers consider it of fatal significance, though without sufficient reason therefor. In children at the breast it interferes seriously with nutrition. Epistaxis, therefore, and even moderate coryza, should attract prompt attention, as indicative of nasal complication.

In his letter to Drs. Blache and Guersant,† in referring to the terror felt by the former and by Trousseau at witnessing sudden loss of life after forty-eight hours' illness, Bretonneau asserts that he had recently acquired the conviction that the disease is developed in the nostrils and extends there without any warning and without any apparent symptom. He therefore urges that visible symptoms should not be waited for, but that, at the least sign of snuffling, at the slightest indication of coryza, swollen lymphatic glands should be felt for, not merely looked for, beyond the angle of the lower jaw, below the lobe of the ear, and thence down the sides of the neck. At the same time the upper lip will be found red below the nostril of the same side on which there is any glandular swelling, and unequally and proportionately upon both sides, if there is glandular swelling upon both sides.

Pain in the ear is mentioned by Bretonneau as an early symptom in one of his cases;* and by Dr. Beardsley, of Milford, Conn., as the first symptom in almost all the cases he saw in an endemic; occurring a day or two before any other complaint was made, and before any evidence of exudation could be detected in the throat.† I have observed the same fact in a few instances, and not only in diphtheria but in other inflammatory processes involving the tonsils, posterior palatine arches, and epiglottis. It is characteristic, perhaps, when present, but not pathognomonic.

Epistaxis, and so likewise hemorrhage from the throat, is sometimes indicative of blood change, as well as simply direct loss from destruction of tissue; while, when copious, this direct loss of blood itself is an additional complication of unfavorable omen. Irregular cutaneous rashes and eruptions, spots of ecchymosis and purpura, are likewise of unfavorable augury. Laryngeal diphtheria (diphtheritic croup), and with it, of course, diphtheria of the air-tubes from larynx to ultimate bronchi, is of the gravest significance, for it indicates the approach of mechanical impediment to respiration, a condition which can but add to dangers already existing. As far as the mechanical danger alone is concerned, the constitutional condition may be almost disregarded in the prognosis; the age of the patient, the relative calibre of the larynx, and other affected air-passages, and the tenacity of the morbid product, being points of much more importance.

During the first week of the disease, in cases not directly fatal from innervation or collapse, the danger is from the larynx, and if the larynx remain unaffected, the danger then lies in the exhaustion and deficiency of nerve force or energy; conditions which may ensue even in connection with but a trifling amount of inflammation and exudation in the throat.

The tumefaction of the submastoid, submaxillary, and cervical glands is regarded by some observers as proportionately indicative of the severity of the case, on insufficient grounds, however, according to the opinions of others.

The constitutional symptoms of the disease itself furnish indications for prognosis. High temperature may be regarded as unfavorable. A strong, full pulse is a favorable indication; a rapid and feeble pulse, on the other hand, is an unfavorable indication; while a vacillating and infrequent pulse is almost of fatal significance, unless dependent upon cardiac disease previously existing. Loss of appetite and unwillingness to take nourishment are unfavorable signs. Vomiting is an unfavorable indication, and diarrhœa still more so. The presence of albumen in the urine is regarded as an unfavorable sign, and when the albumen is very abundant, the case almost always terminates fatally. Dr. Wade,‡ to whom we are chiefly

* Bretonneau, op. cit., p. 21, note.
* Fifth Memoir, op. cit., p. 196.

* Op. cit., Fifth Memoir, p. 201.
* D. D. Slade: Diphtheria, Its Nature and Treatment. Philadelphia, 1861, p. 45.
‡ Observations on Diphtheria. London, 1859.

indebted for the observation of this symptom, found that indications of the impairment of the renal functions were constantly precursory of an unfavorable termination. When the albumen is abundant, there is sometimes uræmic intoxication, and delirium is almost always a fatal sign.

In cases terminating favorably, recovery usually takes place from the eighth to the fourteenth day, the symptoms gradually diminishing in severity and urgency with normal resumption of impaired function.

In cases terminating fatally, death usually occurs within a few days, sometimes not until the end of two weeks, and sometimes as late as the fifth week. The patient may succumb to asthenia, or exhaustion from the severity of the systemic disease, with or without invasion of the larynx. Death from asthenia may occur during the first week in delicate or debilitated subjects, in rare instances within thirty-six hours; but it is usually delayed until the course of the second week. The patient may die from sudden asphyxia, or from gradual apnœa, caused by the local impediment or obstacle to respiration. Asphyxia may be produced by the flapping of free or partly free exudation in the trachea, or in the larynx, which, while it permits inspiration, effectually prevents expiration by its valve-like action. The patient may die from the innervation following the disease, even after the establishment of convalescence, or even after apparent recovery. Bretonneau has recorded cases,* and so have others after him, in which, though the symptoms were mild, life was often lost, and in which the post-mortem evidences (even after tracheotomy) were insufficient to account for the death. Bretonneau saw no case survive the sixth day of laryngeal symptoms, without tracheotomy. Jenner † has twice seen death within twelve hours from the time the laryngeal symptoms were first noticed, and had never known it delayed more than five days after positive indications of the existence of the deposit in the larynx.

If symptoms of laryngeal implication have not become manifested within the first week, the danger from this cause, though by no means averted, diminishes with the relative prolongation of the attack.

A point to which attention is called by Prof. Flint,‡ who had seen two cases terminate in this way unexpectedly, is a liability to sudden, fatal syncope; even in comparatively mild cases, or during convalescence; and generally due to some unusual exertion, as getting out of bed. Dr. J. F. Meigs, among others, has reported§ cases in which sudden or unexpected death was due to the formation of clots in the right cavities of the heart. Similar instances are not unknown to other observers likewise.

The prognosis in diphtheria, then, should always be guarded.

THE APPARENT IDENTITY OF DIPHTHERIA WITH CROUP.

The majority of practitioners, at the present day, believe in the identity of croup and diphtheria: but a very respectable and equally intelligent minority are unable to support this opinion. A consideration of the main points urged upon both sides of this interesting question cannot fail to be instructive.

A lively correspondence on the subject has occupied no inconsiderable portion of the columns of the London *Lancet*, and of the *British Medical Journal*, during the present year; and has elicited special attention, from the fact, among other things, that a prominent London teacher, Sir William Jenner, who contended for the non-identity of the two affections a few years since,* is now an advocate of the theory of identity, in which, by the way, he has the unqualified support of some of the ablest and most prominent authorities in Great Britain.

For the fair discussion of the subject, as definite ideas as possible should be conceived of the terms diphtheria and croup. The former term has been sufficiently dilated upon, and may be regarded as indicating positive deterioration of the blood, in addition to the local manifestations described. The latter term has unfortunately become applied to several conditions which bear no pathological analogy save in a single result, which may follow causes very different in their nature—inflammatory, septic, toxic, and mechanic—and this one manifestation is laryngeal stridor with mechanical impediment to respiration. Now, discarding, once for all, such varieties of suffocative affections as may be included under the terms "false" croup, "spasmodic" croup, "stridulous" laryngitis, "thymic" asthma, and the like, we are to ascertain whether there is an acute idiopathic inflammatory affection of the larynx, or larynx and parts contiguous, of an exudative or pseudomembranous type, propagable along the bronchial respiratory tract, and occasionally along the respirato-alimentary tract, non-contagious in its nature, unassociated with constitutional disturbance as an essential element in its phenomena, and in which the sole danger to life is mechanical obstruction to respiration from swelling, or from the presence or accumulation of the products of the exudation;—an affection the inherent tendency of which is to recovery, apart from the mechanical obstruction mentioned. Cases of this kind are not frequent, at the present day, I am willing to admit. Many practitioners practise a long while without encountering them; still they are by no means rare, and have been observed and recognized by many practitioners.† Gentlemen who have not encountered cases of the kind deny the existence of a true non-systemic croup, instead of simply stating that they have never seen the disease. These cases represent the true croup of those who believe in the disease independent of diphtheritic intoxication, and are classed as sporadic diphtheria by those who contend for identity. There is no doubt that many advocates of the existence of a true croup include undoubted cases of diphtheria in their category; while cases of supposed croup, on the other hand, are included in the categories of those of the contrary opinion. Hence much of the existing confusion as to what is a case of diphtheria, and what a case of croup. If we are willing to admit, as I think we safely can, that a patient with diphtheria may contract croup, and a patient with croup may contract diphtheria, this obscurity disappears in part. This is not mere begging the question. Typical cases differ as much as ever, but cases of coexisting disease partake of the nature of the two extremes, and the anatomical phenomena of both gradually merge into each other, while the clinical manifestations become blended. The existence of the one does not afford immunity, at the time or for the future, against the contraction of the other; and they

* Op. cit., p. 47.
† Op. cit., pp. 36, 37.

§ Am. Jour. Med. Sciences. April, 1864, p. 395.

* Diphtheria: Its Symptoms and Treatment. London, 1861.
† I may mention, that at the close of the lecture in which the above remarks were made, a well-known physician informed me that he had followed me from my office to get me to see a case in consultation, which he had believed to be diphtheria, but which he now thought, from the tenor of my remarks, might be what I considered as true croup. I accompanied the gentleman to his patient, and found a case of croup, similar to the typical hypothetical case in the text. The case terminated favorably.

may appear together, or in rapid sequence, or they may follow at long intervals.

If the term croup is applicable to any inflammatory affection of the larynx, trachea, and parts contiguous, which is accompanied by the development of a product which when completed represents an adventitious membrane, then it appears to me that we have several varieties of croup:—

1. *Idiopathic or sthenic croup, true croup;* a purely inflammatory local affection, non-specific in its origin as far as we know, sporadic in its appearance, rarely implicating the tissues above the larynx, rarely occurring more than once in the same individual, confined almost exclusively to childhood, non-contagious, and unattended with any essential systemic complication; death occurring mechanically from asphyxia, or from slow apnœa, or from asthenia consequent on the impairment of vital force produced by prolonged impediment to respiration.

2. *Systemic croup, or the croup of diphtheria;* a systemic disease, specific in its origin to the best of our knowledge, accompanied and in part preceded by pseudomembranous manifestations in the pharynx, nares, and portions of the alimentary tract, often followed by certain characteristic disturbances in the nervous, circulatory, and glandular systems, frequently occurring more than once in the same individual, endemic or epidemic in its appearance although sometimes sporadic, contagious in its nature, and attacking people of all ages, though more frequent in children; the tendency being to death by asthenia, though it is likewise liable to prove fatal mechanically from obstruction of the air-passages.

3. *Deuteropathic croup;* such as becomes developed in connection with certain of the exanthemata, typhoid fever, and the latter stages of phthisis and other diseases of malnutrition, in which it is often associated with similar deposits in other portions of the body; therefore bearing a closer physical resemblance to the local manifestations of diphtheria: and

4. *Traumatic croup;* such as follows the local action of steam, acids, vesicants and mechanical injuries, the membrane, as remarked by Bretonneau,* remaining circumscribed about the injured parts.

Certainly a special diathesis or a special infection is not necessary for the mere production of false membrane. In all these instances, the membrane is diphtheritic in the sense of being adventitious, but, as we know, adventitious membranes may become developed under still other conditions, as from the local influence of irritant gases, local injuries, and the like. To add one more to the examples that have been reported from time to time, I have in my possession a number of fragments of membranes coughed up during two years, following a tracheotomy which I had performed for the extraction of a foreign body (beef-bone) which had remained in the trachea for more than two years; and the patient informed me that she had coughed up "such fragments of flesh" from time to time before the operation. There were no general symptoms indicative of the process of membranous formation or exfoliation.

The problem offered for solution is whether the first form is an independent disease, or simply a sporadic variety of diphtheria—the second form. That instances of the first form were known to the ancients under different appellations there is abundant proof.†

It is also evident that this form of disease is not identical with the so-called *gangrenous angina* which Bretonneau first discriminated as a special affection, and to which he gave the name *diphthérite*.

Bretonneau contended for the identity of croup and diphtheria, and believed* that "Francis Home persuaded himself that he had just met with an affection which had hitherto escaped the attention of his predecessors," and that his new name "so fascinated all persons that it prevented them from recognizing a disease observed from the most remote antiquity." At the same time Bretonneau states distinctly that "no inflammation with exudation is *diphthérite* when it does not spread by contagion;" the membranous exudation being considered by him as the poison itself.

The development of diphtheritic patches upon abraded cutaneous integument is universally known, whether due to a local deposit or to an exudation from the tissues. It is not improbable, at least in many instances, that the diphtheritic patches in the throat are first developed on abraded surfaces. There is usually some history of catarrh preceding the development of diphtheria. Now, this catarrhal inflammation of the laryngo-tracheal mucous membrane may produce an elevation or separation of the epithelium, and thus represent the condition of abraded integument. It is difficult, and sometimes impossible, to recognize slight losses of epithelium with the unaided eye, in the usual method of examining the throat, and the pharynx and parts contiguous to it may be in this abraded condition previous to the attack. Granting this, the two processes in the skin and in the mucous membranes are analogous.

Attempts at discrimination in the nature of the exudation have failed, although characteristic differences, chemical, microscopical, and physiological, are still contended for by some pathologists. The discriminating condition pointed out by Virchow some years ago, and so extensively supported, that the pseudomembrane of diphtheria is adherent to the mucous membrane, or infiltrated into it, while that of croup simply lies upon the mucous membrane, is now acknowledged by him† as lost in particular cases: true croup of the larynx and trachea invading the pharynx and often actually coexisting with diphtheria, and not presenting as a free exudation until we reach the deeper bronchi or the pulmonary vesicles.

We cannot establish any essential difference on anatomical grounds, the pathological products of the two affections being identical as far as our means of examining them are to be relied upon.

There is no absolutely characteristic manifestations in the location of the pathological product, nor in the condition of the mucous membrane beneath it; even destruction of tissue being sometimes encountered in croup as well as in diphtheria.

When we investigate the clinical features and manifestations of the two diseases, we can, I think, recognize a difference as tabulated below:

CROUP.	DIPHTHERIA.
Non-specific in origin.	Specific in origin.
Never contagious.	Often contagious.
Not inoculable.	Inoculable.
Not of adynamic type.	Of adynamic type.
Usually sporadic.	Usually endemic or epidemic.
Rarely attacks adults.	Often attacks adults.

* In the case of the prolonged sojourn of foreign bodies a permanent adventitious membrane envelops them and renders their retention harmless.

† See especially, observations tending to ascertain whether the ancients were acquainted with the disease known to us familiarly by the name of croup, by John Redman Coxe, M.D., Prof. of Materia Medica and Pharmacy in the University of Pennsylvania.—*Am. Journ. Med. Sc.*, Nov. 1828, p. 56.

* Op. cit., p. 4.

† Pathologie und Therapie, I., p. 282.

CROUP.	DIPHTHERIA.
Always accompanied by exudation.	Sometimes unaccompanied by exudation.
Fatal only by physical obstruction to respiration, whether directly or indirectly.	Often fatal without any physical obstruction to respiration whatever.
No depression of heart.	Marked depression of heart.
Pulse often strong and hard.	Pulse never strong and hard, even though quick and full.
Respiration more accelerated in proportion to the pulse; ratio rarely if ever less than one to four.	Respiration not accelerated in proportion to the pulse; ratio usually less than one to four.
Albumen rarely in urine.	Albumen often in urine.
Not followed by paralysis.	Often followed by paralysis.
Would bear antiphlogistics.	Would not bear antiphlogistics.
Rarely attacks more than once.	Often attacks more than once.

In addition to this, it may be mentioned that diphtheria, unlike croup, has never been thought due to excessive plasticity of the blood.

With regard to contagion, it may further be remarked that I know of no recorded instance of undoubted croup (such a case as would not be classed as diphtheria by these contending for non-identity) which has been traceable to exposure to the contagion of a case of diphtheria (such a case as would be designated diphtheria by the partisans of both views). Evidence to the contrary ought to be accepted as conclusive. With regard to the pathological product, it may be admitted that no one doubts that diphtheria may exist and even terminate fatally, without the development of any membrane in the larynx or below it. No one doubts either that the disease, to constitute croup, necessitates the production of a pseudo-membrane or its representative in the larynx or trachea, or bronchi. In diphtheria, too, the membranous affection in the larynx is secondary; and, on the other hand, croup does not necessarily affect the pharynx. Diptheritic cases may be mistaken for croup, and thus the two be regarded as identical, from there being evidences of membranous exudation in the larynx, but none in the pharynx; the fact being, as often demonstrated necroscopically, that the membrane had occupied localities out of direct sight, such as the posterior surface of the palate, the lower portions of the œsophagus, upper portion of the pharynx, and the like. Laryngoscopic and rhinoscopic inspection, when practicable, would set such doubts at rest.

In the same way as we have enteritis and typho-malarial enteritis, pneumonia and typhoid pneumonia, erysipelas and malignant erysipelas, we may have croup and diphtheria; the disease being due to an ordinary cause in the one instance, and to a specific cause in the other; the analogy being in the organs or tissues affected, and the difference in the mode of origin and in the systemic complication.

Uninflammable Fabrics.—The London journals are much exercised over an accident in the Alexandra Theatre, Sheffield, by which a ballet girl was burned during the representation of a fairy scene. The *Lancet* maintains that the fabrics of these girls should be made uninflammable by immersion in a solution of neutral tungstate of sodium mixed with three per cent. of phosphate of sodium, and that such a precaution should be enforced by law.

URETHROPLASTIC OPERATIONS

TO REMEDY

HYPOSPADIAS, EPISPADIAS, AND ALSO INCURVATION OF THE PENIS.

By J. W. S. GOULEY, M.D.,

SURGEON TO BELLEVUE HOSPITAL.

Some years ago I directed my attention to certain plans of operation to remedy congenital malformations of the penis, which, for lack of proper material, I could not carry out until the case narrated below presented itself. I think that these processes can be adapted to the three principal varieties of hypospadias, and also to balanic epispadias; and they seem to me more promising than those heretofore employed.

Balanic hypospadias, which is very common, has generally been considered too trivial to merit much notice, except it be attended with constriction of the urethral orifice, which then constitutes one of the forms of congenital stricture, and demands internal lateral incisions.* But there are cases in which, even after free internal division, sufficient irritation still exists to cause sundry derangements of the nervous system, and to annoy the patient in various ways, and in these scarcely anything short of an operation will give relief.

In September, 1875, a gentleman requested an opinion from me regarding the propriety of his being operated upon for congenital balanic hypospadias. He had already been subjected to several operations, all of which had failed. One, he said, had consisted in denuding the edges of the gap or fissure, and bringing them together with wire sutures. But before this last attempt, an endeavor had been made to "dig a canal through the glans penis." The appearance of the deficiency was similar to that represented at A (Fig. 1), the malformation extending a little beyond the line of the base of the glans. At about half an inch from the end of the penis, the fissure was traversed by a cord-like isthmus of mucous membrane about an eighth of an inch in thickness. This was the result of the "digging" just referred to, and through the foramen which resulted, No. 8 sound only could be passed, while the urethral orifice at the proximal extremity of the gap admitted a No. 15 sound quite easily. There was also a slight degree of incurvation of the penis in its last inch. I told the patient that I had declined to operate in several cases similar to his, because I thought the malformation too slight to cause more than a very trifling inconvenience, and that for the same reason I would, in his case, advise against an operation. But as he gave me to understand that this affliction was preying greatly upon his mind, and as he became very urgent that I should undertake to remedy his trouble, I finally consented to do so; but deferred the performance of the operation for a few days in order to mature the plan that I had already conceived tor cases in which the defect is more extensive.

On September 9th, 1875, assisted by Dr. Z. E. Lewis, I executed the operation in the manner herein described, after having had the patient etherized. As nothing could be gained by preserving the isthmus A (Fig. 1), and as it was really in the way, I snipped it in the centre, and its cut ends retracted to either side so as to be almost out of sight. I then made a longitudinal incision, beginning at B, and extending to C, and another parallel with the first, and a quarter of an inch to the ontside, from D to E, and the two were united by short cuts from B to D, and from C to E.

* See Gouley on Diseases of the Urinary Organs, p. 107.

The teguments were dissected off from all the space bounded by these incisions. This process was repeated on the opposite side. The mucous membrane and skin in all the central space, half an inch in breadth, more or less, included between the incisions B B to C C, from A to K, and beyond, were preserved intact. The incisions B C, B C, were about one-twelfth of an inch distant from the edge of the

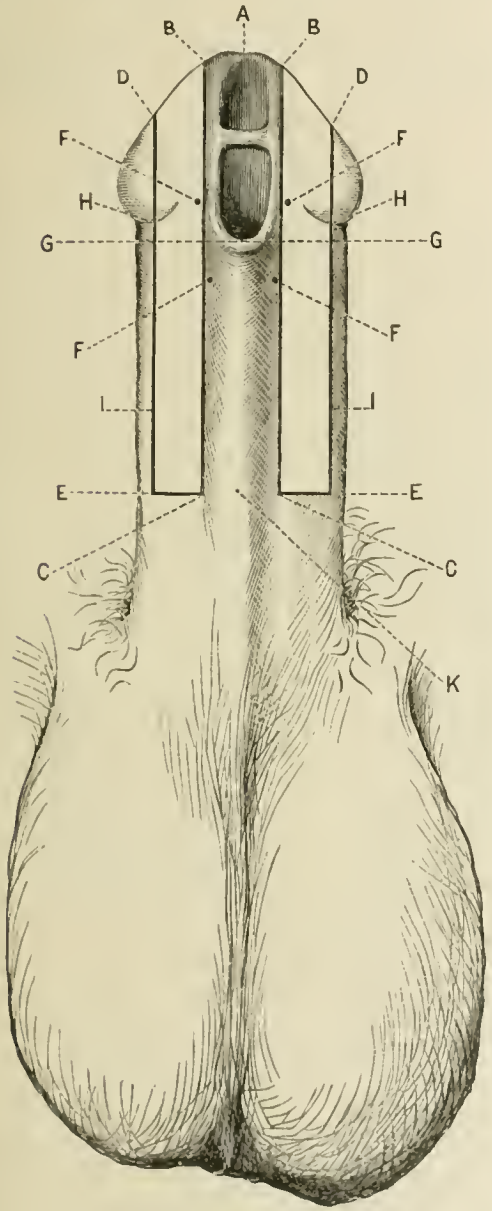

Fig. 1.

somewhat elliptical gap at its widest portion, and of course farther off above and below, being made quite straight and with a view solely to the necessary width of the new urethra. The next step consisted in gradually sliding the skin, so as to double it upon itself and bring the lateral denuded surfaces into apposition, to be so retained by a number of fine silken sutures in such a manner that C C would be united to B B. But to effect this I had to begin to stitch at F F, passing the suture from within outwards above, and from without inwards below, so that in folding the central skin which was to form the urethral floor, the angle or crease came at the point represented by the dotted line G G, as close as possible to the edge of the abnormal urethral orifice. Before tying the suture of one side, that of the opposite side was first passed, then the other threads were successively applied on either side, tied, and cut short, so that their free ends lay inside the newly formed urethra, until the last two, uniting C C to B B, were secured;—in all five on each side. Four additional sutures were passed on each side along the lines formed by the apposition of C E I to B D H. The stiching completed, the meatus became transverse instead of longitudinal, its inferior lip being the fold of skin from K, formed by the apposition of the points C C to B B, and its superior lip the edge of mucous membrane from B to B.

To prevent erections, ice-water dressing was used, and hyoscyamus and camphor given freely at night. The patient drew off his urine periodically with a No. 8 soft India-rubber catheter; each time, as directed, pinching closely the distal end of the instrument while withdrawing it. He followed so faithfully this latter injunction that not a drop of urine ever came in contact with the wound, which healed primarily. Some of the sutures were removed on the fourth day, and several others remained twelve days in the urethra, creating very little if any irritation, and were readily cut away.

Three weeks after the operation he indulged in the sexual act without any marked inconvenience, but thought that, during erection, the incurvation of the penis was somewhat increased, and determined to have this remedied by a second operation, which he underwent on October 16th, 1875. I made, on each side, through the integuments, an incision, beginning near the base of the glans—where the prepuce was quite loose, and resembled a pair of wings—and carried the cuts along the under-surface of the organ, upwards and inwards to the median line, a little beyond the proximal extremity of the newly formed urethra, where they were united, making a V-shaped wound. The central skin, which formed the floor of the new urethra, being thus liberated, was pulled forward as much as possible. The edges of the wing-like processes having been clipped, the skin was drawn back and stitched to the sides of the V in such a manner as to convert it into a Y. But as this produced a considerable degree of circumferential tension, I next made a longitudinal cut, an inch and a half long, only through the skin, on the dorsal aspect of the penis, and began to stitch it by bringing together its two extremities, and so converted it into a transverse wound, with the effect of completely relieving all tension, and at the same time of causing the organ to curve slightly backwards. The wounds healed primarily, except a small portion on the under surface which granulated. The patient was out in a week. His penis is now straight, and causes him no further anxiety or inconvenience.

A few weeks ago (January, 1876) I described my method of operating to Professor A. C. Post, who applied it to a case of balanic hypospadias, resulting from a phagedenic chancroid. The operation was entirely successful. The Doctor had proposed to open the urethra in perineo, in order to keep the urine away from the wound near the point of the penis, but finally concluded to adopt my simpler and safer plan of requiring the patient to pass all his urine by the aid of a

soft rubber catheter, introduced as often as his bladder required relief.

To avoid employing a major, as an auxiliary to a minor operation, is a surgical precept that should not be disregarded, and, in accordance with this doctrine, it would be as wrong to perform external perineal urethrotomy, with the sole object of preventing the flow of urine upon a wound made to remedy balanic hypospadias, as it would to first tie the brachial in order to control hæmorrhage from the digital arteries in amputation of a finger. These objections are, I think, in themselves sound and conclusive; but even if they were insufficient, there are other reasons why this measure should be condemned. The experience of past years has taught that the endeavor to turn the current of urine, at least for the first day or two, by making a perineal opening, is almost certain to fail. It is well known that during the first day after this

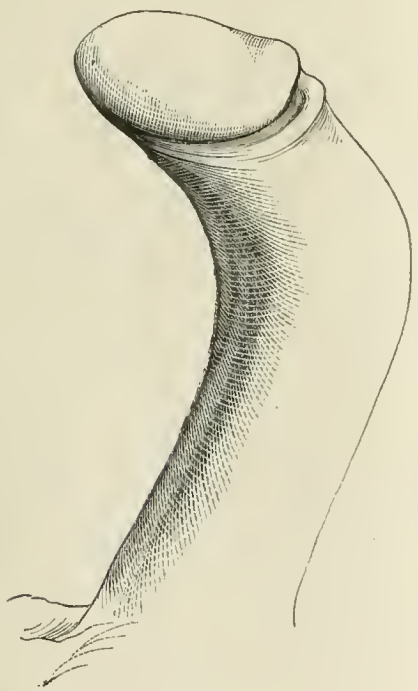

Fig. 2.

(Enlarged from Bouisson.)

operation the urine usually flows through the whole urethral canal, owing to contact of the swollen lips of the wound in the perinæum. But it has been said that this might be "obviated by a catheter passed into the bladder through the perineal wound, and retained in position." That a catheter so introduced and retained does not always prevent the escape of some urine through the whole length of the urethra, during the first twelve hours, has long since been proved by many excellent observers. Therefore, I venture to assert, and hope to maintain, that opening the urethra in perineo, as an adjuvant to this anaplasty, is worse than useless, since it constitutes not only a complication of some gravity, but a delusive procedure, calculated to defeat the very object which the operator may seek to attain, *i.e.*, to prevent the urine from contaminating the wound at the anterior extremity of the urethra, exactly as it would if it were voided spontaneously, or if it trickled beside a catheter passed through the meatus and retained in position.

In Dr. Post's case, where there is no incurvation of the penis, it is almost impossible to discover any traces of the surgeon's work. All that is observable is that the meatus is transverse, and that the prepuce, which has grown fast to the point of the penis, can be retracted only sufficiently to uncover the upper surface of the glans. If in this case there should be any tendency to accumulation of smegma, the prepuce could be slit on its dorsal aspect, or another operation could be done to construct a new prepuce capable of partially covering the glans, and of being completely retracted. The operation would be so simple that I shall take no space to describe it.

SCROTAL HYPOSPADIAS WITH INCURVATION.

When, in the scrotal variety of hypospadias, there is such incurvation of the penis as to impede sexual congress, an operation should be done to straighten the organ, and subsequently a new urethra might be constructed. It must be evident to all who have carefully examined cases of congenital hypospadias with incurvation that the abrupt bend in the penis (Fig. 2) is due entirely to the defective urethra, which checks erection, as in the "chordee" of acute urethritis. To remedy this deformity, the operation ordinarily performed consists in cutting across the bridle-like urethra, and then applying such dressings as will ensure a curve in the opposite direction until the completion of the healing process; generally, however, this is unsuccessful. Bouisson, of Montpellier, reports a case* of this kind, in which he resorted to division of the bridle three different times; and though he severed it completely down to the sheath of the penis, and was very careful in the after-treatment, he failed each time. The reason of his failure is that he made a transverse wound, and when cicatrization was completed, the parts resumed their former condition. In point of fact, a transverse wound will generally leave things in a much worse state than before. I was so deeply impressed with this fact, from reading Reybard's account of his experiments to illustrate the effect of different wounds of the urethra, that I determined to contrive an operation for splicing, and so lengthening the short and curved urethra in hypospadias, thereby avoiding a transverse cut. Early in 1866 I saw two cases of scrotal hypospadias with great incurvation of the penis, which I thought fit for the operation, but circumstances prevented its performance.

The splicing process above mentioned was to consist in making a sigmoid incision to involve the whole thickness of the urethral wall to the sheath of the corpora cavernosa penis, from L to M (Fig. 3), and two lateral cuts from the base of the glands N N to O O, a little beyond the orifice of the urethra P. The sigmoid incision was to be made an inch and a half long, as the urethra was to be lengthened by an inch. As soon as the parts would be liberated, the traction made upon the penis, in the endeavor to straighten it, would bring together obliquely the edges of the sigmoid incision near its points L and M, which would take the position represented at R (Fig. 4), where a couple of fine silken sutures would be applied; then the edges of the long lateral cuts S T, S T (Fig. 4) would be stitched to the edges of the central portion, during which time an assistant should hold firmly the glans in such a manner as to curve the penis backwards. The diagram (Fig. 4) is drawn on the same

* Bouisson, Tribut à la Chirurgie.

scale as Fig. 3, and is intended to represent one inch of gain.

Ice-water dressing should be applied in such a case, and the penis drawn back upon the hypogastrium, or it may be guyed by a double suture passed through the point of the glans, and then through the skin of the pudic region, and so retained for three or four days. This is all I then intended to do; but now, the first operation succeeding, I would go a step farther, and in about four weeks afterwards would under-

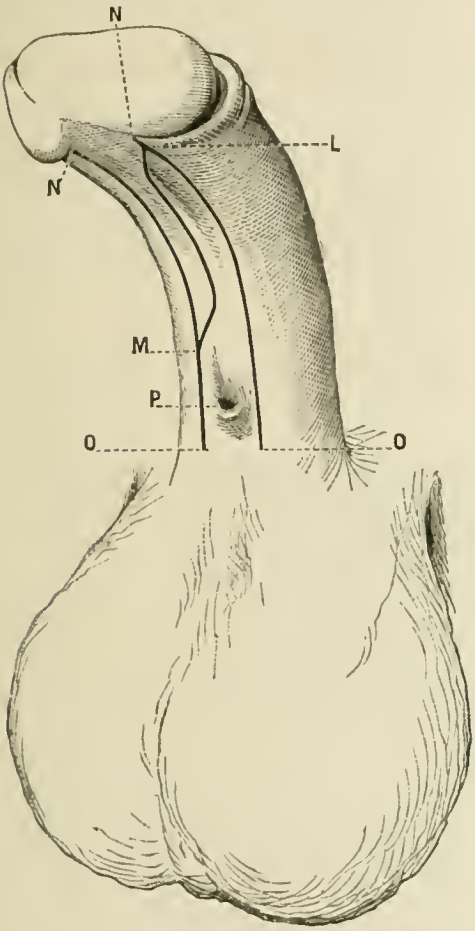

Fig. 3.

take to construct a canal from the orifice of the urethra P, in front of the scrotum, to the point of the penis, after the manner described for balanic hypospadias, but borrowing the tissues from the scrotum: that is, leaving intact a central quadrilateral portion of skin of sufficient dimensions, and making denudation on each side, and sliding and stitching, as in the balanic operation.

In perineal hypospadias, and in epispadias, the same principles can be applied, with such modifications as will be suggested by the particular condition of the parts in each case; always folding the skin forwards, and stitching as before described.

The method just detailed for lengthening mucous or cutaneous surfaces by splicing, can, I think, be adapted to anaplastics in various parts of the body, and also to operations for remedying certain deformities due to loss of substance from burns and other causes.

If, in the performance of the operations described above, particular attention be given to the following details, the chances of success will be greatly increased.

1. The vertical incisions B C, D E (Fig. 1), should be a little longer than the tissure to be closed. If the latter be an inch and a half long, the former

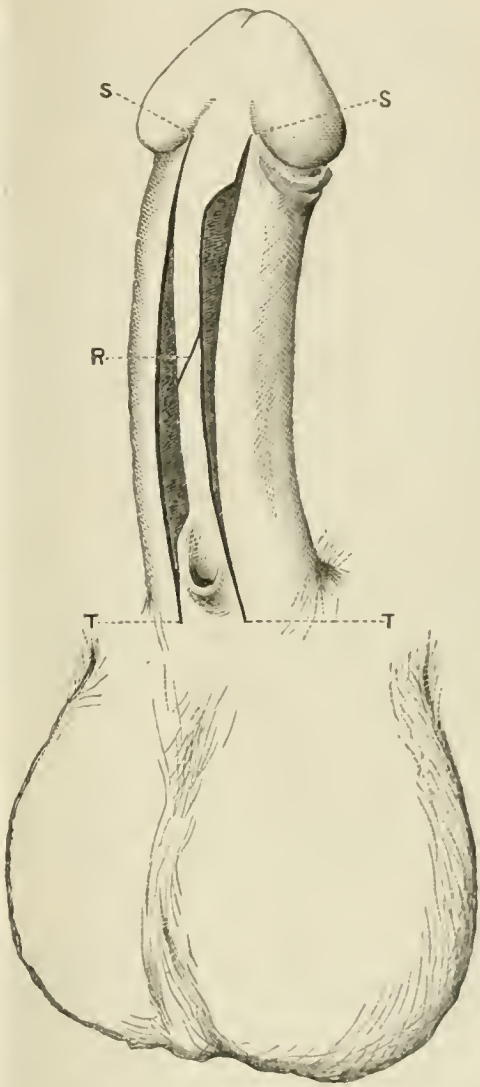

Fig. 4.

should extend a quarter of an inch farther back, to guard against any possibility of tension, and also to allow for subsequent retraction.

2. The denudation should extend a little more outwardly upon the glans, where the mucous membrane is less movable, than upon the body of the penis, where the skin is retractable by its own elasticity, owing to the underlying loose connective tissue.

3. Enough sound skin should be left in the centre, between the incisions B C, B C, from A to K (Fig. 1) to make a capacious urethral canal.

4. The mode of applying the sutures so that the knots may lie within the newly formed urethra is one of the most important features of the operation, and if the operator wishes to ensure apposition and rapid union of the parts, he should bestow no little care upon this step.

5. No catheter should be retained in the urethra, but the bladder should be emptied as often as required, by means of a soft India-rubber catheter not larger than No. 8 of the English scale. Great care, however, should be taken while withdrawing the instrument to pinch up its distal end, in order to prevent any urine from lingering in the canal or saturating the wound.

6. If the denudation be free enough, and apposition of the parts be effected, union, if not by the first, certainly by the second intention, may be confidently expected in the majority of instances.

7. In case of failure of the operation, the parts will probably be in no worse condition than before, and a second operation can soon be attempted.

8. In the operation for splicing the cord-like urethra (Fig. 3), and lengthen it, say by an inch, the sigmoid incision L M should be made about half an inch longer, to allow for retraction and also for the oblique position in which the ends of the flaps are placed (see R, Fig. 3). This incision should involve the entire thickness of the urethral wall, and expose the sheath of the penis, but care should be taken to avoid wounding the cavernous bodies. Any bands of connective tissue which might prevent the flaps from being slid in the right direction, should be divided, but the spongy body should be disturbed as little as possible from its bed.

9. The lateral longitudinal incisions S T, S T (Fig 3), should be made close to the edge of the urethra, and deep enough to expose the sheath of the penis; and in stitching them to the edges of the central portion traction should be made upon the penis, which should at the same time be curved backwards.

10. The second operation, to construct the new urethra, should not be attempted in less than four weeks.

311 Madison Avenue, New York, *February* 3, 1876.

ON A READY METHOD OF ADMINISTERING FLUIDS WHEN THE JAWS ARE FIRMLY CLOSED.

By F. A. BURRALL, M.D.,

NEW YORK.

A simple examination, which any one can easily make of his own buccal cavity, will show that posterior to the last molar teeth, when the jaws are closed, is an opening bounded by the molars, the body of the superior and the ramus of the inferior maxilla. If on either side the cheek is held well out from the jaw, a pocket or gutter is formed into which fluids may be poured, and they will pass into the mouth through the opening behind the molars, as well as through the interstices between the teeth. When in the mouth they tend to create a disposition to swallow, and by this method a considerable quantity of liquid may be promptly given.

I have used this plan for some time, and the simplicity of it makes me hesitate to present it in this article. At the same time I know it is new to some practitioners, nor have I seen it mentioned in any journal. It is one of those apparent trifles which are often very useful in practice.

Recently a patient whom I was attending during labor was seized with convulsions after the delivery of the head by forceps, and while the body, which was unusually large, was being extracted. Chloroform, which had been discontinued after the emergence of the head, was again administered, with the effect of controlling spasm. The unconsciousness of the patient had interfered with the administration of a dose of ergot, which should always, I think, precede the delivery of the placenta, and after the extraction of the body decided hemorrhage began.

As the patient partially revived, although her jaws were still firmly set, I poured the fluid extract of ergot mixed with water into the cavity formed by her retracted cheek and the liquid passing into the mouth was soon swallowed. The hemorrhage continued but a short time.

I have not found that liquids thus administered run into the larynx, nor do I think this is likely to occur if too much is not given at once. It is more probable that they would pass over the arched pavement of the tongue into the gutter beside the tongue and larynx.

It is not to be supposed that this method will always succeed, but it is worthy of a trial and can be tested promptly. Uses of it will at once suggest themselves to the physician.

Progress of Medical Science.

Non-inoculability of Phthisis.—In a paper read before the Académie de Médecine, M. Metzquer combated the well-known assertions of M. Villemin as to the inoculability of tubercle, and related experiments that gave contradictory results to those obtained by that observer. The latter is said to have killed his animals too soon, so that he was unable to determine from the evolution of the disease whether it was really tuberculosis or not. M. Metzquer, after producing exactly the same lesions, saw his animals recover after a longer or shorter interval, which he regarded as a proof that the lesions were not tuberculous. Moreover, lesions, to all appearances tuberculous, were found to be produced by inoculation of many other substances besides tubercle. M. Metzquer concluded, from 130 experiments, that the nodules developed by inoculation were not tubercular, because they were most frequently reabsorbed; because they could be produced by the inoculation of different substances, and, finally, because his experiments showed that the older the tuberculous material inoculated was, the greater was its activity; while, on the contrary, truly virulent substances succeed better when employed at a less advanced period of evolution.—*Journal de Médecine*, Dec., 1875.

Resin of Copaiba in Ascites.—Dr. Samuel Wilkes has tried this remedy for two years past, as a diuretic, and considers it of great value. The old objection to the use of copaiba is entirely done away with by using the simple resin after the nauseous oil is removed. In cardiac and hepatic dropsy its efficacy is undoubted, more especially in the former case. In a case mentioned, after digitalis, squill, and mercury had ceased to be effectual, the copaiba taken in doses of fifteen grains (made into pills), three times daily, removed all dropsical fluid in a few days. The excellent property of this drug is, that if it acts on the kidney at all, it acts at once. If the first or second dose does not display its diuretic effect, there is no use in persisting in it.—*British Medical Journal*, December 25, 1875.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

HOSPITAL CONSTRUCTION AND ORGANIZATION.*

V.

How to temper and how to ventilate the model hospital are themes to which our authors very naturally devote much consideration. In private dwellings these are complicated problems. In hospitals such as this they involve most critical interests, and call for the astute study of the physicist, the engineer, and the physician.

Dr. Billings (page 44) and Dr. Jones (page 120) very properly give as a starting-point the meteorology of Baltimore. The former thinks there is need of artificial heat only about three months (page 19), and remarks that the real difficulty in ventilation will occur in warm, still weather. All the others seem mainly to be providing for cold weather.

Dr. Billings gives preference to heating by hot water on the low-pressure system, since air heated thus to 150° F. is more agreeable than when heated to over 200°, as it must be by furnace or steam radiators. He admits, as an objection, that you cannot moderate heat or overcome cold so rapidly as by steam radiators. He raises the question, whether separate boilers (page 19) for each building are not desirable. We are glad also that Mr. Neirnsée (page 339) gives his approval of an entire isolation of the heating apparatus for each ward, and also (page 360), in case of two-storied wards, makes a separation for each ward. Expense is probably diminished, and one of the most important conditions of isolation secured. Dr. Morris says (page 183) the warming and ventilation of each ward should be entirely independent and isolated. Dr. Folsom (page 59) places main dependence on heating by low pressure steam apparatus and indirect radiation. He has one general boiler-house in a separate building and at one extreme of the block (page 63). Dr. Jones advocates hot water on the low-pressure system, either (page 121) by a central heating apparatus for each building, or so as to supply the entire hospital. He strongly insists that wards should be of different temperatures, to accord with the varied conditions of disease (page 122). This seems to us best secured by separate boilers. In another place he gives approbation to all that is said by Parkes, in his Manual of Hygiene (page 376), in advocacy of hot-water pipes and radiating grates. Dr. Smith (page 313) claims that in Baltimore no elaborate system of heating can be required. He therefore does not elaborate a plan, but says either the fire-place or its principle should be adopted, or the ward should be warmed through an air-chamber heated by coils of steam-pipe, the latter method being spoken of as economical. From his remarks as to "machinery, care, and supervision on the part of attendants," we suppose him to mean a separate apparatus for each ward. He gives prominence (p. 312) to a heating of the floors and walls of the building by heated air, which reaches them after being warmed by steam-pipes in the basement. The walls also are warmed by connecting the interspaces with the lower air-chamber. Between the roof and ceiling he has also space for admission of this warm air. These fire-places help to warm the wards, and registers are arranged for special needs. It is well to compare all this with what we have said as to structure itself, and not make of it too much of an artificial heating and airing apparatus, and so interfere with natural processes.

The fire-place would only be possibly omitted by one of our authors, and he substitutes it (Billings, page 21) by a coil of hot-water or steam pipes. Morris (page 227) says that a hospital ward without a fire-place is radically and essentially imperfect. Where fire-places are prominently used, the plan of Folsom (pages 75-6) is excellent. Neirnsée (page 332) has a large open fire-place in every apartment of the Orphan Home, "besides auxiliary hot-water or steam heating —both systems of heating being combined with large air-flues for ventilation on the exhausting principle." He happily (page 338) recognizes the sun as a source of heat as well as light, and to be utilized. Most of the patent heat-mongers and routine hospital constructors assign it a very secondary place. We have thus many old and valuable suggestions, and spread ourselves before our old Baltimore heater in Calvert street, while our worthy trustees perspire over this temperature machinery. It will be noticed that dependence is placed upon no one system of heating, and our authors are suggestive and somewhat non-committal.

The bearing of heating upon ventilation is recognized as in most cases determining the source and method of heat. For instance, the fire-place seems as much vindicated as a ventilator as it is as a heater. It is

* HOSPITAL PLANS. *Five Essays Relating to the Construction, Organization, and Management of Hospitals.* Contributed by their Authors for the Johns Hopkins Hospital, of Baltimore. New York: William Wood & Co. 1875. 8vo, pp. 553.

true we have to bear in mind heat as a mode of motion, and also to remember that the difference of degree between outer and inner temperature is really the chief cause of currents and so of ventilation. But the fact is, in our vicious modern systems we come to endure too much artificial heat just because it is made the only dependence as the motive-power for ventilation. Heat is not as stifling as stagnant and impure air. We get to enduring and enjoying the former because it helps to rid us of the latter. It were far better to depend more upon some natural changing of air, or upon such artificial method as gives diffusion to currents independent of high heat.

We are in most of these plans striving too much after uniformity of temperature. We are very glad to find Morris (page 232) quoting these excellent sentences of Miss Nightingale: "Nature affords air to both sick and healthy, of varying temperature, at different hours of the day and night and season; always apportioning the quantity of moisture to the temperature, and providing continuous and free movement (of the air) everywhere. We all know how necessary the variations of weather, temperature, season are for maintaining health in healthy people. Have we any right to assume that the natural law is different in sickness? In looking solely at combined warming and ventilation to ensure to the sick a certain amount of air at 60° F., paid for by contract, are we acting in accordance with physiological law? Is it a likely way to enable the constitution to rally under serious disease to undercook all the patients day and night, during all the time they are in hospital, at one fixed temperature? I believe not. On the contrary, I am strongly of the opinion—I would go farther and say I am certain—that the atmospheric hygiene of the sick-room ought not to be very different from the atmospheric hygiene of a healthy house." Yet the great idea of the most of our artificial heaters is uniformity of temperature. In striving after this, the general result is a temperature too high. The variations that do occur are generally above 65°. A system of continuous parboiling results, which, like vice, after a time becomes endurable. Now, in such sick wards as these will be, most patients are in bed or have a bed readily accessible to them whenever desired. The bed is clothing, and itself affords facilities to the patient for regulating his temperature. The temperature of the inbreathed air is not the only source of heat to the patient. The fact is, wards are more apt to be accommodated to the sensations of attendants, who in night vigils and in their moving about are much more susceptible to cold than the patients in bed. Such persons should be clothed with special reference to their duties, and have over-sacks near at hand, so that a lower temperature can be prevalent.

Again, in most heating plans there is great omission to recognize the indispensable relation between heat and moisture which nature maintains out-of-doors, and which is so important to the sick inmates of hospitals. The degree of moisture needs to be accommodated to the degree of heat. If we use artificial heat we must also avail ourselves of artificial moisture. There is very little allusion to this point by our authors. Billings alludes to it (p. 20), although not explaining it in accord with physical and physiological action.

Absolute temperature is not the criterion of the caloric condition for breathing of the inspired air. It is important to know how far its capacity for moisture is met without the necessity of drawing upon each individual for the supply. "The moisture in the air," says Leeds, "is the great governor or regulator or conservator of heat." "It is like a soft invisible blanket constantly wrapped around us, which protects us from too sudden heating or too sudden cooling."

While excessive moisture is oppressive, excessive dryness is equally so. The state of invalidity in patients and the fact that the air is constantly being befouled by them more than by those in health, and that some of these foul gases have a different law of saturation from pure air, calls for astute investigation in this regard. While air passed over hot-water pipes does not largely lose its humidity at 60° or 65° F., yet in the condition of sick wards there is often need to add watery vapor. Carl Pfeiffer well says, "The most healthy state of the atmosphere can be obtained only when the dew-point of the air is not less than 10° nor more than 20° F. lower than the temperature of the room." The relation, too, of evaporation to the electric condition of every air needs to be studied, as urged by Hood. The uncomfortableness of very warm days is generally largely due to the air being saturated with moisture, and not to the absolute heat. Thus evaporation is interfered with. On the other hand, a very dry, hot atmosphere makes too heavy demand on the moisture within us, and is especially oppressive to the sick. There is need of constant testing as to the humidity of the prepared air of the hospital, and the hygrometer is as significant as the thermometer. The relation of the air inside and out to the dew-point must be constantly noted. The crawling foot-measure, mentioned by J. W. Draper (Text-Book of Chemistry), illustrates the significance of moisture, as does also Gardner, in his Medical Chemistry. Baked air is as deleterious as foul air. We have had occasion to use a portable hot-air furnace, and by extra water-pans, and by a water-basin of heated water hung in each register, or by water dripping from one to another, are able to modify the inspired air. The Winans method for moisture, as well as for heating, is worthy of careful study. In the climate of Baltimore we incline to fire-places and grates, as suggested by our authors, and to having for each ward in reserve a separated heating arrangement, by which air that has been heated by contact with steam or hot-water coils outside, may be introduced

into the ward when required. We believe a proper system of heating will yet come to introduce this heated air through many apertures, rather than through two registers to a ward.

The proper diffusion of heat probably also requires that it should both enter and have apertures for exit towards the floor, rather than the ceiling, or at least scattered about here and there.

Many of these questions must still be considered as *sub judice*, and upon them this hospital may aid in securing valuable information. The great trouble as to heating and ventilation as well, is that we have been depending too much on what we call the experience of doctors, architects and engineers. These are valuable as correlative and accessory. But many an architect gives a tasty plan and many a physician makes a good round through a hospital without their opinions being of much value, when from their noses and feelings they elaborate unlearned dicta as to the atmosphere within. This has to do with that close observation and record of science which belongs to the close sphere of physics. We want definite tests and experiments, such as Franklin made about electricity, or Wells on dew, and to depend upon series of authenticated experiments in the hands of skilled manipulators. We are glad to see this point alluded to by Billings (p. 32), and to be assured that it is easy to have a series of dials which will show at a glance the temperature and the amount of air passing through the various heat and foul-air ducts. To these we must add various kinds of hygrometers, barometers, anemometers, etc., and test moisture, rapidity and diffusion of currents, electric condition, and all those points now so well recognized as somehow bearing on health and on recovery from sickness. The remark made (p. 4) as to clinical observation has a wider range.

It is by the application of "instruments of precision and of graphic measurement" that we are yet to arrive at definite laws as to heat, moisture, ventilation, as to all conditions of inbreathed air, and come to know it in its bearings on household life.

We are equally concerned with the one who has charge of the heating of wards as we are about the apparatus. Tools are grand, but it is the operator that tells of their practical utility. We want an engineer who is also a scientist, and who will be as expert in all this department of natural philosophy as the surgeon is in applying the laws of human waste and repair. We notice that among the officers of the House of Representatives there is an engineer of ventilation at $1,800 per year; three assistants, $1,440 each; and six firemen of ventilation, each $1,095. We would just like to have them up for competitive examination before a board consisting of a professor of physics, a chemical professor and a practical operator we know. We would just like to know the results of their observations, and what evidence there is that what are called by them "observations" amount to anything scientifically, which means practically. We hope the trustees of Johns Hopkins Hospital will not so far adopt any one plan, but that under experts they may ventilate these subjects, and give us series of graphic observations, etc., which will cost no more than these, and result in determining questions of great concern to all valetudinarians.

In all this, too, it is ever to be borne in mind that each person properly handled is a heater, that all his garments are heaters, that the properly constructed hospital is a heater, that the chimney fire is a heater, and that the special appliances for heating are to be regulative and supplementary merely. The demand for them is by every possible means to be reduced to a minimum and then to be superintended by high skill, because the indication for use is so relative. Blessings be upon the men who in hospitals abate artificiality everywhere except so far as it supplements the ability and availability of elemental forces.

Heat is so much a mode of motion and therefore so correlative to ventilation, that it is difficult to consider the one separate from the other. When we come to inquire as to the modes of exit of the heated air, the two are inseparable. This relation in a hospital is practically all the more intimate, because, as Lanchester, in "How to Make Homes Healthy," remarks: "One result of the poisoning of the blood by impurity of air is the extreme susceptibility of the system to cold."

It must first of all be understood that nothing can wholly supersede natural ventilation, and hence windows, doors, chimneys and the ventilation through structure indispensable, so far as are consistent with avoidance of draught and a healthful temperature. In a country house where each room has a fireplace, or where a wrought-iron stove receives its air at the bottom from the room or from an outer tube and distributes it warmed above the cylinder, there need be but little trouble as to purity and warmth of air. Leeds, in his book on ventilation (p. 25), has well illustrated the simplicity and success of the arrangement, and also that some of the outcry about stoves is frivolous.

But in a hospital filled with abnormal conditions arising from continued occupancy by sick people, dependence cannot be placed upon natural ventilation, or upon the simple methods of country households.

Our authors treat ventilation *in extenso*. Billings guards the point that letting in and letting out air is not always thorough distribution, which is necessary to good ventilation. He associates ventilation with the heating, and claims that letting in the warmed air at the top (p. 22) and drawing out the air at the bottom secures the best diffusion, which, in common with Franklin, Leeds, etc., we very much doubt. The method of introducing and removing the air at the bottom as in Barker's ventilator, does not strike him favorably. He would introduce the air high up, or

both above and below (p. 30), and have an aspirating shaft so constructed as to suck out the foul air from the sides and corners near the floor. Ridge ventilation is also availed of.

Folsom (pp. 76 and 81) accomplishes artificial ventilation by a central chimney-stack, and by 12 ventilating ducts scattered about the ward near the floor in the walls, connecting with the chimney as an aspirating flue in the basement. On page 82 these openings are spoken of as beneath the patients' beds, and the process of admixture and removal of air described. Heated air is introduced by two registers alongside of the chimney-stack, the air being heated by a boiler and heated coils. The system is that of introducing heated air at the bottom, and letting it out at the bottom. The chimneys are helps both as heaters and ventilators, and there are two ventilators in ceiling for special use when required. The low specific gravity of the entering warm air is relied upon to carry it upward. It is then regarded as cooling, and descending along the walls so as to seek the apertures and obtain exit.

Jones (p. 122), besides fire-places, would supply the wards by fresh-air boxes heated by coils of hot-water pipes. He thus introduces the warm air at the bottom, as is more fully explained by Parkes. He leaves the breathed or changed air to escape by fire-places and windows, and to be disinfected by tar water. He is almost as enthusiastic over Berkeley's "Siris, or the virtue of Tar," as was Prof. Fraser, who calls it "the great work of the age on pure philosophy, and one which connects tar with the highest thoughts in metaphysics and theology." Dr. McCosh thinks otherwise, and says, "I cannot discover any higher logic than quacks employ in recommending their medicines." We like tar as a disinfectant, and value it more than some more popular smells, but still think more attention due to removal.

Morris (pp. 226–30) magnifies with enthusiasm the value of fire-places both for heating and ventilation, and with the Galton modification, by which cold air is introduced behind them, and heated so as to be used through apertures half-way toward the ceiling, he shows them to be largely available. He also would have similar flues in the side walls with openings at ceiling and floor, to be opened or shut as required, and to be used when there is no fire in the chimneys. He would secure a draft by connecting them above with a central smoke-stack. He would also have foul air removed upon the Barker plan near the floor.

In addition he would have heat supplied near the floor from steam-pipe radiators outside the wards, the same as other of our authors, with the difference that he prefers "high-pressure" as more easily regulated and more certain. He would have a fan provided to secure air to these radiators when needed, as it seldom would be.

Smith (p. 309) speaks of three kinds of ventilation: 1st. Natural, *i.e.* by windows, doors, and chimneys. 2d. Vacuum or exhaustion of air by heated shafts (aspiration); and, 3d. Plenum or fan propulsion.

He would rely entirely on natural ventilation in one-storied wards (p. 313), and combine vacuum and plenum ventilation in other structures. In the vacuum method he would still have the suction of foul air chiefly through heated chimneys. In the third the air is driven into the wards by a fan, being heated in winter and cool in summer. He does not specify at all at what points heated air is to be introduced or outlets provided. In fact, he relies so much on the warming of the structure itself, and on chimneys, as to leave the rest mostly to natural ventilation, and cautions against too elaborate apparatus.

He would have the wall-space warmed, and not depend much on inside ward arrangements, and does not discuss the bearing of this heated wall condition on inside ventilation.

Neirnsée (p. 332) relies on natural ventilation, fire-places, and large air-flues for ventilating on the suction or vacuum principle. His method of preparing and introducing heated air is by registers connecting with hot-water radiators below. He has (p. 360) a central chimney and ventilators in the basement of each ward, and by separate pipes for the smoke inside of the chimney makes of the rest of it an aspirator for drawing out the foul air of the wards through openings at the floor.

For summer ventilation all of our authors who refer to it rely upon the fan as most available when natural ventilation fails. It should be remembered, however, that the fan is applicable in colder weather as well as in hot weather, as a substitute for excessive heat, as a motor or ventilator. In the Kirkbride Asylum the fan is relied upon both in summer and in winter, and is spoken of as a substitute for the central chimney-stack or for fire-places. See Reports of Penn. Hospital for Insane, 1859, 1868, 1873, 1874, in which are many valuable hints on this subject. Because heat is so much a mode of motion, in most public buildings it is relied upon too much, and propulsion too little, for ventilation. Overplus of heat is more endurable than stagnant, foul air, and the occupants are refreshed by over-heat, not because it is good, but because it serves to diffuse, distribute, and expel the befouled air, and so is a constructive good. So at length the patients come to enjoy the contrast. It would be far better to get the same result without this lesser evil. Fans and housetop wind-mills, it may be, are yet to be studied very much as to ventilation. There are really but two methods of ventilation: that made by difference of temperature in adjacent strata of air, and that by mechanical forcing or disturbance of air. What is called the vacuum or exhaustive method by heat is merely making one body of air of different temperature from another, and so causing suction and distribution. The plenum or fan-propulsion method seeks to secure motion with a less degree of heat or mechanically. Natu-

ral ventilation partakes of the character of each. The fan, as used in winter, also serves to bring air more rapidly in contact with radiators, but we are not to lose sight of it as then combining ventilation by heat and mechanical action both. We are to study how much it can be made to do the one or the other in different proportion, according to the demand of locality and of the state of weather on any one day. The adjustment of all these plans to each other is the art of ventilation. The scientist defines with precision the laws. The expert being informed as to these laws operates the machinery, adjusts the relations, and then we get experimental knowledge. That we expect to get from Johns Hopkins Hospital.

As to the points for introducing warm air or propelled air, and the points for providing exit for used-up air, we are more and more led to the view that these should be many. Whether these apertures should be, some at the ceiling and others at the floor, or whether both should be below or both above, has been largely discussed. Our authors mostly incline to both entrance and removal near the floor. We think experiments have shown that Franklin was right in his stove theory, and that a room becomes equally warmed by the warm air spreading to the ceiling, and being displaced by new columns of warm air, and so circulating down the walls and through the room. If a ward is intensely foul we can see reasons why, at a great loss of heat, all heated air should be allowed to escape at the ceiling or by ridge ventilation, but, under usual circumstances, diffusion is safely secured by its removal upon descent. Really, however, the openings should be, for ingress and egress, neither above nor below, but all around. This whole subject of heating and ventilation needs to be restudied in its natural laws, and then principles applied with scrupulous exactness and with testing. Pettenkofer, in his lecture on "The Relations of the Air to the House we live in," says more in ten pages than most do in fifty, just because he tests principles, and is an experimenter in hygiene, instead of a mere nose-ologist as to the odor and purity of air. Our subjective impressions are sometimes of little worth. Give us a ward right in its structural composition, with windows, doors, and fire-places properly arranged, and some one with thorough sense to manage them, with such airing, sun heating, and cleanliness as may be secured, and in Baltimore the apparatus for heat and air need not be complicated. A wrought-iron portable heater in the basement, with proper adjustment of jacket air-space and pipes, costing $300, might shock the furnace foundries, but we could get good regulative heat out of it. Give us somehow a fan of simple construction, which could be worked when required, and communicate with the ward at various points, and out of it, too, in summer and winter, we could get ventilating comforts. If the walls are hollow, chimney-like flues through these, with a gas light somewhere in them, and a small fan arrangement inside, attached to a moving power, would make a draught in summer of much service. We think the subject of summer regulation in Baltimore needs far more study than the winter.

The relation of lighting to heat and ventilation has not been sufficiently discussed by our authors. A single French hospital has more than 1,000 gas-burners, and each gas-burner consumes as much oxygen and gives off as much carbonic acid gas as five persons. The amount, too, of heat is very great. The necessity of a right sort of burner, of a constant, subdued light at night, and of such lowering as will not cause imperfect combustion, needs attention. Lamps too often need to be used at bedsides. Great use can be made of gas-light and gas-heat for ventilation. The whole subject is treated by Hammond in his book on hygiene. His essay on construction of hospitals, like that of Lee and several others, is well worthy of study, beside those of our authors. Night vigilance over hospital heat and air is less operative than in the day-time, and patients often suffer greatly from conditions which are more carefully watched in the day patrol of physicians and wardens. We hope some day some Yankee will build a ward which will be divided by a movable glass partition easily raised, like an elevator, and only one half occupied by day and the other half by night. The beds could all be on an impervious platform on each side, and so attached to power outside, that at a given time the whole would move without a jar into the adjacent part, leaving each room alternately vacant.

This whole work brings us in its every section more and more to realize that the exactness of physics and of good housekeeping are the foundations of hospital success. The household system will yet come to be the prevalent idea of hospital construction and hospital management. We want a neat hospital village in which each classified kind of disease has its home. Then let it be regulated and administered as would be the household of a man and his wife who had twenty five relatives sick under their charge with one disease, and with ample means for proper nursing and care of them. This is the higher "secundum artem" we need, both as to construction and organization. The dusting of furniture and walls, the cleansing of wards and scrubbing only for soiled spots, the vacating of rooms as often *in proportion* as the good house-wife would have genuine house-cleaning, the proper airing of beds and bed-clothing, the regulation of transom windows and sky-lights and warmth—these and many other points not easily pencilled out in detail, but easily secured by the efficient housekeeper, these are the details of administration which to us promise more than one grand administrative building, with corridor connections to divers offsets, with general assembly-rooms for attendants, with an all-pervading heating and ventilating apparatus, and a sewerage which links them all into one.

In the notice of this valuable book we have been compelled to deal with suggestions rather than to enter upon discussions. and so have but imperfectly set forth reasons, and omitted much that waits to be said.

We have been compelled to pass over many points, such as furniture, chapel. amphitheatre, dead-house, autopsy tables. bedsteads, bath and water houses, fire-escapes, etc., because crowded out by more leading questions. We have studied these various plans among themselves and in compare with other sources of information, and welcome this contribution to the science of construction in general and hospital administration in particular. It is not wonderful that in so broad a theme some points should have been overlooked or dwelt upon too briefly, or that room should be left for other plans and modifications. We hope, and believe, that Johns Hopkins Hospital will be benefited by these essays of our authors, Billings, Folsom, Jones, Morris, Smith, and Niernsée, and will in its construction and orderings be so fortunate as to command the results of the closest science and the most taetile art. Engineers must study more than levels, and architects more than artistic effect and convenience. Physicians must get hold of the therapy of hygiene more wonderful than that of Materia Medica, and nurses know that their specialty can have no other foundation than a full knowledge of all the elementary branches of good housekeeping. Uniformity of plan must yield to classification and segregation both of disease, and of the attendants. Effort must be made to secure to each sick one a sheltering home, where in summer and in winter, by day and by night, art shall see that all vital and normal forces of nature have due play around as well as in the patient, and then only as handmaid give its kindly helping hand.

In this beautiful city, to which we are attached by other, as well as hospital memories. we shall watch with interest the rising of the model hospital, the model medical college, and the model university, as the devotees of education and of science watch any progress which means a higher standard of excellence and with it benefit to all humanity.

The endowment is in worthy hands, and the chosen president is skilful in organization and operation. With intelligent co-operation, and a zeal according to knowledge, an expectant people feel assured these gentlemen will well plan and well equip the uprising structures of this wonderful philanthropy.

The present number contains the concluding article on Hospital Construction and Organization. There were so many questions connected with the subject, and such an opportunity for discussing them in their application to the proposed model hospital of Baltimore, that we have considered it necessary to present them in detail. In order that no other material may be crowded out by the length of the article in this number, we have added some extra pages. Although averaging more than the usual editorial space devoted to such subjects, we hope that the general interest in the different topics may warrant the course pursued. These articles were originally written as an elaborate review of the work in question, but they so entirely accorded with our own views, that, contrary to our usual custom, we concluded to use them as editorial articles. It is but just to say in this connection, that the author is Dr. Ezra M. Hunt, of Metuchen, N. J., whose articles on House Hygiene and kindred subjects have attracted so much attention among sanitarians.

PHYSICIANS' PRESCRIPTIONS AND DISPENSING CHEMISTS.

So much depends upon the care and honesty with which our prescriptions are compounded by the apothecary, that every prescriber would fain believe that wilful mistakes or fraudulent practices are impossible. This is the charitable view of a question which has a very wide-spread bearing, not only upon the good of our patients, but the science of therapeutics in general. When a physician orders a certain quantity of a drug, he naturally expects that the order will be duly executed in every particular, and unless there is a palpable mistake in the dose of the drug, which makes poisoning possible, he does not appreciate the necessity of any comments, or any suggestions on the part of his compounder.

It would be well if all such expectations could be properly met, and there be no necessity for reflection upon the assumed high-mindedness of a certain class of so-called pharmacists. To the credit of the profession which they assume to represent, we are glad to know that they are few in number, but that these few exert a bad influence upon the majority of good men and true, who wish to cultivate the "prescription business" on thoroughly upright principles, is too apparent for comment. We have recently heard of apothecaries who not only openly criticise the prescriptions that may accidentally drift into their shops, but presume to substitute something which they consider better. Not long ago a well-known gentleman of this city, who has special reasons for prescribing large doses of quinine, wrote one of his prescriptions containing that drug. The patient, on presenting it to an apothecary in his neighborhood, was quite startled to learn that he was about to take a poisonous dose. Not satisfied with this comment, the compounder volunteered the advice not to take the medicine in the quantity ordered. This is but one of many instances of the sort which occasionally come to our notice, and to put the case mildly, might be looked upon as "unwonted interference." In the event of the prescription being accurately compounded, the patient is free to choose between the advice of his physician and that of his apothecary. If there were any doubt in the mind of an honorable apothecary as regards the safety of a

patient taking a large dose, the course to be pursued is so apparent that we hardly need refer to it. In all such cases of interference by the apothecary the physician generally protects himself from aspersions on his professional skill by advising his patients to go to another shop, and the difficulty is promptly and effectually remedied. If, however, the compounder chooses to go further, and either for the good of the patient, or what is more likely, for the good of himself, lessens the quantity of the drug in the prescription, or substitutes it for something which he thinks equally good, the physician and patient alike become the victims of the most despicable of frauds. The temptation for fraudulent dealing in this respect is particularly great when the ingredients of the recipe are very expensive. We have known that the substitution of one article for another is possible in the making up of prescriptions in some of the drug-shops of this city, but have no positive knowledge regarding the actual reduction of quantities of different articles ordered. That such things, however, may occur in well-regulated communities, we have proof in some recent developments concerning the doings of some of the apothecaries of Sheffield, England. It seems that some anxiety had existed on the part of the practitioners of that place as to the care and accuracy with which the prescriptions were dispensed. To test the matter, the inspectors of the health department presented to certain local druggists some prescriptions, which were so arranged that each should contain a full dose of some expensive remedy, capable of ready and accurate quantitative estimation in a mixture. Iodide of potassium was selected for that purpose, and in each of three prescriptions one hundred and twenty grains of the salt were ordered. While two prescriptions contained the full quantity, there was only seventy-six in the third. Of three samples which should have contained sixteen grains of quinine, one contained only nine and a half grains; and another sample, which should have contained forty grains, contained only thirty. The reduction in the quantities might have been much greater, but violation of the principle of fair dealing is the same, whether the transgression is great or small.

Concerning this particular case, *The Lancet* (Jan. 15) speaks as follows:

"It is, of course, wrong to tamper with or 'devil' any prescription, but when iodide of potassium or quinine, and a few other drugs whose actions are so thoroughly understood, are concerned, it is almost criminal. It may appear a strong statement, but there are cases in which a patient's life may depend on the quantity of iodide of potassium taken, and almost as much may be said in some cases in which quinine is ordered. Curiously enough, it is generally in those instances in which large doses of these remedies are ordered that it is of the greatest importance that the full dose should be administered."

Reviews and Notices of Books.

A Treatise on the Diseases of Infancy and Childhood. By J. Lewis Smith, M.D., Physician to the N. Y. Infants' Hospital, Physician to the Catholic Foundling Asylum, etc., etc. Enlarged and thoroughly revised. Phila.: H. C. Lea. 1876. 8vo, pp. 716.

This work took a stand as an authority from its first appearance, and every one interested in studying the diseases of which it treats is desirous of knowing what improvements are apparent in the successive editions. In the second edition a great amount of new material was added, including many diseases not alluded to in the first edition. The alterations in and additions to the volume alluded to were quite apparent, but with two or three exceptions in the present volume, the various additions and improvements are not noticeable to the superficial examiner. The principal additions to which we refer, and which will be the distinguishing features of the third edition, are the chapters on diphtheria, cerebro-spinal meningitis, and rötheln. The former disease is considered much more in detail than formerly, and a great amount of very practical information is added. The author is not a believer in the bacterian theory of the origin of this disease, but is inclined to the opinion that the development of micrococci is a consequence rather than a cause. This opinion is founded upon the fact that he has observed this micrococcus in abundance in non-diphtheritic exudations. The whole article on this disease has been virtually re-written, in order that the author's experiences in the late epidemics might be duly presented; and altogether it is one of the most comprehensive and one of the best written chapters on the subject that we have thus far read. His description of cerebro-spinal meningitis, founded also for the most part on personal experience, is admirably clear and exhaustive. His remarks upon rötheln are necessarily short, and are mainly confined to a notice of its anatomical characters as distinct from those of ordinary measles and scarlet fever, with both of which diseases it has sometimes been confounded.

Medical Diagnosis, with Special Reference to Practical Medicine, a Guide to the Knowledge and Discrimination of Diseases. By J. M. DaCosta, M.D., Prof. of Practice of Medicine and Clinical Medicine at Jefferson Medical College, Phila. Fourth edition, revised. Phila.: J. B. Lippincott & Co. 1876.

A fourth edition of this work has just been published, and as far as we can judge from a cursory examination of its contents, all the necessary changes and additions have been made to bring it up to the requirements of the present time. The principal additions have been incorporated in the chapters on nervous diseases and fevers. The work, as a whole, is in our opinion without a rival.

Lectures on Bright's Disease: delivered at the Royal Infirmary at Glasgow. By D. Campbell Black, M.D., L.R.C.S. Edin., etc. Phila.: Lindsay & Blakiston. 1875. 8vo, pp. 146.

This volume comprises a series of six lectures on Bright's disease of the kidney, delivered at the Royal Infirmary of Glasgow, and afterwards published in the *Medical Press and Circular*. In the present form they have been revised and amplified, and cannot fail to be

acceptable to every busy practitioner who has not the time to consult a large treatise. The subject is very interestingly, comprehensively, and practically treated.

TRANSACTIONS OF THE COLLEGE OF PHYSICIANS OF PHILADELPHIA. Third Series. Vol. I. Phila., 1875. 8vo, pp. 190.

ALTHOUGH a work of small size, it contains a large amount of very valuable material. The various topics discussed give the volume an attraction to almost every one interested in the curious things in medicine or surgery. Every one of the twelve papers published is worthy of a place in the volume, and amply repays a careful study. Having said thus much, we present our readers with the following list of the articles. I. Report of an Autopsy on the bodies of Chang and Eng Bunker (Siamese twins), by Harrison Allen, M.D. (illustrated). II. Case of Adenoid (Hodgkin's) Disease, etc., by James H. Hutchinson, M.D. (illustrated). III. Fracture of Neck of Scapula, by John Ashhurst, jr., M.D., etc. IV. New Operation for certain Cases of Cleft Palate and Bifid Uvula, by Wm. S. Forbes, M.D. (illustrated). V. Excision of Elbow, etc., by John Ashhurst, M.D. (illustrated). VI. Experiments on Laryngeal Nerves of Muscles of Respiration, etc., in a criminal executed by hanging, by W. W. Keen, M.D., etc. VII. Nitrite of Amyl in various Forms of Spasm, and its Value as an aid to Diagnosis, by S. Weir Mitchell, M.D., etc. VIII. Case of Acute Tetanus treated by Nitrite of Amyl, by Wm. S. Forbes, M.D., etc. IX. Remarks on Diabetes Insipidus, by J. M. Da Costa, M.D. X. Report on Surgical Considerations in regard to the propriety of an Operation for the separation of Siamese Twins, by Prof. W. H. Pancoast, M.D. (illustrated by chromo-lithographs). XI. Encysted Dropsy of Peritoneum, Suppuration, Abdominal Section, and Recovery, by J. Ewing Mears, M.D., with remarks thereon by Dr. Wm. Pepper. XII. Quinine as a Stimulant to the Pregnant Uterus, by Albert H. Smith, M.D. The present volume begins the third series, and contains the papers read before the College from April, 1874, to June, 1875, inclusive.

A TREATISE ON HUMAN PHYSIOLOGY; designed for the use of Students and Practitioners of Medicine. By JOHN C. DALTON, M.D., Professor of Physiology and Hygiene in the College of Physicians and Surgeons, New York; Member of the New York Academy of Medicine, etc., etc., etc. Sixth Edition, revised and enlarged. With three hundred and sixteen illustrations. Philadelphia: Henry C. Lea, 1875.

THE volume before us is a revised and enlarged edition of a work which has been used for several years as a text-book on human physiology. The reputation of Prof. Dalton as a careful teacher and methodical writer insures a hearty welcome to the present edition of his book, which contains fully fifty per cent. of new material. In taking a general survey of the work, we find that the arrangement remains preserved which obtained in the last edition; but as our comparison goes on by pages and chapters, we find that, in many places, the old text has been rewritten, as well as additions made such as were necessary to render it a fair exponent of physiological science up to the date of its publication. The successive changes which have been rung upon physiological problems within the last decade, especially upon those relating to the circulation, the lymphatic and nervous systems, have necessarily made the labors of the conscientious teacher and author most arduous. Even experts have been perplexed in their attempts to separate the few grains of truth from the huge pile of dirt and chaff which has been thrown out by European and American experimenters. Upon the labors of these experts, however, the medical student and the practitioner are obliged to rely for physiological sustenance. He, therefore, who embodies in a book that which can be easily digested and readily assimilated, and at the same time nourish, and can also produce material that shall stimulate and encourage without leading to positivism upon the one hand, or to regard physiological science as altogether uncertain upon the other, must have keen powers of discrimination and a filter which, unfortunately, every author does not possess. In this respect, however, we believe that the writer of the book before us has succeeded to a degree which will yield him the general approbation of the profession.

Prof. Dalton has discussed conflicting theories and conclusions regarding physiological questions with a fairness, a fulness, and a conciseness which lends freshness and vigor to the entire book. But his discussions have been so guarded by a refusal of admission to those speculative and theoretical explanations, which at best exist in the minds of the observers themselves as only probabilities, that none of his readers need be led into grave errors while making them a study.

So much for a general inspection of the work. We will now review it a little more in detail, and direct attention to a few, and only a few, items, which the reader, if he chooses, may regard as criticisms. We are not studying the book, however, as does an advanced physiologist when called upon to expend his powers of criticism, but are endeavoring to read it as does the earnest medical student and practitioner. We open the book at random, and find that we are brought face to face with what the author has stated regarding the anatomy of the organs of respiration. The first item that attracted attention was the failure to mention the ciliated epithelium in the anatomical description of the bronchial tubes.

A little farther along we came to the "movements of respiration." Under this head are discussed the movements of inspiration and the movements of expiration, and we are taught "that only a small portion of the air in the lungs passes in and out with each respiratory movement; and it will require several successive respirations before it can be entirely changed." Now just how the air in the deepest portions of the lungs is renovated is not stated. This is certainly an important physiological question, and we were disappointed in not finding some reference made to the agencies which are at work in that direction. While reading the same pages we became aware of the fact that the author has adopted the metrical system of weights and measures. Although this system has had the signet of English legality for more than twelve years, we believe that Prof. Dalton has erred in using it, just at present, in a text-book for students and practitioners, and that it will prove unacceptable to the majority of American readers. The author would have given incalculable aid to the general practitioner (who likes to find things in a nutshell), had he appended a table containing the value of the terms used in the metrical system, expressed in inches, ounces, pints, etc., etc.

In Chapter XII. are presented the theories of Denis and Schmidt with reference to the nature of the process of coagulation of the blood; but with the tact of a careful observer the author does not fully adopt or entirely reject either.

As we open the book again we notice that Prof. Dalton still adheres to the belief that the heart lengthens in ventricular systole. We had supposed

that this question was settled, and that it had been generally accepted as a fact susceptible of mathematical demonstration, that the ventricular cavities necessarily shorten during systole.

Again, we notice in the chapter upon the circulation that no reference whatever is made to the safety-valve action of the tricuspid and pulmonary valves, which is an item of considerable practical interest to the student of thoracic diseases.

The section devoted to the subject of reproduction contains one of the simplest, most elegant and comprehensive descriptions of this process to be found in the English language. As a matter of course these chapters could have been made much more elaborate, but they are sufficiently so to meet the demands of the ordinary medical student and busy practitioner. These are some of the suggestions noted while reading the sixth edition of this valuable treatise upon human physiology.

Transactions of the American Neurological Association for 1875. Edited by F. P. Kinnicutt, M.D., and T. A. McBride, M.D. Volume I. New York: S. W. Green, Printer, Nos. 16 and 18 Jacob Street.

This is the first volume of the transactions of a new medical organization, and contains the minutes of the proceedings, the constitution and by-laws, together with the papers read at the first session, and the discussions to which they gave rise. The volume contains 257 pages, and has been prepared with a care which entitles the editors to the thanks of the Association. The plates accompanying some of the papers are exceedingly good, and will serve as valuable aids to the specialist, as well as to the general reader. The average merit of the papers is quite high.

The Student's Guide to Human Osteology. By W. W. Wagstaffe, B.A., F.R.C.S., Assistant Surgeon, etc., and Lecturer on Anatomy at St. Thomas's Hospital. Philadelphia: Lindsay & Blakiston. 1875.

This little volume of 349 pages of text-matter is the result of an effort, the author tells us, to give a brief, but clear description of the bones of the body, and at the same time to interest the reader by attaching points of practical importance to the various bony landmarks. In these respects the author appears to have fulfilled the object he had in view, and the descriptive portion of the work gives a fair résumé of what is found in most text-books. In the matter of bone-structure, however, we have a good deal that is new, being mostly the result of recent inquiries made by the author and others into the bony fibres, and their adaptability to sustain the peculiar tasks assigned them. Illustrations are numerous, both by lithographic plates and woodcuts. The former are mostly new, though the disadvantage of having them on separate pages is felt, as they are often far away from the text. Many of the woodcuts have been borrowed, chiefly from Ward. Those prepared for the author are often very poor, and are scarcely any addition to the value of the book. There is a certain carelessness of "get-up" about them that might have been avoided, though, as the author says, illustrations, whatever their beauty or correctness, can never supply the information to the student that the bone itself does, when held in the hand. The last eighteen pages give us a very useful summary that may be read with profit by student or practitioner. In it we have a description of the important bony points of the body such as can be felt with the finger, and their relation to various other important parts, that are to be borne in mind in matters of physical diagnosis, or when operative interference is required.

A Manual of Minor Surgery and Bandaging. By Christopher Heath, F.R.C.S., Surgeon to University College Hospital, etc. Philadelphia; Lindsay & Blakiston. 1875.

This little volume of some 300 pages, which has now entered on its fifth edition, is, as its author tells us, designed for the use of those who wish to master the smaller details of surgery, and so to prepare themselves for the numerous accidents and emergencies that are met with in hospital and dispensary practice. The author's experience as a dresser and house surgeon enable him to appreciate the value of just this kind of information, which is apt to be omitted in the larger text-books. Special rules are laid down for case-taking and for conducting post-mortem examinations. To these are also added a long list of formulæ in use in the London Hospitals, and some of the diet lists for patients. Altogether this little manual will be found very readable, and will carry useful information not only to students, but also to young practitioners who have not had the advantage of hospital training, and perhaps to others who are not specially familiar with the most recent advances made in this department. The illustrations are good, and are sufficiently numerous.

Outlines of Practical Histology; being the Notes of the Histological Section of the Class of Practical Physiology held in the University of Edinburgh. By William Rutherford, M.D., F.R.S.E., Professor of the Institutes of Medicine in the University of Edinburgh, Examiner in Physiology in the University of London. Philadelphia: Lindsay & Blakiston. 1875.

A handbook which acquaints us with the most recent methods of microscopic work is always to be prized, and especially if the matter be condensed in the least possible compass and is from the hands of an experienced teacher of microscopy. The bulky treatises on this subject have done a great deal to frighten away many who would have been glad to familiarize themselves with histological work. To such we would recommend these outlines, as showing in very simple words what is required in getting a knowledge of practical histology. The subject-matter is discussed in about seventy printed pages, while for convenience in taking notes, each page is interleaved. The author's familiarity with the subject enables him to give only those methods of work that long experience has shown to be the best. Though he has not contributed much that is new in the way of methods, he appears certainly to have done a great deal towards facilitating the work. The freezing microtome he describes gives promise of much success. It is exactly the instrument that has long been needed for preparing fresh tissues, especially nerve elements, and other delicate substances for early examination. Such an instrument, if cheap enough, will certainly come into very general use.

Uronology and its Practical Applications. By George M. Kober, M.D. Louisville, Ky., 1875. Reprinted from the *Richmond and Louisville Medical Journal*, September, October, November, and December, 1874.

This is an unpretentious pamphlet of about 100 pages, but contains, nevertheless, a good deal of valuable information drawn from reliable sources. The author discusses the characters of healthy urine, and describes its most important ingredients, and gives many good processes for their detection and quantitative deter-

mination. He describes the processes, however, a little too nakedly, and fails to give the necessary hints and "wrinkles" which the physician who is not already practically familiar with chemical manipulations should be acquainted with, to enable him to perform the necessary analyses successfully. For the determination of urea he recommends the old processes of Liebig and Davy, but fails to allude to the "corrections" which must be applied to the results obtained by either of these procedures. He makes no reference to the more recent and convenient, and probably more accurate, methods of Boymond, Piffard, and Yvon.

In but one place only we have observed a manifest error. Its importance, however, induces us to notice it. On page 29 we find: "The specific gravity is best taken by measuring 100 cc. of urine into a beaker or flask, whose weight is accurately known. The increase of weight in grains will be the specific gravity, water being 1000." If this were followed out, urine whose real specific gravity was 1.020, would appear to have a specific gravity of 1.308. The substitution of the word *grammes* for *grains* in the quotation will make the procedure correct. As the *metric* system is employed in the various analyses, we presume the "grains" is a misprint.

The author describes the microscopical appearances of urinary sediments, and illustrates them by means of reproductions of the lithographic plates of Vogel, Funke, etc. He discusses the pathological conditions associated with derangement of the urinary secretion, and gives many useful hints in connection with their management. Finally, he incorporates Thudichum's scheme for the systematic analysis of urine.

The importance of urinary examination is too often underrated, and the author deserves credit for calling the attention of the profession to the methods by which it may be successfully undertaken.

SANITARY AND MEDICAL REPORTS FOR 1873–74, by Officers of the United States Navy. Prepared for publication under the direction of the Surgeon-General of the Navy. By H. C. NELSON, M.D., Surgeon U. S. Navy.

UNDER the above title the Bureau of Medicine and Surgery has issued an octavo volume of eight hundred pages, comprising seventy-eight articles contributed by medical officers of the United States Navy. These reports embrace the subjects of hygiene in its application to ships-of-war and naval hospitals, medical topography of various foreign cities and countries, descriptions of foreign hospitals, accounts of certain rare drugs, and miscellaneous medical papers. The variety of subjects discussed in these pages is so great that our limited space precludes even the mere enumeration of them.

The appearance of such a creditable work, which excels its two predecessors both in interest and style, is an earnest of future production of still greater merit. The medical officers of the navy have for years labored under great discouragement. The bureau, since its establishment in 1842, has been plunged into Rip Van-Winkle slumber, disturbed only by its solicitude to discover the smallest quantity of beans and "junk" a sick man might be made to subsist upon, and their exact cost. Great importance was given to the expression of these two facts—quantity and cost; mathematically and sore were the trials of the medical officers in wrestling with decimal millionths and tens of millionths to arrive at the desired result, as an error of a millionth brought return of papers with the "returned for correction," and a lengthy correspondence. The real vital interests of medicine and surgery never dawned upon the bureau during its brief intervals of awakening. This state of affairs grew, in great measure, out of the lamentable mistake of political and religious interests determining the appointment of the least experienced and intelligent of the corps to the office of Surgeon-General, so that it was not surprising that blankets went to Africa, quiniæ and cotton goods to Labrador, and hospital supplies shipped after, instead of before, battle.

The same benighted policy withheld from medical officers all means of medical and scientific research that involved any expense. The instruments were, as a rule, bad, the medicines unreliable, and the surgical appliances of the meanest, cheapest, and most ancient sort. Thus all spirit of emulation was crushed out. The contributions of the bureau to medical science were restricted to the annual flatulent reports, barren of all utility except, perhaps, to puzzle children with decimal conundrums.

This state of things endured until the close of the war, when Dr. Wood, a gentleman of large experience and fine mental culture, succeeded to the bureau, and immediately inaugurated a new era, completely revolutionizing the arrangement of his predecessors. Supplies of the best materials, all the most improved appliances, were freely furnished, and medical officers were invited to make reports for publication, and, for the first time, prominence was given to purely medical interests. This policy has even been greatly amplified by Surgeon-General Beale, under whose fostering care the third volume of the bureau's series now appears. The superintendence of the work through the press has been entrusted to Surgeon H. C. Nelson, U. S. Navy, and the creditable manner in which he has acquitted himself will be revealed by the examination of the volume itself.

We are informed that the limited means of the bureau has restricted the edition to comparatively a small number, and far inadequate to the demand that will be made. This is much to be regretted, as its pages contain information that should be within reach of physicians throughout the country.

Reports of Societies.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, January 12, 1876.

DR. F. DELAFIELD, PRESIDENT, IN THE CHAIR.

EMBOLIC SOFTENING OF THE BRAIN, WITH INFARCTIONS OF THE LUNG.

DR. SATTERTHWAITE presented the brain, right lung, and heart of a patient who had the following history:

He was first seen by the attending physician on November 17, 1875. Two days previously he had suffered from headache, referred to the occipital region, and the pain was so severe that he had to leave his business and return home. His wife gave him some laudanum, and he remained within doors, but continued to suffer. On the next day, the 16th, he took a cathartic. On the same evening, about 11 P.M., his wife was waked by finding him in a sort of convulsion; he then passed some fæces involuntarily, and was found to be unable to move or speak intelligently.

When seen the next day by his physician, he was found to have paralysis of motion and sensation in the left side, including the face. He was drowsy, but not comatose; he was made to understand who his physician was, but could not answer questions intelligently; he called for gin, and yet he was said to have been of temperate habits.

Pulse was slow and full. Within the next few days he regained his intelligence, so as to recognize every one, and to answer questions correctly, but not quickly, and he no longer made the irrelevant remarks which he had made at first. He was also able to move the left leg a very little when it was pinched, but this reaction did not subsequently increase. On November 24th there was crepitation and slight dulness, but no bronchial breathing or bronchophony in the lower part of the right lung before and behind. On November 25th, while being partly raised to take some milk, which was his chief diet, he suddenly complained of extreme pain in the lower part of the chest, to the right of the sternum. His face became congested and his whole body was bathed in profuse perspiration, and shortly his extremities, especially the right, non-paralyzed, became extremely cold. He was quite conscious, but complained of the pain, which, however, soon abated somewhat. The respiration was about 30 per minute, rather shallow, and accompanied by puffing out of the cheeks. The pulse was about 120 and very weak. Brandy was given him, and hot applications were made to the extremities. He rallied from the attack, and the pulse became stronger and less frequent, and he passed a good night.

On (3) November 28th, the night of December 10th, December 15th, and on December 20th, he had similar attacks, in the last of which he died suddenly. The pulse was quiet and weak during the attacks, but between them was remarkably slow, ranging from 48 to 68. During the last ten days of his life the pulse has been 90 and 100. The treatment consisted in giving brandy and laudanum. In one case morphine, administered hypodermically, had the happiest effect upon pulse, pain and respiration, and in a short space of time. He had very little other treatment—a little quinine, a little iodide of potassium, and a dose or two of castor-oil. The disease was held by his attending physicians to be one of multiple embolism—an opinion which Dr. Austin Flint, who was called in consultation, also gave.

Autopsy 24 hours post-mortem.

Body well nourished.

The *heart* was found to be a little enlarged. The valves were not very notably changed, though there were atheromatous deposits in both the aortic and mitral, the former being a little stiffened from atheromatous thickening. The aorta was also somewhat atheromatous. The left ventricle was considerably thickened.

The *right lung* was crepitant in front, but non-crepitant and adherent above and behind. There were some infarctions in the upper part of the lower lobe, varying in size from a small marble to a pigeon's egg. They varied in color from a yellowish-brown to a deep red.

The *left lung* was non-adherent, crepitant anteriorly, but congested hypostatically behind.

The *liver* and *spleen* presented nothing notably abnormal.

The *right kidney* was congested, somewhat lobulated, and cortex in parts adherent.

The *left kidney* was congested.

On exposing the *brain* the vessels of the meninges were distended with fluid blood, and there was considerable effusion of tolerably clear fluid in the meshes of the pia mater. The brain substance was soft and œdematous.

Upon the outer side of the right middle lobe a sense of fluctuation was given to the fingers as if there was a large collection of fluid in the middle lobe. When the brain was turned over on the left side, the wall of this softened middle lobe fell in for a distance of perhaps three inches in length and one to one and a half in breadth.

Examining the vessels at the base, they were, so far as could be seen, free from blood, but were markedly atheromatous at points. Following up the right fissure of Silvius, it was soon observed that the middle cerebral artery immediately beyond the origin of the ant. frontal, was tense from distention of the blood, and of a dull blue color; this distention extended onwards into the ant. and post. branches, one of which passes to the island of Reil, and the other to supply the middle lobe. From these points onwards they were empty, but the brain tissue about them was "mushy" in consistence, and of a faint reddish color. The softening also involved the floor of the corpus striatum of the same side, where the same condition of red softening could be seen. There were no marks of the ordinary vessels that are seen on the corpus striatum.

In this case the source of the emboli seemed to be the aortic valves, which were atheromatous, and minute masses might have been carried off from them and deposited in the brain and lungs. Microscopic examination of the plugs in the two branches of the middle cerebral showed that they contained granular matter and variously sized oil-globules, such as are seen in atheroma.

NEW YORK MEDICAL JOURNAL ASSOCIATION.

Stated Meeting. Feb. 4, 1876.

DR. E. G. LORING, PRESIDENT, IN THE CHAIR.

RECENT DISCOVERIES IN THE PHYSIOLOGY AND PATHOLOGY OF THE BRAIN.

DR. EUGENE DUPUY, in a plain and interesting manner, directed the attention of the Association to certain points relating to the function of different parts of the brain. His remarks were intended chiefly to overthrow the doctrine of localized functional centres, and were confined for the most part to the pathological lesions attending hemiplegia, hemi-anæsthesia, aphasia, and epilepsy. A review was made of cases from Charcot, Hitzig, Westfall's clinic, etc., and in these reports Dr. Dupuy believed he found just as much to disprove as to sustain the idea that there are in the brain localized centres for nerve force. Dr. Dupuy referred to the physiological experiments which have been performed upon animals with the view of locating such centres of nerve force; but he did not believe that they had substantiated the theory of localization. The doctor denies the excitability of the cortical substance of the brain. Aphasia may be developed by lesions independent of the island of Reil, or its immediate surroundings.

The natural fluid found in the cerebral substance and cavities constitutes one of the very best media for conducting electricity, hence must be removed as much as possible; absorbing with blotting paper is a good method, otherwise it will enter as a disturbing factor to the obtaining of exact results. When the experiments of Hitzig, Ferrier, and others have been re-

peated by Dr. Dupuy, after having taken such precaution as would enable him to apply the electrodes to a dry cortical substance, he has failed to verify the statements made by these experimenters. Dr. Dupuy's remarks were listened to with marked attention.

Dr. Dalton followed with remarks, in the course of which he referred to the fact that definite muscular contractions are produced in a living animal by the application of a very faint discharge of electricity to the cortical substance of the brain. Whether this is due to a physiological irritation conveyed downward, or is due to a simple diffusion of electricity to the deeper parts, is a question. The simplest explanation is, that the effect is produced by the conveying of a physiological irritation downwards. If it is due to a simple diffusion of electricity, why do we fail to get a certain set of contractions when the electrodes are applied elsewhere than over certain points? This fact was alluded to merely from its suggestive import, rather than because it carried with it any positive proof.

There are certain pathological lesions which are followed by certain clinical phenomena that are well established. For instance, when a patient has paralysis of motion upon one side it may be associated with lesions upon the same side or opposite side of the brain, but in by far the greater majority of cases upon the opposite. Now, when hemiplegia occurs from lesions upon the opposite side of the brain, it is due to a well-known anatomical reason; and when it occurs from a lesion upon the same side of the brain, there is doubtless an anatomical reason, the same as in the other instance, except that it has not yet been found. The subject is full of interest, and requires carefully conducted experiments to settle certain perplexing questions arising both in physiology and pathology.

Dr. Dupuy remarked with regard to the impression being conducted downward into or through the corpus striatum, that he had divided all the fibres going to that body, breaking it up entirely, and obtained the same muscular contractions as when the corpus striatum remained intact.

The hour of ten having arrived, the Association was adjourned.

Correspondence.

HÆMOPTYSIS: RELATION TO BAROMETRIC PRESSURE.

To the Editor of The Medical Record.

Sir:—The following case may be of interest to some of your readers:

May 25, I was called to see Mr. Q., aged 21 years, who had a violent attack of hæmoptysis, the first with which he had ever been visited. He is a gentleman of fine physical development, and has always enjoyed good health. His father died of consumption, but neither he nor his brother or sister—all of whom are grown—has manifested any symptoms of the disease before the attack in question. He has always taken more than the ordinary amount of physical exercise, using dumb-bells, Indian clubs, etc. These last he used during the summer of 1874, and he resumed their use in the spring of this year. He had not gone through his usual evolutions with them on the day of his attack, but had exercised with them somewhat violently the day previous. The day of the attack he felt as well as usual, was quietly engaged during the morning, and about the middle of the day lay down on his bed. Shortly after the hemorrhage came on suddenly, and was very profuse, occurring in the lower lobe of the left lung. Mr. Q. has had no hemorrhage since this attack.

The point of interest to which I wish to invite attention is this—*the coincidence of the hemorrhage with the time of minimum barometric pressure during a period of several days preceding and following the attack, this coincidence extending not only to the day of the month, but also to the time of day.*

Knowing that the month of May had been one of exceptionally low atmospheric pressure, I concluded to investigate the subject more accurately. I therefore, some days afterward, obtained from Prof. F., who keeps the meteorological record at this station for the War Department, the readings of the barometer for several days before and after the 25th of May, and here append them. These observations were taken thrice daily at 7 A.M., 2 P.M., and 9 P.M. I also give the average of each day's readings:

May 18	29.269, 29.165, 29.105	= Average	29.180	May 24	28.850, 28.767, 28.812	= Average	28.810
" 19	29.118, 29.047, 29.010	= "	29.058	" 25	28.824, 28.759, 28.777	= "	28.787
" 20	29.089, 29.047, 29.160	= "	29.099	" 26	23.992, 28.875, 28.897	= "	28.921
" 21	29.032, 28.957, 28.947	= "	28.979	" 27	28.962, 29.166, 28.852	= "	28.973
" 22	28.911, 28.928, 28.935	= "	28.925	" 28	29.011, 29.001, 28.962	= "	28.991
" 23	28.909, 28.824, 28.860	= "	28.864	" 29	29.076, 29.051, 29.073	= "	29.067

I could have gone back of May 18, and shown that the mercury had descended almost from the beginning of the month, and it continued to rise even after the 29th.

This may be simply a fortuitous coincidence, but I can hardly resist the belief in a causative relation of greater or less degree between the two events. I am inclined to think that the increased arterial tension caused by diminished barometric pressure, superadded to the strain of the previous day's exercise, precipitated the catastrophe, which might otherwise have been escaped. We are all familiar with accounts of such hemorrhages occurring in ascending mountains, although some observers are disposed to attribute them to the unaccustomed exertion rather than to rarefied atmosphere. This explanation, however, would not suffice in the case of aeronauts.

I report the case that the question may be tested by other observers.

Alfred B. Nelson, M.D.

Danville, Ky., *Feb.* 6, 1875.

Children's Hospital of the District of Columbia.—The fifth annual report of this institution states that the aggregate number of patients treated during the past year was over 1,700, an increase of 700 over the previous year. The charity is in a prosperous condition generally, and is constantly increasing its usefulness. The medical staff consists as follows: Consulting Medical Board—Drs. J. C. Hall, Grafton Tyler, C. H. Leebermann, W. P. Johnston, and Johnson Eliot: Attending Physicians—Drs. F. A. Ashford, S. C. Busey, W. B. Drinkard and W. W. Johnston: House Physician—W. W. Streeter, M.D.

SIAMESE OBSTETRICS.

To the Editor of The Medical Record.

Dear Sir:—Thinking a short article on Siamese Obstetrics might be interesting to your readers, I forward you the following description of practice in this country, from my own observation. When a woman is about being confined, several female friends are called in as attendants, also the old "yi" or midwife. Another name they have for her is moh-rasksah-cran.

The only means they have for aiding the woman in labor are manipulations and pressure. They place the patient on her back, then a woman is seated on each side, these two women begin by forcibly pressing the abdomen down and backward.

This procedure is continued from three to five hours; then, if having failed to expel the fœtus, one of the attendants is supported by the hand while she tramps the abdomen of the patient; always placing her feet above the fœtus. Then, as a *dernier ressort*, all other means having failed, they suspend the *parturient* by means of a band beneath the arms. One, and sometime two, of the attendants, will then clasp with their arms the body of the patient and suspend themselves also. This last expedient seldom fails to produce a rupture in some direction,—it may be the uterus, perinæum or encephalon of the child. I am certain many children die from harsh treatment during parturition.

I have seen even adults with cysts of large size attached to a point corresponding with the anterior fontanel of infancy, and heads of the still-born dreadfully lacerated. W. L. Hutchinson, M.D.

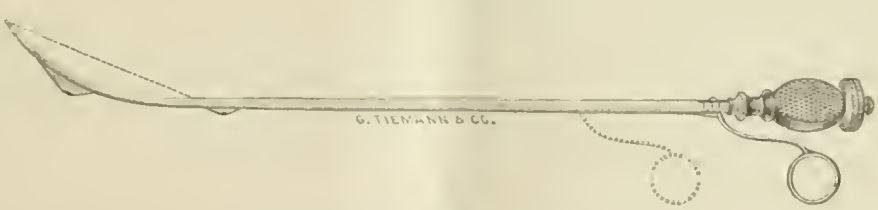
Bangkok, Siam, *November* 11, 1875.

New Instruments.

A DILATING URETHROTOME.

By JAS. ANDREW MILNE, M.D.

In offering a new stricture instrument to the profession, it is not that I would ignore the many valuable ones already brought to notice and repute; but believing the one here represented to meet many requirements not fulfilled by others, I cannot but feel certain it will be appreciated by those that employ it.



The instrument consists of a dilator that is brought into action by a screw force at the handle, producing traction upon a flexible rod attached to the terminal extremity of the instrument, and is lifted from a curve to bridge over the concavity, making it a dilator of capacity and power.

Near the handle, upon the side, is a graduated scale, showing at a glance the exact degree to which the dilator has been opened.

Upon the convex side of the instrument slides a guarded knife for dividing the stricture tissue.

The point is so constructed that a small whalebone bougie can be attached, to serve as a guide in cases of very small calibre; thus a stricture of slight capacity can be permeated.

The size of the instrument when closed is No. 8 French; therefore it is much smaller than any other instrument I am acquainted with—even Dr. P. H. Watson's modification of Mr. Holt's dilator, which is 10 French. This great reduction in size does away with much of the trouble of dilating a stricture with bougies so as to admit of the use of any of the instruments heretofore in use.

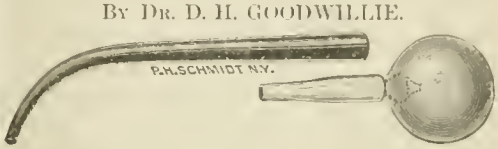
I have used the instrument in a sufficient number of cases to test its working fully, and am certain it will find favor with those that employ it.

Internal urethrotomy is the most reliable, by far the safest, more readily accomplished, and the most effectual means of cure for stricture of the urethra yet devised. A careful and thorough division of the tissue forming the stricture, followed by the use of a sound of *large size*, until the work of healing has been perfectly accomplished, can but result in the most satisfactory manner.

Oswego, N. Y., *Jan.* 10, 1876.

IMPROVED LARYNGEAL INSUFFLATOR.

By Dr. D. H. GOODWILLIE.



The above cut represents a laryngeal and post-nasal insufflator. It consists of a stem of hard rubber, and a glass powder-holder attached to a ball of soft rubber. The powder-holder fits into the stem. The advantages are, that it is easily loaded by putting the glass-holder into the powder in the bottle. The powder fills up the whole calibre of the tube, and so is sure to be blown out. The glass-holder can be readily disjointed from the ball, and, by tubing, be attached to the air-receiver if desired. Use a bottle for your powder two inches deep, with a wide mouth. Keep the ball and holder in the bottle when not in use, instead of a cork, and it will be always ready loaded for use when wanted.

160 West 34th Street.

CHANGES IN THE PUBLIC SERVICE.

ARMY.

Hubbard, Van Buren, Assistant Surgeon.—Granted leave of absence for two months. S. O. 26, A. G. O., Feb. 7th, 1876.

The Concours for Forty-seven Appointments of House Surgeon to the Paris Hospitals has just ended, and the examination is said to have been very creditable to the proficiency of the candidates.

Medical Items and News.

Death of Dr. E. Lee Jones.—We are pained to hear of the sudden death, on Jan. 30, 1876, at Oakland, Cal., of our esteemed friend Dr. E. Lee Jones, for a long time an honored and influential practitioner of this city, and an active worker in many of our societies. Two or three years since, in consequence of failing health, he took up his residence in Oakland, where he was honored by his medical brethren in many ways, not the least of which was his election as President of the Alameda County Medical Association. The following action was taken by that body regarding his death:—

Oakland, Cal., *January* 31, 1876.

At a special meeting of the "Alameda County Medical Association," held at its rooms this evening, a Committee was appointed to draft resolutions regarding the death of the late Dr. E. Lee Jones, consisting of Drs. Wm. P. Gibbons, Jno. C. Van Wyck, and Chas. S. Kittredge, who presented the following:

Whereas, The presence of death, at all times sorrowful, has been especially so in a recent visitation, which has removed Dr. E. Lee Jones, President of this Society, from an honorable and useful career among men; therefore,

Resolved, That in the life and daily walks of the deceased we recognize a character which combined purity of life, integrity of principle and high intellectual culture with a professional life, and made up the substance of a true physician.

Resolved, That we desire so to emulate his standard virtues, that while we honor our profession before men, we may ultimately receive the benefaction now realized by our deceased brother, and which is promised to good and faithful stewards.

Resolved, That our sympathies follow his bereaved family through the cloud of sorrow which now rests about their habitation.

C. S. Kittredge, M.D., *Secretary*.

Snow in the Streets.—When snow falls in the streets of Lyons (France), it is immediately washed away by hose attached to the water mains. Not only is the snow thus disposed of, but the streets are washed clean.

The Medico-Legal Society is founding a library. A large number of very valuable works have been secured, among them a complete set of the *Annales d'Hygiène Publique et de Medecine Légale*, numbering ninety-two volumes. The late President, Mr. Clark Bell, has been untiring in his exertions to give the library a good start, and to his special labors and contributions is in most part due its promising future.

Medical Testimonials.—The practice of giving medical testimonials in favor of articles of commerce is on the increase in London. "A very common device," says *The Lancet*, "is to send the medical man some of the article it is designed to puff. He incautiously acknowledges receipt, with a few graceful remarks, the product of ordinary civility, and straightway his name appears in print." We have the same trouble here, but in a more aggravated form.

Dr. Tilt, of London, has been elected honorary fellow of the Obstetrical Society of Philadelphia.

Scrofulide.—"The Treatment of the Different Forms of Scrofulide" is the title of a pamphlet by Dr. H. G. Piffard of this city, which is republished from the *London Practitioner*.

The Children's Hospital of Boston treated during the past year one hundred and forty-five patients, of whom sixty-nine were cured, twenty-three relieved, and sixteen died. In connection with the institution, a convalescent home has been established fourteen miles from Boston, a short distance from the station in Wellesley. From the first of June to the middle of October thirty-nine children were treated there. The experiment is said to be a success.

Decay of Trees in Kensington Gardens.—There is considerable anxiety manifested in regard to the probable decay of many of the finest trees in these famous gardens. Many causes have been assigned, the most reasonable of which are, the absence of the natural mould at the foot of the trees, too perfect drainage of the soil, and the deteriorated air of London.

The New Medical Staff Bill introduced by Senator Logan is making good progress, and there is a reasonable hope of its becoming a law.

Trenton Lunatic Asylum.—A legislative committee has been appointed to inquire into alleged extravagance in the management of this institution.

United States Medical Directory.—A second revised edition of this work is to be prepared.

New York Veterinary Society.—The following officers have been elected for the ensuing year: A. Lockhart, M.R.C.V.S.L., President; J. L. Robertson, M.D., V.S., Vice-President; J. D. Hopkins, V.S., Treasurer; and L. T. Bell, V.S., Secretary.

Bronchocele in Horses.—Prof. Liautard, of the American Veterinary College of this city, recently successfully extirpated two large bronchocele from horses, aged respectively nine and fifteen years. With one exception, no similar cases have been reported for the past thirty-three years.

Vivisection.—The discussion of this subject, which has been carried on so extensively in England, has been referred by the Government to a Royal Commission, from which a report is soon expected.

An Asylum for Lepers at Bombay, with a capacity for 150 patients, is to be built as a memorial of the visit of the Prince of Wales.

The New York Dermatological Society has recently adopted the rule, that candidates for admission shall apply in writing to the President, and accompany their application with an appropriate thesis. This is an evidence of progress.

The Plague is said to have reappeared in Mesopotamia.

Death from Chloral.—Another death from an overdose of Chloral is reported in the *Medical Press and Circular* (January 19). The patient was a lady, who took of a patented preparation a quantity which was ascertained to contain one hundred and twenty-five grains of the drug.

A VARIETY OF "INFANTILE HERNIA," STRANGULATED, WITH OPERATION.

By JAS. D. TRASK, M.D.,

ASTORIA, N. Y.

FRIDAY, Jan. 7th, of the present year, I was called in haste at 9 P.M. to a gentleman, a stranger to me, in relation to whom I learned the following history:

Mr. E. P., æt. 57 years, on rising Wednesday morning, Jan. 5th, went to the well to draw water. In the act of lifting the pail, he was conscious of an unusual sensation in the left groin. At least twelve years ago Mr. P. was the subject of hernia in the same spot, and wore a truss; but for the last six years he had not worn the instrument, neither, as he believed, had the gut come down during that time. On the recurrence of the hernia he went to bed, suffering from discomfort in his bowels, not at first recognizing the hernia, and took an ounce of castor-oil. The oil was almost immediately vomited, and the dose was repeated. The second dose having been rejected, he took repeated draughts of saline cathartics, all of which were thrown from the stomach, and no action of the bowels took place. He had also taken a warm bath. Suffering from pain in the bowels, the stomach rejecting all nourishment as well as medicines, he passed the whole of Wednesday, Thursday, and Friday in great distress, but obstinately refusing medical aid.

In the evening of Friday he allowed a physician to be sent for, who administered a large dose of morphine hypodermically, and retired from attendance.

When seen by me two hours afterward, the patient was in a state of collapse. The pupils were contracted from the morphine, but he still complained of pain at the seat of the hernia. The intellect was perfectly clear; he gave a history of his case, and stated that the matters vomited during the day had been observed by himself to have a distinctly fecal odor.

At first glance it seemed to me that he was beyond reach of aid. On inquiry, however, I found that he had as yet taken no stimulus. On giving him brandy, and applying heat to the extremities, a portion of the brandy was retained, and some reaction ensued.

On examining the tumor it was found to be about one and a half inches in its long diameter, and one inch in its transverse, and it occupied the ordinary site of femoral hernia. Considerable doubt was felt as to the character of the hernia, whether inguinal or femoral. After quite a protracted examination by myself and a medical friend who, with my son, was assisting me, there seemed to be little reason for regarding it as anything else than femoral, and yet this could not be determined with confidence. It lay almost altogether below Poupart's ligament, and the finger could readily be passed in the direction of the femoral vessels. The pubes having been shaved, a short neck could be felt upon deep pressure, extending to the site of the internal abdominal ring. Gentle taxis was unsuccessful in reducing the tumor.

In consequence of the extreme prostration of the patient he was not etherized. An incision was made through the integuments, from over the internal ring downward and slightly inward, in the direction of the femoral ring, and in the long axis of the tumor. Beneath the integuments the dissection was made by the knife through a layer of condensed connective and fibrous tissue, which could not be taken up by the director. Beneath this the director was employed, and by its aid two pretty distinct planes of muscular fibres were divided, as well as some loose areolar tissue beneath these, exposing what was regarded as the hernial sac. This structure was raised by the forceps, and when snipped, divided upon the director. The interior of a serous sac was thus exposed, and what was assumed to be the knuckle of intestine came into view. The finger could be passed in freely upon the pubic side, and swept downward, encountering several small thread-like bands, most of which were broken by the finger, and some cut by the knife. The tumor could be turned out of its investing sac, and seemed quite movable, but the bands high up on the under side, and also on iliac side, were found too numerous and dense to be broken up. Carrying the finger up toward the internal ring, the neck of the tumor was found adherent to it on all sides. It was impossible to pass the director or probe at any point. At this time we knew only of the recent strangulation, but had no positive knowledge as to the past condition of the hernia; and it was by no means improbable that a portion of the gut had been down for years, and contracted adhesions. The knuckle had the glistening aspect of intestine, and after awhile lost its lustre from exposure to the air. On pinching up a portion of the wall, for it was not tense, this could be distinctly detached from a mass within, which had the feel of omentum. If the knuckle were intestine, the contents were inexplicable.

An attempt was made to dissect up the supposed adhesions by the sharp finger-nail. By this means the internal ring seemed to have been opened up in front, and enlarged to receive the tip of the finger. Taxis was tried, but failed to reduce the swelling. It was now discovered that the finger had dissected up a plane of fibrous tissue. After introducing the director beneath fasciculi of the supposed adhesions of the neck, these were divided. This was repeated again and again, until the director at last penetrated a cavity, and being turned downward and forward, could be passed onward so as to be felt beneath the investing wall above referred to; and this being laid open by the knife, the intestine itself came into view.

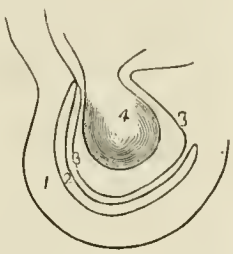
Notwithstanding the duration of the strangulation and the gravity of the symptoms, the intestine appeared to be in a condition to justify its return. It was flaccid and entirely empty. On carrying the finger up to the internal ring, by a little exertion this was enlarged so as to allow of the reduction of the intestine. The lacerations that had been effected outside the neck of the sac proper, rendered the opening into the peritoneal cavity so large that the intestine could not be kept reduced. In consequence of this I introduced two silver sutures through all the investing structures and the peritoneum, and closed the wound. Not a drop of fluid was found in either sac.

The operation, necessarily somewhat protracted, was borne with scarce a complaint, and the patient expressed himself much relieved after return of the bowel. There was no more hiccup; and food and stimulants were retained. He sank, twelve hours after the operation, from the exhaustion of prolonged and unmitigated suffering and want of support.

What were the nature and origin of the false sac first encountered? It was clearly peritoneal, and the hernia a form of the variety improperly called "infantile." As described by Gray (see *Anatomy*, Amer. edit., 1870, p. 829), in infantile hernia "the hernial sac descends along the inguinal canal *into the scrotum*, behind the pouch of peritoneum which accompanies

the cord and testis. The abdominal aperture of this pouch is closed, but the portion contained in the inguinal canal remains unobliterated." The hernial sac is invested more or less completely by the posterior layer of the tunica vaginalis, with some areolar tissue between, "so that in operating upon this variety of hernia, three layers of peritoneum would require division."

The only explanation that can be offered of the conditions found in the case now reported, seems to be, that adhesions of the opposite surfaces of the tunica vaginalis had occurred not only at the abdominal ring, but from the testis upward, quite into the inguinal canal, but not throughout its entire length, leaving a space in the upper portion of the canal still open. The knuckle, originally passing through the internal ring, descended a very little distance behind this closed sac or pouch of peritoneum, sufficiently far to engage it so as to carry the pouch before it as it itself advanced in its course forward. The mechanism of this will be easily understood from the accompanying diagram.



Had it been a case in which the tunica vaginalis was yet open at the abdominal ring, but closed from below upward, it would have been simply a modification of ordinary congenital hernia, and there would have been but one peritoneal covering. The adhesions that were broken up by the finger nail during the operation were those by which the abdominal opening of the tunica vaginalis had been originally obliterated. By the destruction of these adhesions outside the true sac, the finger had gained access to the peritoneal cavity.

The hernia apparently occupied but a small portion of the inguinal canal. It certainly did not follow the course of the canal; but emerging from the internal ring it passed first directly forward, and then downward, over and below Poupart's ligament, so as to lie directly upon the saphenous opening. Hence the difficulty in diagnosis. The ordinary coverings of such a hernia would be integuments, superficial fascia, tendon of external oblique and internal oblique muscle, which latter furnished muscular fibres that were encountered in the operation. Beneath these would come the two layers of tunica vaginalis, and under these the hernial sac itself. In the present instance the protrusion unquestionably occurred through a fissure in the aponeurosis of the external oblique, as no layer corresponding to this was encountered in the operation. Occupying this position, the possibility of its connection with the tunica vaginalis could hardly suggest itself.

All authors concur in the rarity of what is called infantile hernia. Mr. Birkett, in Holmes's System of Surgery, describes four different conditions in which the infundibuliform process of the tunica vaginalis may be found after descent of the testis, but neither of these corresponds to that here described.

After examination of the principal surgical authorities, I can find no account of the occurrence of hernia under the peculiar conditions met with in the case here reported, and I am therefore inclined to believe that it is a form heretofore undescribed.

A NEW UTERINE APPLICATOR.

By JOSEPH R. BECK, M.D.,

FORT WAYNE, INDIANA.

(Read before the Allen Co. (Ind.) Medical Society, Jan. 4, 1876.)

THERE can no longer be any doubt entertained by any practitioner who has carefully noted the progress of events, of the fact that the injection of a medicated fluid into the cavity of the uterus is hazardous. Perhaps it would be as well, while we are engaged in classifying the operation, to follow in the wake of the insurance men, and denominate it an "extra-hazardous" operation.

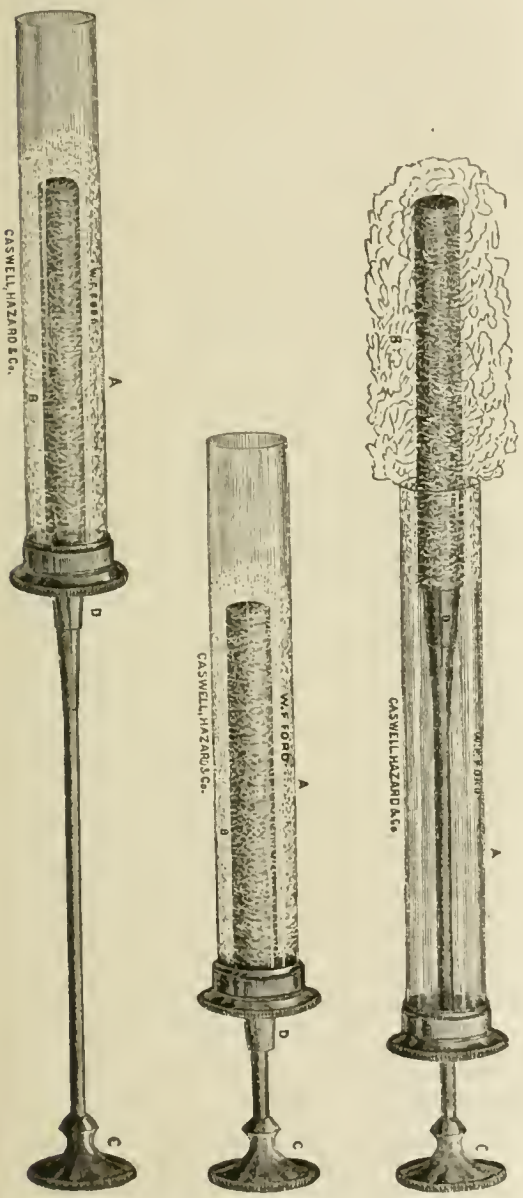
The echoes of the fierce discussion which was had on the propriety of this procedure, having a special bearing on the employment of the perchloride of iron in post-partum hemorrhages, have scarcely ceased to reverberate through the hall of the British Obstetrical Society, where the operation was bitterly assailed, and as carefully defended, ere the busy practitioner, who had accepted the legitimacy of the operation, because of the undoubted authority which stood as its sponsor, began to record his experience in its employment. It is a peculiar fact, and one worthy of a passing notice at least, that although Dr. Barnes advocated the operation because of its great success in his hands, yet probably not more than a dozen other practitioners, who followed him in its use, are able to add very powerful testimony to its unvarying good results. On the other hand, scarcely a week passes in which death, as the result of this operation, is not recorded somewhere.

I do not propose to insinuate here that the *application* of fluid medicaments to the intra-uterine mucous membrane is improper or illegitimate. On the contrary, the measure counts among its advocates none warmer in its praise than myself, particularly in the application of the perchloride of iron to a post-partum hemorrhage. But——! This exclamation implies an objection, and the objection exists in the fact that while I am an enthusiastic advocate of the *application* of such medicaments, yet I am no less earnestly opposed to their application *by injection*. Take, for example, the history of post-partum hemorrhages, where the principal object has been to restrain the flow. The mechanical part of the operation has almost uniformly been a success; but the case has thereafter so very frequently resulted in a "smart peritonitis," or—death, that we may well begin to suspect that there is something in the matter which is radically wrong.

It cannot be that the wrong lies in the medicine, and hence I apprehend that the whole burden of the trouble may justly be cast upon the manner in which the remedy *has been applied*. Of course, as I am an advocate of the employment of intra-uterine medication in hemorrhages and otherwise, no discussion of its merits need be touched upon in this paper, and the point to be insisted upon, succinctly stated, is only as follows:

The application of a solution of the perchloride of iron will always check a uterine hemorrhage, except in occasional cases of very large fibroids, or cancerous elaborations; but the *injection* of the medicine will occasionally and semi-occasionally produce death in

addition to a checking of the hemorrhage. This is an unfortunate state of affairs, and the more so in that the number of fatal terminations is understated rather than exaggerated. If it were deemed necessary, a number of my colleagues in my own State could testify to the correctness of this observation. Some of these gentlemen were expert gynæcologists, too, as I happen to know, and were fully provided with the most improved apparatus for injection, and yet they are compelled to report that death frequently lurks in the operation.



[Instrument closed. *A*, Barrel; *B*, brush-plunger; *C*, concealed piston; *D*, point where *C* fastens into *B* when ready for use.

C withdrawn from plunger and caught at *D*. Ready for use.

C returned into *A*, extrudes the brush-plunger *B* into the uterine cavity. It has been previously charged with the medicament, and by turning *C* in the barrel *A*, the plunger is made to revolve, and thus touch the whole intra-uterine surface.]

This brings me to what I desire to present as my own views in the matter, and to explain what I have devised and substituted in the way of *application* for *injection*.

In the summer of 1871 I was called to see a married woman, living about five miles south of the city, who had been an invalid for about two and a half years. She had never fully recovered from her last labor, which had occurred about that length of time prior to my visit, and the trouble had originated in all probability from a remnant of placenta having been allowed to remain in the uterus after delivery. It is needless to go into the details of the treatment I gave her, and it is sufficient to remark that after dilating the cervical canal, and scraping off the adventitious growth, the patient had a terrific hemorrhage. This I eventually succeeded in checking by means of the injection of the perchloride of iron solution, carried in through an excellent double catheter. The patient had pelvi-peritonitis rapidly developed, and in spite of all efforts died inside of two weeks.

I had employed various other plans of treatment unsuccessfully, before resorting to the iron injection, and my mind is fully made up that the *injection*, not the medicine, was the exciting cause of the peritonitis, and hence of the death. I can contribute much testimony as to the value of the remedy, and feel satisfied that its field of usefulness should be more widely extended; but my voice has been from the time of this death totally against the *injection* of *any* medicament into the cavity of the uterus, *under any circumstances*, on account of the great danger incurred thereby. My opposition to the measure is still more decided since I know that the same good effects attending the *injection* may be attained by other means, which, in addition to being equally effective, have the qualification of being absolutely and entirely devoid of any danger.

I had about the time referred to, numerous cases of hemorrhage following abortions and miscarriages, and occasionally a few after labor at term, and the question forced itself upon me as to how the iron solution could be *safely* applied to the uterine mucous membrane, when other well-known remedies had failed to arrest the hemorrhage. It had also been a matter of frequent note with me, that the various instruments designed for the application of remedies to that membrane in other diseases were, in many instances, lamentable failures (notably the application of iodine for chronic endometritis); and quite a long time ago, as early as the winter of 1871, in fact, I thought of devising some means whereby the necessary applications could be made to this membrane, *with absolutely no danger*, and with the production of less uterine colic than was the case generally. Revolving the matter in my mind, I finally designed an instrument for this purpose, which I denominate my "Uterine Applicator," and to which I desire to call the attention of the profession. In my humble judgment it is, for its purposes, as nearly perfection as it is possible to have any instrument.

The description of the Applicator will occupy us but for a moment, owing to the fact that there is so very little to describe. It consists of three parts, a barrel, a brush plunger, and a concealed piston. It is so simple that its every qualification can be easily seen in the subjoined figures. The barrel is made of glass,

and is three-quarters of an inch in diameter, and six inches long. The plunger and piston are of brass, nickel-plated, the former being four and a half, and the latter six inches long, thus giving an extreme length of ten and a half inches, which I have found to be long enough to meet every indication. The plunger is covered with a brush made of a piece of sheepskin, with the wool on, which is put on the plunger while the tanned skin is wet, and thus hugs the plunger tightly when it dries. The figures explain the instrument in other particulars.

It will be seen from the description of the instrument that its range of usefulness can be almost indefinitely extended, and that every case which requires an application of any medicine to the cavity of the uterus, can be fully and completely covered by my Applicator, so long as the medicament used is either in a liquid or a pulverulent form. It is, of course, entirely unnecessary to detail the pathological conditions in which the instrument affords an invaluable aid, and it is sufficient to say that in a series of the most severe and exhaustive trials, covering a period of four years, I have never had one occasion to be dissatisfied with it.

It is manufactured solely by Mr. W. F. Ford, of New York, and is also for sale by Messrs. Caswell, Hazard & Co., of that city. The great simplicity of the instrument implies a corresponding cheapness in cost, and the result is that every practitioner can add one to his obstetrical case, with no inconvenience to himself. The brush, if carefully cleaned after using, will remain in good condition for a long time, and the remaining portions of the Applicator will never wear out.

With the remark that the instrument is only intended to be used through a dilated os and cervix (which reminder is, however, not needed), when applied to the uterine cavity, I invite the profession to a consideration of its many manifest merits.

15 East Washington Street.

A CASE OF PUDENDAL HEMORRHAGE.

By HENRY N. READ, M.D.,

ADJUNCT PHYSICIAN TO THE LONG ISLAND COLLEGE HOSPITAL.

Mrs. S——, a delicate, nervous woman, engaged me to attend her in her fifth confinement, which, as she menstruated last in the second week in December, 1874, I entered on my record as due the middle of September. I was called in several times during the month of July to prescribe for her, and found her always suffering from weakness, fainting spells, and pain in the lower limbs and feet; the veins in the legs were greatly enlarged, and considerable œdema also existed; no albumen in urine. Enjoining rest in a horizontal posture and the avoidance of all exertion, I had not seen her for a week when I was sent for, the evening of the 10th August, in great haste, with the intelligence that she was in labor and flooding. When I arrived at her house I found her in bed, perfectly exsanguinated, with an anxious countenance, complaining of a burning pain in the vulva, but no labor pains. The nurse told me that "it did not act like a labor case;" that the patient had lifted one of her children from the floor, and had immediately sunk down saying, "that something had given way." When she was carried to bed a pool of blood was found on the floor, which continued to run very fast as she was carried along. I passed my hand under the clothes and found a tumor between the thighs, and on inspection found the bed saturated with blood of a dark venous kind, which was issuing with a perfect gush, from an opening in the inner side, through the mucous membrane of the left labium majus. The left labium itself was enormously enlarged, fully equal in size to the head of a new-born child, of a color almost black, and exquisitely painful to the touch. The opening through the mucous membrane readily admitted two fingers and thumb, and was situated within the vulva, which made it more difficult to reach; great tension of the parts also existed, with great pain to the patient on touching. The right labium was, with all the external genitalia, completely hidden, and the tumor, as the patient lay with limbs extended, looked like a large blue-black bag, occupying the whole of the space between the thighs. I immediately passed my fingers into the opening and turned out a quantity of clots, but this was followed by a gush of blood, which quickly filled up the cavity occupied by the clots, and ran in a stream from the opening. I then hastily stuffed into the opening rags dipped in ice-water, pushing in as many as possible, and, keeping my fingers pressed on them, sent for persulph. of iron, in the meantime stimulating with whiskey and ammonia. When the persulph. arrived I saturated a number of pledgets of raw cotton with it, and then removing the rags and clots rapidly filled up the space with the pledgets. This checked the hemorrhage somewhat, but it soon began again, and I again emptied the cavity of the pledgets, and taking the bottle thrust the neck into the opening and poured about ℥ ss of the solution into the cavity; fresh cotton was then packed in, and this controlled the bleeding effectually. The patient complaining of intolerable burning pain, I gave half a grain of morphine, and having bandaged the legs from the feet up I made her comfortable. No hemorrhage returning, after waiting some time I left at 10½ P.M. Returned at 2 A.M., found no bleeding; patient complaining and restless. At 10 A.M. next day no hemorrhage, patient very restless, suffering great pain; temp. 102½°, pulse 130. The tumor appeared hot, hard, and very tender, with no diminution in size. I drew the water with difficulty, owing to the swelling, and this gave much relief. Fearing lest inflammation and septicæmia should set in, I made an attempt to remove the material in the tumor, but the first attempt caused bleeding, and it was abandoned. Gr. ⅛ morph. was ordered every two hours, and iced cloths applied to the tumor. Saw her at 5 P.M. same day; temp. 103½°, pulse 140; no reduction in size of tumor, but less heat and tenderness; patient more quiet and somewhat under influence of morph. Ord. gr. iij. quin. sulph. every three hours, iced cloths continued; morph. stopped. Saw her at 10 A.M. next day; temp. 102°, pulse 124. No change in condition of tumor. Complaining of severe intermittent pains in back, resembling labor pains. Alarmed lest labor should set in with such an obstacle in the way of delivery, I again attempted to remove the packing, but the hemorrhage again appearing I had to desist. The quinia was stopped, and gr. ¼ morph. administered, and I had the satisfaction of finding the pains in the back cease; continued iced cloths, and administered nutritious food and whiskey. No change at 6 P.M. same day. At 10 A.M. next day, third after the accident, I found a decided improvement; temp. 100½°, pulse 110. Tumor somewhat shrunken, with slight oozing, and very offensive smell. Beginning carefully I removed piece by piece the contents of the tumor. A large cavity was left, which was injected with a solution of carbolic acid, and injections ordered every two hours, as there was a large and offensive discharge.

The patient progressed favorably from this time, and at the present writing is walking about the house. The labium is shrunken to its normal size, and no deformity of parts exists; the varicose veins and œdema of lower legs have also disappeared. The case presents some interesting points. The occurrence of this accident is much more common during parturition, or just after it, than previous to it. Simple thrombus of the vulva, with no external opening, is neither during pregnancy nor parturition a dangerous affair; but with a large opening, or with any opening externally communicating with the engorged plexus of veins of the bulbi vestibuli, it cannot but be regarded as very serious. The only other case that has come under my observation—one in the practice of a friend—terminated fatally before medical aid could be obtained, hemorrhage being the cause of death. Authors differ as to the prognosis of the accident. Velpeau regards it as rather belonging to the non-pregnant than to the pregnant woman, and states that it is *not dangerous*, owing to the fact that there are no large vessels in the vicinity to be injured. This evidently refers to thrombus in the unimpregnated woman, for enlargement of all the vessels in the parts adjacent to the organs of generation takes place to such an extent in the latter months of pregnancy that we get the vaginal pulse distinctly by a finger in the vagina, and any rupture of a vessel in these highly engorged parts, where the veins and plexuses communicate so freely, must be regarded as serious. Cazeaux gives the prognosis as unfavorable, citing the statistics of Deneaux, who collected sixty cases, occurring before, during, and after parturition, in which there were twenty-two deaths—36.6 per cent. Perret and Blot also state the prognosis very grave. Prof. Barker gives the prognosis as much more favorable than the French authors cited, and thinks that improved methods of diagnosis and treatment account for it; in his admirable work on "Puerperal Diseases" he cites thirteen cases which had occurred at Bellevue Hospital during his connection with the institution, in which there were only two deaths. Scanzoni has collated fifteen cases, with no death. A case of Wood's, and one of Sayre's, with recovery in each, is mentioned by Barker. The very different views of men equally eminent may, I think, be explained on a different ground from that advanced by Barker, viz., "improved methods of diagnosis and treatment." The diagnosis of these tumors is readily made, a simple inspection being sufficient; and as far as regards the treatment, all authors to whom I have referred give the treatment as the same—Barker himself, Cazeaux, Thomas, Scanzoni, Deneaux, Velpeau, Bedford, Tyler Smith, and others. My theory is, that the prognosis depends very much on the anatomical point of rupture of the blood-vessel. If this take place superficially, *i.e.*, between the skin and superficial aponeurosis, or between the superficial and middle aponeuroses, the prognosis is favorable; but if it occur between the perineal and pelvic aponeuroses, or above this latter, the prognosis is obviously very grave; for in either of these cases, the blood following the reflections of the aponeuroses, could invade the entire pelvis, extending even to the iliac fossæ and peritoneum, and if the hemorrhage could be controlled, fatal peritonitis would be most likely to occur. In my case the rupture occurred between the superficial and middle fasciæ, and the blood was necessarily confined to the cellular tissue of the labium, so when the external opening was closed hydrostatic pressure caused the bleeding to cease.

I was sent for to attend Mrs S——, on the evening of the 23d of Sept., and after a five hours' labor she was delived of a female child weighing about seven pounds. The breech presented, but nothing unusual occurred during labor, the child being born alive, though feeble, and for a few days it was doubtful whether it would live; it soon began, however, to thrive, and both mother and child now enjoy excellent health.

549 Henry Street, Brooklyn.

Progress of Medical Science.

Abdominal Section for Intussusception.—At a recent meeting of the Royal Medical and Chirurgical Society, three papers were read upon this operation. Mr. Howard Marsh related a successful operation, performed by himself on an infant seven months old, that had been complaining for thirteen days. The bowel was found projecting two inches beyond the anus, and the ileo-cæcal valve could be seen at the extremity of the protrusion, while in the abdomen a firm cylindrical tumor was felt. Insufflation, and the careful distention of the large intestine with lukewarm water, failed to reduce the intussusception. Abdominal section was then decided upon. Chloroform having been administered, the abdomen was opened to the extent of two inches in the median line, just below the umbilicus. It was impossible to reduce the intussusception by the introduction of two fingers into the abdomen, so the bowel was first withdrawn from the abdominal cavity, and then reduction was easily effected. At least one-half of the colon and an equal part of the small intestine were invaginated. The intestine was returned into the abdomen, and the wound closed with hare-lip pins and superficial sutures. No bad symptoms followed. Sickness ceased at once after the operation, flatus was passed on the second day, feculent matter on the third, and on the fourth the child was convalescent. Mr. Marsh thought that in this case the intestine was merely invaginated for thirteen days, and that inflammation set in twelve or fourteen hours before the operation. He concluded by referring to the necessity of undertaking the operation, if all other means had failed: first, in acute cases of not more than twelve or fourteen hours' duration; and, second, in chronic cases in which there had been no symptom of inflammation or strangulation of the intestine. The second case was under the care of Dr. Hilton Fagge and Mr. H. G. Howse. This case, an adult with intussusception, without symptoms of strangulation, had inflation performed three times without success. Mr. Howse thereupon proceeded to open the abdomen by a vertical incision opposite the umbilicus. The intussuscepted mass was readily felt and drawn out of the wound. It was only by a kind of kneading movement with pressure upon the distal end, that reduction was effected. The length of the included bowel was eighteen inches. The patient recovered without a bad symptom, the wound healing by first intention. In this case, hemorrhage from the bowels was absent, and in their remarks the two gentlemen showed it was of great importance not to delay the operation till hemorrhage occurred. Mr. Hutchinson related a third and fatal case, where the same operation was performed upon an infant six months old, after the other methods of treatment had failed. The intussusception involved the whole length of the colon and the ileo-cæcal valve. Considerable difficulty was encountered in replacing the intestines within the abdomen. They were accordingly pun-

tured with a hare-lip needle in two or three places. Death occurred six hours afterward, and the post-mortem examination showed evidences of recent extensive peritonitis. He was not inclined to consider the length of the incision as unimportant in the operation. There was no analogy with ovariotomy, where one had to deal with flaccid abdominal walls after removal of a large tumor. In intussusception, on the other hand, all the contents of the abdomen that were extended had to be replaced, and this replacement was difficult, just in proportion to the length of the incision, and the amount of the prolapsed bowel. He had sometimes to reduce the size of the incision before he could replace the intestines. The present was the only case in which he had punctured the intestines, and which he hoped never to do again, attributing the fatal issue to this puncture. The general opinion in the discussion seems to have been, that the operation should only be reserved for those cases where all other means had failed.—*The Lancet*, December 18, 1875.

Embolism of the Pulmonary Arteries following the use of Esmarch's Elastic Bandages to the Lower Extremities.—Dr. J. V. Massari reports at length the following case, which occurred at the clinique of Prof. J. Spaeth: A woman, 33 years of age, and in the sixth month of her eleventh pregnancy, was brought in suffering from hemorrhages, which were soon ascertained to be due to placenta prævia. Labor was artificially induced, the placenta separated, and the fœtus delivered in the afternoon. After the operation the patient fell into a condition of collapse, with fainting fits, and difficulty of breathing. An elastic bandage was therefore applied from the toes to the upper third of the thighs of both extremities, with the effect of relieving the urgent symptoms of exhaustion. Stimulants, beef extract, etc., were given, and there was no further hemorrhage. During the evening she complained so much of the pain of the bandages, that they were taken off, but had to be replaced at once on account of the threatening symptoms of pulmonary and cerebral anæmia. The next morning they were once more removed, and again replaced at once for the same reasons. During that day her condition somewhat improved, but at 11 o'clock at night, as she could not sleep from the pain of the bandages, that on the left leg was carefully loosened. At once her face became pale, in her wrists the pulse was lost, there was dizziness, panting for breath, and great complaint of pain and palpitation about the heart. After various remedies, including compression of the abdominal aorta, and restoration of the bandage, had been used, the pulse became perceptible again; but the bad cardiac and respiratory symptoms constantly increased, and she died after two hours. The autopsy was made thirty hours post-mortem. In the pulmonary arteries of the third class on both sides several clots from 3 to 4 mm. thick were found. The saphenous veins also and their radicles, in both thighs, were found dilated, convoluted, and filled with small, partially adherent clots, strikingly resembling those found in the lungs. The author's conclusion is that this thrombosis of the pulmonary arteries, which caused death, doubtless took place when the bandage was taken off the left leg; that the clots came from the region of the saphenous veins, and their formation there was favored by their varicose condition, and the long retention of the bandages *in situ*, being respectively seven and thirteen hours consecutively. The patient also showed an unusually low degree of recuperative energy. We should therefore be very cautious in the use of the elastic bandages where there are any varicose veins, because of the difficulty of completely emptying them as it is applied, and because blood so retained favors the formation of finer clots. The author refers to a similar accident reported by Prof. Kundrat, where flannel bandages had been used over varicose veins.—*Wiener Med. Woch.*, Nov. 27, 1875.

Angina Ludovici.—Mr. F. Murchison has studied a series of peculiar cases of sore throat that he saw among the residents of the Hebrides, during a two years' residence there. He is inclined to think the disease may be angina ludovici, as the symptoms strongly resemble those that have been connected with it by authors. It attacked children and young persons of various ages, the symptoms being uniformly the same. It affected the weak and anæmic in the proportion of six to one of the robust and healthy. All the cases seemed to be idiopathic and independent of any local lesion. They all occurred in winter, and in close succession, but were not confined to one isolated locality. The disease was ushered in by a chill, a stiffness of the muscles that move the tongue and throat, and a general feeling of malaise. After these incipient symptoms, there was a hard swelling in the vicinity of the submaxillary gland, in the gland itself, and in the entire floor of the month, so that the functions of mastication, deglutition, and respiration were seriously embarrassed. From this centre the disease gradually extended until the parotid and thyroid glands were involved. The tumor became harder and pressed the tongue upwards, making it very difficult to feed the patient. This condition continued for twelve days at the longest, when the seat of the inflammation and the throat bulged out like an immense goitre. Some cases ended in resolution, others in the formation and discharge of pus, but none in gangrene or in death. In each case a marked hardness remained, which proved intractable to any remedy except iodine and time.—*British Medical Journal*, December 25, 1875.

Paracentesis of the Pericardium.—M. Roger, in an interesting communication to the Académie de Médecine, has attempted to show in what cases this operation is indicated, and how much benefit may be expected from it. A large effusion into the pericardium affords the primary indication for the operation, but the diagnosis of this is not always easy. The arching forwards of the præcordial region, the flatness, and the functional disturbances are not always reliable signs. Dilatation of the heart, effusion into the pleura, and a mediastinal tumor have been mistaken for effusion into the pericardium. In considering the propriety of the operation, the nature of the effusion and the causes which produce it, as well as its quantity, must be taken into consideration. In hydropericardium and acute pericarditis the effusion can generally be made to disappear by proper treatment. Operation is most frequently indicated in chronic pericarditis, because in consequence of changes in the structure of the pericardium resorption of the fluid has become altogether impossible. Moreover, the pericardial lesions generally persist and prevent a complete recovery. In many cases the effusion is associated with tubercular growths in the pericardium. In operating, the parts to be avoided are the heart, the internal mammary artery, the pleura and lung, the diaphragm, and the liver. The puncture should be made in the fifth intercostal space, a little nearer the nipple than the sternum, and the instrument must be made to penetrate in a straight line from before backwards. This rule, however, may be varied when circumstances require it. The aspirator should be used, and the

trocar is to be as fine as possible. M. Roger has collated fourteen cases in which the operation has been performed, with one perfect and five imperfect cures. In these five cases life was prolonged, and death was finally caused by some concomitant disease. The accident that was most dreaded—puncture of the heart—has not been followed by fatal results.—*Journal de Médecine*, Dec., 1875.

Spider Bite.—Dr. Semple, of Virginia, reports five cases of the bite of a small black spider, in all of which very grave symptoms were produced. The symptoms were a sensation of pricking and itching at the seat of puncture, nausea, and abdominal pains, a sinking feeling in the epigastrium, præcordial pains of great severity extending to the axilla and down the arm, numbness, and in two cases partial paralysis of the arm, apnœa, a very quick, small, and almost imperceptible pulse, great anxiety, and coldness of the surface. The treatment consisted in large doses of whiskey and ammonia, with the bromides of potassium and ammonium in two of the cases. In one case, death being imminent, ten minims of strong aqua ammonia were injected into a vein of the arm. Reaction began immediately, and in fifteen minutes the pulse was full, regular, and only 77 to the minute, the skin was warm and moist, and the respiration natural. The only unpleasant sequel was a small slough, caused by the escape of a few drops of the ammonia into the cellular tissue. All the cases recovered.—*Virginia Medical Monthly*, Dec., 1875.

Parturition in Traumatic Paraplegia.—Drs. Birkerd and C. Lange communicate the details of an interesting case, which shows that parturition may be accomplished by the unaided efforts of the uterus. The patient was twenty years of age, and at the close of the eighth month of pregnancy, when she was upset and thrown into a ditch, a wagon-box falling on her back. After removal to the hospital an examination was made. The patient was lying motionless on her back, in a sleepy condition, able to move her arms, but not the lower extremities. Sensation was very much diminished in the inferior extremities, and she complained of a pricking, buzzing sensation in them. There was also paralysis of the rectum and bladder, and considerable impediment to the respiration. At the level of the fifth and sixth vertebræ there was great tenderness, so much so that pressure on them caused her to scream, and a pain darted through the breast. No mobility or crepitus could be discovered over the vertebral column.

Labor was induced, four days after the injury, by vaginal injections of warm water. The mouth of the uterus dilated, the membranes ruptured, the head came down, and, by the aid of forceps, the delivery of a living female child was completed. The uterine contractions were quite forcible, but could only be detected by vaginal examination, and the mother did not appear to notice what was taking place, talking about other matters. No assistance was afforded by the muscles surrounding the tympanitic, distended abdomen. The placenta was quite adherent to the uterus, and was removed in half an hour by the hand. Very slight hemorrhage. Patient died five days after the delivery. No post-mortem.—*Hospitals-tidende*, Sept. 22, 1875.

A New Operation for Varicose Veins. M. Rigaud, of Nancy, at a recent meeting of the *Académie des Sciences*, proposed a new and simple operation for varicose veins, viz.: simple isolation of the vessels from their sheath. This isolation will invariably produce a coagulation of the blood, not by setting up a phlebitis, nor by retarding the circulation, but by the alterations in the venous walls consequent on cutting off their source of nutrition. The experiments were made upon dogs, the vessel being in each case completely separated from its sheath for a space of two to three centimetres. The first phenomenon noticed was a considerable dilatation of the denuded portion, due to a paralysis of the middle coat. The external surface then became dull, violet or brownish red in color, and gangrenous in spots. As they no longer received any blood through the vasa vasorum, the external and middle coats necessarily became necrotic, and involved in a secondary process of necrosis the endothelium, which derives its nutrition by imbibition from the middle coat. Up to this time the circulation of the blood through the vein had continued, but as soon as the endothelium by its necrosis became a foreign body, coagulation of the blood began and gradually extended upwards and downwards, according to the known physiological laws.—*Gaz. Hebdom.* No. 45, 1875.

A New Kind of Grass-Green Sputum.—Dr. O. Rosenbach, assistant at the Medical Clinique of Jena details the following case, and calls attention to the difference between this and the somewhat similar phenomenon reported by Traube. The patient suffered from bronchial asthma, with attacks of severe dyspnœa and consecutive emphysema of the lungs. During the attacks the sputa were scanty, glassy, very tenacious, of a whitish color, covered with a thick stratum of foam, and themselves filled with air-bubbles. They also contained lumps and plugs of a gray color, in which, as also in the fluid portion, were found numerous pointed octahedral crystals, as described by Leyden. As the attack subsided, the sputa became more abundant, more muco-purulent and fluid, and contained fewer crystals. After allowing such a specimen of the sputa from late in an attack to stand for twenty-four hours, while still free from offensive smell, he found it had become completely green, the coloration being limited to the fluid portion. The fluid was neutral to test paper, but an alkali rendered the green more intense. Under the microscope were found vibriones in abundance, and also light-green spores and larger round masses of small, highly refracting granules, which showed a great resemblance to the clusters of spores. The mucous, pus and epithelial cells were also filled with these small green granules, and they were capable of resisting the action of agents which destroyed the cells. Dr. R. therefore connects the color of the sputa with the clusters of spores, and he found he could propagate them and produce the same coloration in the sputa of a phthisical patient and in milk.—*Berliner Klin. Woch.*, November 29, 1875.

Salicylic Acid for Typhoid Fever.—Dr. T. J. Pitner, in a letter to the November number of *The St. Louis Med. and Surg. Journal*, from Leipsic, speaks of the use of salicylic acid for the treatment of typhoid fever, in the wards of the hospital, which are under the direction of Prof. Wunderlich. The results are described as remarkable. The most striking and uniform effect was a fall in the temperature within twenty-four hours after the administration of the remedy. The dose was one gramme (fifteen grains) in solution in water, repeated three or four times during the day. The average decrease in the temperature is stated to be about three degrees Fahr., though it sometimes fell as much as from 104 to 99 Fahr. The fall of temperature was accompanied by a like ameliora-

tion of all the other symptoms. Prof. Wunderlich, in speaking of the value of the remedy, declined to express himself definitely as to its merits, "but mentioned the fact of the fall of temperature as full of promise for its usefulness." It had only been on trial for two months.

A Case of Hæmatidrosis.—Dr. M. Tittel reports the following case: The patient was a strongly-built man of twenty years, belonging to a well-to-do and healthy family. He stated that when twelve years old he had an eruption of red spots upon the face, and they were circumscribed, non-elevated, painless, and did not itch. At the time of their appearance his face was extremely pale, and he suffered from great fatigue and headache. They disappeared after two months without medical treatment. He also stated that a year later, after being severely chastised by his father, blood at first actually spirted, and afterwards ran steadily and slowly, from the dorsal surface of his left hand, although there was not the slightest wound on the hand. This lasted for some days, and then stopped. It was succeeded by great mental depression and noticeable sluggishness. He stated that he subsequently had other hemorrhages, and that they assumed the character of blood-sweating, so that his shirt, his neck-handkerchief, and his stockings, would get of a rusty color. Dr. Tittel had at length an opportunity of witnessing one of these attacks personally. He found that it was accompanied by a decided diminution in the frequency of the pulse, viz., from 60 to 40 beats per minute. The hands and feet were somewhat swollen. The surfaces most affected were the throat, the volar surface of the hand, the anterior surface of the leg and the feet. At the same time the patient complained of fatigue, headache, dizziness, weakness, and disinclination for work, and these symptoms always preceded an attack. The stools and urine were free from blood. On microscopic examination, the discoloration of the clothing was found to be due to blood, and, on examining the patient, the doctor saw blood actually oozing from the orifices of the sweat glands on the forehead, and even more distinctly in the palm of the left hand—an observation which was confirmed by Prof. Wagner and several other physicians named. On reviewing the literature of the subject, the author finds many cases of greater or less authenticity recorded, and a prevalent impression among the older writers that such hemorrhages are connected with violent mental disturbances, or with physical excesses, or, again, that they are in the nature of vicarious menstruation. In the present case the microscope showed that the hemorrhage was through the canals of the sweat-glands. He can throw no light upon the etiology of the affection, and can only ascribe it to a lesion in the innervation of the capillaries of the skin. The patient subsequently joined the artillery, and had no more hemorrhages.—*Archiv der Heilkunde*, Nov. 22, 1875.

Hooping-Cough treated by the Iodide of Silver.—Dr. Robert Bell, of Glasgow, has treated over one hundred cases with this substance, and with uniform success. He uses no other remedy, except occasionally ten or fifteen grains of bromide of potassium at bedtime. In almost every case treated by the iodide of silver, the cough lost its hoop in four weeks, and was well in six weeks. Similar results were observed where two or more cases occurred in the same family. One eighth-of-a-grain doses three times a day were given, in a case illustrative of the treatment. He says he does not attempt to explain the precise action of the iodide, but that hooping-cough being a disease of the gastric periphery of the pneumogastric nerve, the silver salt acts as a sedative to this morbidly sensitive nerve, preventing reflex irritation being conveyed to its pulmonary ramifications.—*The Obstetrical Journal*, December, 1875.

Great Development of Amœbæ in the Large Intestine, associated with Dysentery.—The following case is reported by F. Lösch, from the clinique of Prof. Eichwald, of St. Petersburg: A farm-laborer, twenty-two years of age, contracted in 1871 an obstinate diarrhœa which lasted six months or so, and left him so weak that he was not equal to military duty. He recovered somewhat, however, and became a lumberman. The wet and cold to which he was exposed in this employment brought back his trouble in the form of severe dysentery, so that at the beginning of November, 1873, he was received into the hospital. His stools at this time were found to be scanty, fluid, foul-smelling, and of a reddish-brown color, and to contain yellowish-white and grayish-red masses of mucus and pus. On microscopic examination there were found large cell-like bodies, in part free and in part enclosed in mucus, which, from their peculiar motion, were recognized as animal parasites, in fact as amœbæ. All the ordinary modes of treatment for chronic dysentery were used without more than a transient benefit, and then carbolic acid was given internally and by enema. This did no better. At the same time it was observed that there was a certain relation between the quantity of the parasites and the intensity of the symptoms of the disease, both increasing together. This circumstance with others, and with the result of experiments made upon dogs, induced the physician to give quinine, thinking it unlikely that he could cure the disease until he had destroyed the parasites, which seemed to keep it up. It was, therefore, given by mouth and rectum. The results were very gratifying, the patient improving in every way, and by the end of ten days not an amœba could be found in the stools. Still they had not all been destroyed, for after the quinine had been discontinued for a few days, they returned in full numbers, and all the bad symptoms returned with them. In fact, the patient's condition became so bad that transfusion was resorted to about the middle of February to save his life. Soon after this he began to have a cough. On March 9 he had a chill, followed by fever and the development of pleurisy, with effusion; and, strange to say, at this time the character of the stools changed to that of typhoid-fever evacuations, and the amœbæ entirely disappeared from them. The author can offer no satisfactory explanation of this fact. However, the effect on the bowels was most favorable, the passages soon becoming almost normal in character and frequency. On April 12, however, the patient died from cheesy pneumonia. At the autopsy the large intestine exhibited inflammatory thickening of its submucous layer; there were ulcers and cicatrices, and abundant pigmentation, also numerous mucous cysts, all these appearances being most marked in the descending colon, and the vicinity of the sigmoid flexure. The author gives a very detailed account of the amœbæ found in the stools, and discusses them with this conclusion, viz., that they did not correspond with any forms hitherto described, and therefore he names the variety *amœba coli*. He is satisfied that the amœbæ had an essential influence upon the symptoms of the disease, keeping up the inflammation and preventing the ulcers from healing. His view of the case, as a whole, therefore, is that the patient first contracted the dysentery, and that subsequently the amœbæ found entrance, and kept up the inflammation.—*Virchow's Archiv*, Nov. 10, 1875.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, February 26, 1876.

THE ETHICS OF CONSULTATION.

THE relations which we should sustain to each other, especially in the matter of consultations, are so important that we cannot have our attention directed to them too often. If all the medical men in the land were actuated by the proper spirit, there would be no difficulty in settling doubtful points of etiquette, and there would be no such abuses of privilege, and no such violations of confidence, as we are so constantly compelled to notice. As we have often said, the very existence of a code of ethics in our profession is a reflection upon the honesty of our intentions; but unfortunately there is a necessity for it, in consequence of advantages which are often taken by some of the meaner spirits. There is so much temptation with the latter for unfair dealing, there is no wonder that there are many abuses to correct and many reforms to advocate. In some sections of the country there is no delicacy whatever in directly interfering with each other's rights, and physicians do not hesitate not only to denounce each other's practices in the sick room, but to engage in professional fights in their village papers. But with these we have no special concern at present. We only desire to call attention to some of the less overt violations of professional obligations in regard to consultations, because they are more common, and, from the fact of not being so readily appreciated and detected, are really more dangerous.

Take the following example: A young man, actuated by the strictest regard for the good of his patient, asks for a consultation, and chooses for his consultant a gentleman of experience and standing. In securing the object of his choice he takes pains to impress upon the patient and his friends the importance of having an opinion such as this distinguished member of the profession can give. The consultation is held, and the younger member behaves himself in a becomingly respectful manner towards one who he acknowledges is his superior, and is satisfied, as he certainly has a right to be, that no advantage will be taken of the circumstance by the new-comer. The patient's friends are not so easily satisfied, and, knowing something of the conventional trammels of etiquette, manage to secure a private interview, which, with shame be it said, is granted.

"Well, doctor, what do you really think of John's case?"

And this is the reply:

"I think that the patient will get along. The doctor seems to understand the case very well for a young man. It is true there was some little difference of opinion in regard to the plan of treatment, but the doctor very kindly listened to my suggestions, and will doubtless heed them."

Then follows some smiling allusions to medical etiquette, how wrong it is to destroy confidence in the attending physician, how necessary it is that the present attendant should be continued, if for no other than ethical reasons, and the consulting physician bows himself out, leaving his unsuspecting victim with a damaged professional character. We do not wish to be understood as drawing upon our imagination and making this a supposable case. On the contrary, the example is founded on a fact, and the dialogue is reported almost exactly as it occurred, and by one of the friends of the patient who was present at the time. And this is not an isolated instance of its kind. Numerous examples of the same sort of double-dealing have come to our knowledge, and they are constantly occurring all over the country.

It is unnecessary to refer to the many similar opportunities for the consultant to make capital in the sick room, by acts which are not punishable by the code, a timely shrug of the shoulder, a significant elevation of the brow, a peculiarly anxious attention to the patient's history of his case, and many other matters. Neither is it necessary to say how often they take advantage of the situation. These are acts which are capable of a charitable construction, and we naturally give them the benefit of a doubt. The patient, too, is magnanimous in supposing that the consulting physician is doing his best to suppress his natural feelings. But when words are spoken, and distinct impressions conveyed, the case is different, and we have something positive upon which to base assertions.

It may seem a bold thing to say, but we nevertheless believe it to be true, that the desire for professional advancement and pecuniary gain is so strong with some of the profession, that almost every consideration is lost sight of in its gratification. Medical etiquette, it is true, offers a slight barrier to the base purposes of unprincipled men, but even this is easily broken down. There is, too, a certain class of professional men, who are bold, ambitious and grasping, who are always willing to help others a little, to be helped themselves a good deal, but so soon as this

relation of *quid pro quo* is disturbed, even medical etiquette cannot prevent the quiet crowding down of one who aspires to something more than second-rate. When patronage ends, war generally begins.

It would seem, as far as these practices are concerned, at least, that the ethics of the profession were made to enable the larger fish to feed upon the smaller, so that the latter could never arrive at maturity.

A NEW TIME-SAVING METHOD OF SECURING A DIPLOMA.

Probably there has been no more original plan of saving time in the acquirement of a medical education than that inaugurated at Louisville, Kentucky. In these days of the wholesale manufacture of doctors, it is interesting to know of some of the secrets of the trade, some of the means adopted by respectable colleges to increase their constituency and swell their incomes. We believe this enterprising Western town is entitled to the credit of an innovation, which consists, as we understand it, in crowding two courses into one year, at the end of which time, both courses being full ones, the student may graduate. It is managed in this manner: The Louisville Medical College gives a winter course in the regular way, and the Kentucky School of Medicine gives a spring course. This may appear perfectly proper, until we know that but one faculty controls both institutions; that is to say, the professors of the winter course in the Louisville Medical College are (with one exception) the professors in the spring course in the Kentucky School of Medicine.

Declaring themselves two distinct institutions, each capable of giving a full course and a medical degree, there is nothing whatever, so far as we can see, to prevent the winter-course students in one school from becoming spring-course students in the other, and, at the end of the latter course, of graduating in medicine. The excuse for thus infringing upon the rights of medical education is presented with all the candor of gentlemen who are evidently determined to cater to the wants of those students who wish to be put over the road in the shortest possible time. Among other reasons, the announcement presents this one: "Because there is no known reason why students should be compelled to defer attending a lecture course until October of each year." Certainly not, except he has commenced one the year before at that time. And again, the same announcement says: "Because large numbers of the best young men are always anxious to complete their collegiate studies without the intermission of the summer months." We have no doubt that there are a large number of the young men whose wishes in regard to the through-ticket system would be gratified, but we are hardly prepared to admit that they are the "best" men.

What, however, is more amusing than anything else connected with this copartnership scheme is the following: "Lastly, because it is believed that while any chartered medical institution will justly forfeit the respect, confidence and support of the profession if it gives two graduating courses in one year, the Kentucky School of Medicine now reorganized will act most judiciously and with manifest propriety [*sic*] by selecting the spring as the period of its single annual course." Here the passengers for the through trip stop for refreshments, have their tickets punched, and take the forward cars. This is the only change necessary over the new branch of the road.

Another striking evidence of copartnership between the two schools is the following official statement:— "The graduate of this college [Kentucky School of Medicine] will every year receive in addition to his own diploma the *Ad Eundem* degree of the Louisville Medical College, whose annual session, commencing every September, closes in the last week of the following February. This *ad eundem* degree is furnished without cost."

Dr. Cowling, the editor of the *Louisville News*, in discussing this question of identity, makes the following comment:

"We confess that we are too dull to see where the claim for separate existence comes in. We feel rather sure that we cannot praise the 'Louisville' without making the 'Kentucky' blush, nor blame either without expecting to encounter the swords of both. The phenomenon has in common brain, heart, and lungs. We will be perfectly honest in calling it the Louisville-Kentucky School of Medicine. *It holds two graduating courses in one year; it graduates students of medicine in nine months, and presents each with two diplomas.*"

This, then, appears to be the gist of the whole matter, and our Western brethren deserve the credit of initiating the easiest and quickest method of obtaining a double-headed diploma of which we have yet heard.

Reports of Societies.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, January 22, 1876.

Dr. Charles K. Briddon, President, in the Chair.

CANCER OF TONGUE AND JAW—OPERATION FOR REMOVAL—DEATH—OPIUM-EATING.

Dr. Post presented several specimens, the first of which was one of malignant growth of the floor of the mouth, the lower surface of the tongue, and the parts in front, involving the bone itself, and the integument in front of it. The latter condition was not recognized, however, until the time of the operation. The patient, a male, æt. 50 years, was admitted to the Presbyterian Hospital three months since, presenting an indurated ulcer below the tongue, concerning the diagnosis of which between cancer and syphilis there was at first some difficulty. Anti-syphilitic remedies were employed, but with no marked effect, and the

patient's condition after a time grew gradually worse, being unable to swallow except with great difficulty, and suffering a great deal of pain. The suspicion of the malignancy of the growth being confirmed, and the prospects of the patient being desperate, an operation was determined upon, for the purpose of a temporary relief to his sufferings. It was performed by dividing the lower lip from each angle of the mouth downwards, and making a section of the jaw at the corresponding points. The tongue was drawn forward, a large portion of which was removed. It was then found that the morbid growth had perforated the jaw and involved the integument in front. A considerable but not an excessive quantity of blood was lost in the operation.

On the morning after the operation the patient was able to swallow without much difficulty. His pulse was fair, but he was quite restless, which latter was in a measure accounted for by the absence of a large portion of his tongue and the drawing forward and fixing of the remaining portion to guard against the danger of falling into the larynx. The patient died in less than twenty-four hours after the operation, from nervous prostration, which probably was somewhat connected with the habit of opium-eating which he had acquired.

EPITHELIOMA OF TONGUE—OPERATION.

The second specimen was one of epithelioma of the base of the tongue and mucous membrane of the sublingual gland, removed by operation from a female, aged 73 years. The disease was of five months' duration, attended with but little pain, and was not ulcerative. A simple, straight incision was made in the median line of the chin, the jaw divided and drawn asunder, when a platinum wire was attached to Dawson's battery and passed around the growth under the tongue. Contrary to expectation there was a good deal of bleeding, necessitating the ligaturing of the lingual and sublingual arteries. The other portions of the tumor were removed without difficulty, the severed ends of bone wired together, and the integument united by sutures. The prospect of union by first intention was good.

ENLARGED PROSTATE—FALSE PASSAGES—CALCIFIED TUNICA VAGINALIS.

A third specimen was taken from a man, aged 73 years, who came into the hospital suffering from symptoms of enlarged prostate and partial retention of urine. After admission, and after the patient supposed that he had entirely emptied the bladder, Dr. Post introduced a catheter and drew off twenty-four ounces of urine. There was a difficulty in introducing the catheter, other than that occasioned by enlarged prostate, the instrument being deflected to the right by a false passage. The patient also had a sarcocele of one side and a calcification of the tunica vaginalis. He died a few days after entering, from disease of other organs than those to which attention had been primarily directed.

The following were found on autopsical examination: Extensive tuberculosis of lungs, with secondary pneumonia, dilatation of right ventricle of heart, with a large clot in right auricle, probably ante-mortem. The kidneys were the seats of waxy degeneration. The tunica vaginalis was calcified, and there was a false passage running parallel with the urethra and communicating with it at intervals by four distinct openings. The prostate was enlarged, had a large pouch behind it, but in place of the enlarged third lobe there was found an extra growth alongside, which was somewhat pedunculated, and doubtless acted as a valve during life. The bladder was sacculated, as might be inferred from the damming of the urine after the patient supposed the viscus empty.

MALIGNANT DISEASE OF ANTERIOR WALL OF BLADDER, WITH SYMPTOMS OF STONE.

A fourth specimen was one of malignant disease of the anterior portion of the bladder, which in consequence of a calcareous deposit on the surface of the growth, with other rational symptoms, gave some of the physical evidences of calculus. The patient was repeatedly examined with the sound, but with somewhat varying results. In the first examinations the instrument having grated upon some solid and rough surface, the suspicion of calculus was apparently well enough established to warrant the introduction of the lithotrite. Two operations were performed with this instrument at different times; at the first a minute calculus was extracted, and at the second another was instantly seized, crushed, and lost. Although at different times the instrument struck, and always in one situation, what appeared to be a calculus, the diagnosis was not certain. With a view of clearing up doubts upon the subject, Dr. Post introduced his hand into the rectum, with the view of examining the bladder, but the fingers were so cramped in a cone-like position that nothing satisfactory could be gained. On subsequent sounding, Dr. P. felt so well assured that an encysted stone existed, that he performed cystotomy with a view of making a free outlet for morbid discharges, and of removing the calculus if one should be found. The usual bilateral incision was made, but the perineum being very deep the position of the supposed stone could not be reached with the finger. The forceps was then introduced, and a number of efforts made to disengage the foreign body, but with no avail, and as far as lithotomy was concerned, the operation was unsuccessful. The patient, however, expressed himself much relieved by the free discharge of the products of inflammation through the wound. In the course of ten days after, several hemorrhages occurred; these were followed by chills, slight increase of temperature and pulse, and the patient finally died, and what was supposed to be encysted calcareous disease was a malignant growth encrusted with calcareous deposit. The patient was 53 years of age.

FIBRO-RECURRENT TUMOR OF GLUTEAL REGION.

A fifth specimen was a fibro-recurrent tumor removed from the gluteal region of a woman aged 35 years. The growth was secondary, a previous operation having been made a year before.

Dr. Post lastly presented two wedge-shaped portions of bone removed by operation from the knee of a man, 50 years of age, for the purpose of correcting a deformity and uselessness of a limb, the seat of bony anchylosis. An H incision was made over the knee, dividing the ligamentum patellæ. It was then found that bony union existed with one of the condyles and the corresponding portion of the tibia, while in the opposite condyle there were some traces of synovial membrane. The patella itself was free. A wedge-shaped portion was removed, but not being sufficient to bring the leg nearly in the straight position, another wedge was sawed out. The divided portions of bone were then brought together with wire sutures, the wound closed, side splints applied, and the limb placed in a fracture-box. There were no signs of

constitutional disturbance after the operation, and the prognosis was good.

Dr. Mason referred to a calcified tunica vaginalis in the museum of Charity Hospital.

Dr. Weir remarked that Dr. Post had given him an opportunity in the case of malignant disease of the bladder to hold the forceps after it had been introduced, and he felt distinctly the grating sensation. He had been deceived once before in a somewhat similar case, after the division of a stricture.

Dr. Burchard referred to a case somewhat similar to this one of Dr. Post, in which Prof. Diddell, of Strassburg, performed the median operation for lithotomy, and removed the growth, likewise situated on the anterior surface of the bladder. The recovery of the patient was apparently complete.

CANCER OF THYROID GLAND—DEATH FROM ASPHYXIA.

Dr. Weir presented a specimen of cancer of the thyroid gland, removed post-mortem from a woman, 68 years of age, a patient of Roosevelt Hospital. The disease was of less than ten months' duration, had grown with great rapidity, and during the last two months of life caused considerable dyspnœa. At the time of her admission into the hospital, in June last, the tumor measured five and a half inches across, and one and a half on its vertical diameter. It was uniformly hard, encircling the trachea and neck as a large collar, terminating rather abruptly on the right side, and fading into the surrounding tissues on the left side.

During her stay in the hospital she suffered from repeated attacks of dyspnœa, but as these were markedly mitigated by opiates there did not seem to be any urgent need for operative interference until she was sufficiently improved in her general condition. Finally, the day was fixed for the operation, but two hours before the time of the latter she died in a fit of dyspnœa.

At the autopsy the growth, which was truly cancerous in character, was found to involve the trachea, passing between it and the œsophagus, not involving the walls of the latter, but encroaching upon the calibre sufficient to produce the dysphagia of which she complained during life. Dr. Weir then referred in detail to the operation he intended to have performed had the patient lived, and concluded by remarking upon the extreme rarity of the disease in question.

ORIGIN AND PROGRESS OF MAMMARY CANCER.

Dr. Delafield presented a section of the mammary gland, showing the origin and progress of true cancer of that organ. There was no extra development of connective tissue or connective-tissue cells, and the purely glandular element of the growth was very satisfactorily exhibited. The gland ducts were all enlarged and completely filled with epithelial cells. The same was the case with the acini. It was, then, an example of true cancer, involving the greater part of the mammary gland, beginning as an increase in the epithelial cells of the ducts of the gland and acini of the gland, and going on as an infiltration of the lymphatics with these same cells. The disease originated in the ducts of the nipple, and involved the lymphatics secondarily. The organ was removed by Dr. Weir.

Dr. Weir stated that the patient was 45 years of age, unmarried, was considerably emaciated, but in fair health, and no secondary glandular enlargements.

BRIGHT'S DISEASE AND SYPHILITIC PACHYMENINGITIS.

Dr. A. H. Smith presented a brain, removed from a male patient of St. Luke's Hospital, admitted Sept. 25th, and aged 35 years. For two years before his admission he had been passing more than the normal quantity of urine, and his urine having been examined about that time he was told that he had diabetes. The quantity of urine fluctuated very much during the whole of his sickness; at times it was equal in quantity, as he said, to two chamber-potfuls in twenty-four hours, while at other times it would be normal.

Eighteen months previous to admission he began to complain of pain in his head. His general health deteriorating he went to the country to recruit, but without success, and when he was seized with a slight convulsive attack, becoming alarmed, he repaired to the city again and there sought admission into the hospital. During the first day he passed 86 ounces of urine; the second day, 56; and the third, 30; and the fifth day it was reduced to 17 ounces. No sugar nor albumen was discovered.

Ten days after admission he was seized with a uræmic convulsion, when the urine became albuminous, and smooth, hyaline casts made their appearance. From this time he began to be stupid, and this condition increased until he died.

The kidneys were found, on post-mortem examination, to be in the condition of chronic Bright's disease. All the other organs were healthy, except the brain. On the anterior aspect of the left hemisphere a large patch of the dura mater was very much thickened and adherent to the brain, the latter being softened at the point of contact. Just above the left occipital protuberance the scalp was adherent to the skull, marking the site of the kick of a horse when a boy. The history of syphilis was not satisfactory, although there were numerous suspicious spots over his body, and there was an abatement of the symptoms under specific treatment.

NEW YORK MEDICAL JOURNAL ASSOCIATION.

Stated Meeting, February 11, 1876.

Dr. F. P. Foster, Vice-President, in the Chair.

FACTS AND SUGGESTIONS REGARDING THE TREATMENT OF THE INSANE AT OUR CITY INSTITUTIONS.

The object of the paper read by Dr. R. L. Parsons upon the above subject, was to show what improvement has been provided for the better care of the insane during the past year, particularly at the New York City Lunatic Asylum upon Blackwell's Island, and to give suggestions relative to what is yet required in order that this unfortunate class of persons may be properly cared for and maintained.

Among the reasons for bringing this subject before the medical profession was the pungent one that medical men know too little upon this subject.

The first improvement mentioned was the introduction of the pavilion system, and it was believed that by this means certain classes of patients can be more easily cared for and supervised. Two pavilions have been constructed, three more are in process of construction, and each has an estimated capacity for the accommodation of sixty persons. In a pavilion having a large central hall with wings upon either side, much less air-space is required for each person than when the building is cut up into rooms. These pavilions at present are heated by means of stoves, but perhaps hot water might be substituted with advantage. The average cost of a pavilion to accommo-

date sixty persons is $6,000, and this was regarded as economical, even if it became necessary to remove them every few years and construct new ones. Another advantage claimed for them was that they are more cheerful and home-like, and there is less appearance of restraint than in a building containing several stories and a multitude of rooms enclosed by heavy stone-walls. Another advantage is the facility with which patients can be got out into the open air. These were the chief advantages urged in favor of the pavilion system, and they are essentials in the proper treatment of the insane.

There are some disadvantages, such as the fact that they require a greater space to accommodate the same number of patients; the labor attending the heating is greater; and the labor in distributing the food is greater. The first cost of heating apparatus is less. The greatest difficulty attends the proper distribution of the food. The difficulty of supervision by the medical staff is also somewhat increased. Another disadvantage consists in the difficulty of securing efficient supervision during the night, for night-watchmen are required for each pavilion, and night-watchers to prevent interference with the fires, etc. If the room is heated by steam no night-watchers would be required.

Heating by steam also has its disadvantages. For it necessitates covering the pipes with some fabric, and with this comes the difficulty of keeping such covering free from dust and organic matter. Probably the organic matter which comes in contact with the pipes and becomes roasted will not act prejudicially to the best interests of the occupants, but the dust may be a serious disadvantage. The coverings of the pipes, therefore, should be fitted in such manner that they can be easily removed and replaced.

Radiated heat exercises a stimulating influence upon the tissues, while conducted heat, rarefied air, is enervating, and tends to produce relaxation of tissues.

The temperature of a room in which there is an open fire is equally comfortable at 60° F. with a room heated to 70° F. by means of conducted heat

The use of steam radiators for heating purposes was recommended.

There are three considerations which should enter into the making-up of the diet-list.

1. Sufficient quantity of nutritious food;
2. As great variety as practicable;
3. The food should be cooked well, and with as much variation as circumstances will permit. As a corollary, the manner of serving the food should be as nearly like that employed in ordinary life as possible. Ripe fruits are exceedingly beneficial. Extra diet upon holidays, accompanied by extra entertainments, are fully appreciated, and contribute very materially to the general improvement of these patients.

A hall has been constructed in which gymnastic exercises can be taken, and theatrical performances and concerts given for the amusement of the patients. Amusements are of the greatest possible benefit in the treatment of the insane.

Improvements have been made so that the patients now have red flannel under-clothing when sick in bed, and cotton flannel when in ordinary health.

Excited patients are under constant supervision, and provisions are now made for this class, which are more complete than they have been for many years.

There is a feeling abroad, and it has also taken an official form, that the dormitories for the insane of our city are nothing more than almshouses, and that their occupants should simply be regarded as paupers. Hence there is a feeling that only such provisions should be made for the insane as are merely necessary to sustain life. For, it is urged, if more is done for paupers, our institutions will be filled to overflowing, and the crowd will increase with increasing accommodation. While this may be true with reference to the inmates of almshouses, the principle is not applicable to lunatics. Only a very small proportion of the insane were paupers before becoming insane, but were nearly all useful and law-abiding citizens. Making generous provisions for the care and cure of the insane is really the best method that can be adopted to reduce the number of insane patients.

The present expense for maintaining each patient one day, including food, medicines, clothing, salaries of attendants and medical staff, is a little over twenty cents.

Parsimony, and not economy, is the word to be used when speaking of such stinted expenditures. What is really needed is one attendant to every twenty patients. The force of medical attendants is not sufficiently effective, and should be very much increased.

The present capacity of the wards of that institution is not sufficiently ample to prevent the necessity of making beds upon the floor for the accommodation of 320 patients every night.

Although pavilions are adequate for the care of quiet patients, the most approved structures are necessary for the proper care of the excitable patients. Such buildings are necessary for the proper management of this class of patients as will render it possible to completely isolate them from each other.

It remains a noteworthy fact, that although improvements have been secured, such as better diet, better clothing, better domiciliary accommodations, a hall in which relaxation and amusements can be furnished, yet the New York city institutions for the insane have most inadequate provisions for the proper management of their inmates.

Dr. Ludlum drew attention to the fact, that a gentleman in London had proposed to furnish food in a hot state at any point twenty miles distant upon a direct line of railway. The food is placed in tin boxes, which are placed within wicker baskets that are lined with felt, and covered tightly with a cover lined with the same material. Dr. Ludlum inquired of Dr. Parsons whether this plan had ever been tried upon the Island?

Dr. Parsons replied that the precise plan had not, but that he had a similar arrangement for transporting food, so that it might be delivered to the patients while warm.

Dr. A. C. Post referred to the fact that in Norway the peasants were in the habit of carrying their food in felt-lined vessels, where it would retain its heat for several hours. The doctor further remarked that an objection to steam radiators for heating purposes was the fact that radiators do not secure any ventilation. They simply heat the air in the room without producing any circulation, except the imperfect circulation set up in the air which comes in contact with the radiators, and circulates over it. A proper thermal ventilation is secured by heating a room with air which has been heated by passing over hot pipes. Ventilation by opening windows and doors establishes currents which are oftentimes injurious to health. Warm air is just as pure as cold air, although it contains less oxygen, and it is much more comfortable. Open fires would be preferable for heating and ventilating purposes, but in our cold climate they could not be adopted, especially in our large institutions, without an enormous expense for fuel.

Dr. McDonald corroborated the views of Dr. Parsons, as expressed in the paper, and regarded it as very poor economy to bring the supplies and attentions for the insane down upon a level with those afforded for paupers. He also referred to the introduction of the new diet-list into the asylum for insane on Ward's Island, and stated that the average death-rate for nine months previous to its adoption was 14 a month. The first month after the introduction the death-rate was reduced to 10, the second to 8, and the third to 4, and that at a season of the year, October, November, and December, when the highest death-rate was expected. The expense for food was increased, but the bills for medicines and liquors were notably diminished in size.

Dr. Beard remarked that the corps of attendants at our institutions for the treatment of the insane was not sufficient to permit any scientific experiments of value to be made. In a majority of asylums the treatment is thoroughly routine, and scarcely any advance has been made for these many years. Now that we know insanity to be a disease of the brain, it would seem that much advance might be made by well-directed experiments with reference to the effects produced by various remedies. In this direction there is an immense field for operation in our asylums, providing they were furnished with an adequate number of assistants. The single item of improvement in diet has been followed by marked benefit, and doubtless much benefit could be derived from the use of various drugs, and watching carefully the results obtained. Not only could advances be made in the treatment of the insane, but in the treatment of nervous diseases in general.

Dr. E. C. Seguin regarded an increase of the medical staff as one of the most important of the subject which call for reform in our public institutions. This evil is of a twofold nature: 1, overwork; 2, insufficiency of remuneration. In our insane asylums there are from four to six hundred inmates under the supervision of one man. The result is that the superintendent can give but little information concerning the patients, or has but little at his command except what is obtained by reference to the books. The assistants do not number more than two or three, and with such a number of patients it is impossible to give thorough care and investigation to each patient. The fact that some are chronic cases, requiring but little or no attention, does not help us out of the dilemma; for many of these cases which are regarded as chronic are in a condition in which proper attention would be of immense benefit. Many instances of cure have occurred after the patient has been insane for eighteen months or two years. The number of assistants to properly carry out artificial feeding in such cases as require it; to use the hypodermic syringe, as in the later treatment of melancholia by means of hypodermic injection of morphia; to weigh the patient, use the thermometer, sphygmograph, etc., etc., is entirely inadequate.

In many of these institutions there are no provisions for a library, and in scarcely any are there adequate provisions for pursuing pathological investigation. These are some of the obstacles to be overcome, if the greatest benefits are to be given to the inmates of our insane asylums.

Non-Impregnated Uterus.—At a recent meeting of the London Obstetrical Society, Dr. John Williams stated that the multiparous uterus could be diagnosticated from the nulliparous by the permanent alteration of the arteries of the former.

Reports of Hospitals.

BELLEVUE HOSPITAL.

Notes of Practice and Peculiarities of Treatment.

An unusual complication of typhoid fever—capillary bronchitis.

This case illustrated one or two points of interest, which will be mentioned in the history, but the special item was an unusual complication.

A female patient, æt. 15, was admitted to the hospital, Aug. 28, for some local affection, which had no bearing upon her subsequent illness. On Sept. 3 she walked about the ward some, and also up to Sept. 15, but at that time suffered somewhat from diarrhœa; had been listless for a day or two and appeared to be very weak. She had also had a trifling amount of bronchitis. In the afternoon of the fifteenth or eighteenth day after admission, it was noticed that she was extremely feeble, manifested some tremor, complained of some pain in the chest, and also of feeling cold. It was suspected that pneumonia might be developed from the increased severity of the symptoms, but physical examination determined only an extension of the inflammation to the smaller bronchial tubes. On Sept. 16 her condition was worse, respiration rapid, face flushed, and râles so abundant that a vibratory motion was communicated to the walls of the chest, which could be easily recognized by the hand, and there was also an abundance of *fine* râles. At that time the temperature was found to be 106° F. This was regarded as a point of interest, and gave rise to some difference of opinion regarding diagnosis; for this high temperature was such a marked variation from the general rule in the formative stage of typhoid fever, that there was an inclination upon the part of some of the visiting staff to exclude that disease. But the sequel proved that the laws of temperature in disease are laws which have exceptions, and that the observer must take cognizance of the exceptions as well as the laws. In this case, however, the early complication, capillary bronchitis, probably accounted for the high temperature.

Sept. 17.—Her temperature was 102¼° F. in the morning, and in the evening 105° F., with a morning pulse of 110 and R. 32; and in the evening P. 118, R. 36. Here was another point worthy of note, namely, increased frequency of respiration *out of proportion* to the increased frequency of pulse. From that fact it was observed we had a right to infer that there was some pulmonary affection present in the case.

Sept. 18.—Morning temperature 105° F., P. 160, R. 35; evening temperature 103¼° F., P. 112, R. 29.

Sept. 19.—Her temperature was 105° F., and R. 40.

Sept. 20.—Temperature 102½° F. morning, and 104½° F. evening; R. 46 morning, and 48 evening.

Sept. 21.—Temperature 103¾° F. morning, 104° F. evening; R. 40 morning, 42 evening.

Now it was noticed that an eruption was present upon the abdomen, having the characteristics of the typhoid, and it was seven days after the patient had taken to her bed, which made it about the classical time for the appearance of the typhoid eruption, reckoning the commencement of the disease at the time the patient takes to the bed, as is the custom with some observers. The temperature rose to 106° F. and

106¼° F., and continued high until the 27th, the day previous to death, when it fell to 105° F., and upon the day of death to 102¾° F. morning, and evening 103¾° F. The complication of capillary bronchitis in this case was regarded as *very rare*, whereas an ordinary bronchitis is almost constant.

CHANGES IN THE PUBLIC SERVICE.

Official List of Changes of Stations and Duties of Officers of the Medical Department United States Army, from Feb. 13th to Feb. 19th, 1876.

ARMY.

HARTSUFF, A., Assistant Surgeon.—Granted leave of absence for one month, with permission to apply for an extension of five months. S. O. 17, Department of the Platte, Feb. 11, 1876.

WEISEL, D., Assistant Surgeon.—Assigned to duty as Post-Surgeon at McPherson Barracks, Atlanta, Ga. S. O. 24, Department of the South, Feb. 16, 1876.

DELANY, Alfred, Assistant Surgeon.—Died at McPherson Barracks, Atlanta, Ga., on Feb. 14, 1876.

Medical Items and News.

BELLEVUE HOSPITAL MEDICAL COLLEGE.—The Fifteenth Annual Commencement was held in the Academy of Music, on the afternoon of February 21st, at which time the degree of Doctor in Medicine was conferred by the President of the Faculty, Prof. Isaac E. Taylor, upon 159 graduates. The audience was brilliant. The music was furnished by a grand orchestra under the direction of Mr. Carl Bergmann. The Hippocratic oath was administered to the class by the Rev. Dr. Beach, Chaplain of the College.

The following prizes were awarded: to John A. Wyeth, M.D., of New York, the Wood prize of the Alumni Association, $100, for the best essay; to P. J. Higgins, the first Mott prize, $50, for the best clinical report; to Seth W. Williams, the prize for the best examination in Physiology, established by Leonard J. Gordon. Honorable mention was made of the examinations for this prize passed by J. A. Coogan, W. A. George, J. H. Jackson, G. H. Magness, H. Muhlfeld, F. A. Rice, F. R. Sherman, E. H. Tyler.

The address to the graduating class was delivered by Prof. A. B. Crosby, who laid before them in fitting words what may be accomplished by enthusiasm. Enthusiasm involves the idea of energy, work, and pluck. To work in a profession so laborious, self-sacrificing, impecunious, requires enthusiasm. The broad field of incessant scientific activity demands enthusiasm. A few well-selected text-books, if well mastered by a working enthusiasm, are far better than shelves covered with half-read volumes. Enthusiasm properly directed can never be rode to death, and if the doctor will work with enthusiasm he will find that the righteous man is not forsaken.

The valedictory address was delivered by Charles W. Cropper, of Illinois, and possessed the merit of brevity without being altogether void of wit.

DINNER OF THE ALUMNI OF THE UNIVERSITY MEDICAL COLLEGE.—The fifth annual dinner of the Alumni of the Medical Department of the University was given at Delmonico's on Thursday evening, Feb. 17th. The President of the Association, Dr. C. I. Pardee, presided. The Mayor of the city; Chancellor Crosby; D. Willis James, of the Council; Dr. Roosa, '60; Professor Markoe, of Columbia College; Professor Noyes, of Bellevue; Dr. George I. Fisher, class of '49, of Sing Sing; Dr. MacDonald, class of '70; Dr. Rush, of '76; Hon. Mr. Bailey; Dr. Wm. H. Thomson; Hon. Mr. Depew; Whitelaw Reid, Esq.; and Dr. William A. Hammond, of '48, responded to the regular toasts. The dinner was a large one, the alumni and guests filling the large room of Delmonico, and will long be remembered by those who were present as a happy assemblage.

POST-MORTEM KINDNESS.—In the course of an admirable editorial article on the above subject, in *The American Medical Weekly*, Dr. E. S. Gaillard says:

"I knew a physician who went through life with scarcely a word to cheer, encourage, and strengthen him. He was brave enough to endure in silence. He was accomplished, true, and skilful; charitable and kind; but no one ever told him so. He struggled bravely with poverty and adverse circumstances, but there was scarcely one to help him. Troubles thickened about him, but these were not told, and there were none who cared to inquire about them. He struggled always for the right, and to aid in maintaining what was just and true in his profession; but misunderstood, and his actions misinterpreted, he was frequently maligned and seldom supported. He toiled bravely on; a generous husband; a devoted father; a good neighbor; suffering from labor; worn with care; maintaining all the while his family, and adorning his profession; winning gradually a sure foothold and a reliable income. But suddenly he staggered under the load so long carried, and fell. After a brief illness he died. His brethren gathered at his funeral; they profusely decked his bier with the choicest flowers. They recorded before their profession and the public their appreciation of his talent and of his bravery. They praised his energy and devotion. They eulogized his endurance under trial, and his patience in his struggles. There was not a word of aspersion, of contumely, or of blame. Many spoke indignantly of the false charges that had been made against him, and of the unfair treatment that he had received. There was enough said and done then to have gladdened his whole life; to have blessed and made him contented and happy; to have rendered his rugged journey a living sweetness. There was enough of moral sunshine poured over that silent coffin to have made the inmate's life a bright and cloudless day. But it all came too late; the cold ear was now deaf; the once responsive eye forever closed; the heart that could have been gladdened was still; the hand could no longer feel the friendly grasp and be warmed by it. All was too late. It was the saddest of all manifestations, post-mortem kindness."

MEDICAL DEPARTMENT OF UNIVERSITY OF NEW YORK.—The Thirty-fifth Annual Commencement of this institution was held at the Academy of Music, on the evening of February 15th, at which time the Degree of Doctor of Medicine was conferred by Chancellor Crosby upon 133 graduates. Prizes were awarded to the following gentlemen: To Harry Bell Conrad, of New York, the Mott gold medal; to Alexander Dallas, of New York, the Mott silver medal; to Elbert C. Drake, of New York, the Mott bronze medal; to C. A. H. L. Von Randohn, of New York, Prof. Budd's prize, also Prof. Thomson's prize; to Wm. Howland Taylor, of Mass., Prof. Loomis's prize; to Edward Sanders, of New York, Prof. Arnold's prize, also Prof.

Roosa's prize; to Samuel Kohn, of New York, Prof. Weisse's prize; and to H. S. Norris, of New York, the prize established by Mr. James Bryce.

The Academy was filled to overflowing. The music was furnished by Grafulla. The address to the graduating class, delivered by Rev. Dr. Storrs, of Brooklyn, was brilliant and powerful, and received untiring attention. On this, our centennial year, the memory of the relation sustained by the medical profession to the nation at the time of its birth was revived, and the extent and importance of the work now before the class, as medical men and citizens, were eloquently set forth. It was maintained that the enthusiasts move the world, but that the only true enthusiasm is that which seeks truth, because it is truth; does good because it is good; and performs duty because of the love of duty. In this there is manifested an affection, and in the affection is the unfailing reward. Dr. George W. Chandler, a member of the graduating class, delivered the valedictory address, which was favorably received.

Army Medical Staff Rank.—The following is the memorial to be presented by the Committee of the American Medical Association.

To the Honorable Senate and House of Representatives of the United States, in Congress assembled:

The undersigned, a committee of the American Medical Association, respectfully represent that the existing laws do not, in the opinion of the association, accord to the medical corps of the army equality in rank with the other staff corps, or with the medical corps of the navy. The committee believe that the members of the medical profession throughout the United States share in this opinion, and that they earnestly desire that an increase in rank and pay be given to the medical officers of the army. A petition to this effect was presented to your honorable body during the last session of Congress. A report of the committee charged with that service was made to the American Medical Association at its meeting in Louisville in May last, and is herewith submitted. In accordance with the resolutions therewith adopted, the undersigned members of the committee, and in behalf of the medical profession of the United States, do earnestly entreat Congress to redress the grievances of the medical corps of the army, and to put it upon a permanent basis of respectability and usefulness. They beg leave to represent that this can only be done by providing that the officers of this corps shall hereafter receive a certain increase in rank in accordance with length of service.

And your petitioners will ever pray.

H. A. Johnson,
Chairman of the Committee.

The Ulster Overcoat is spoken of by the *Sanitary Record* (London) as "the *ne plus ultra* of convenience and comfort." It further says, and very correctly too, we think, "Its length, if not its style, should be adopted in all overcoats, which should reach to at least three or four inches below the knee for adequate protection against cold." This style of garment is quite popular with the medical profession, not only here, but everywhere else.

Health Physician of Knoxville.—Through the efforts of the Knox County Medical Society the aldermen of Knoxville have rescinded their former action abolishing the office of city physician for Knoxville, and have increased the salary of that gentleman. This is a good example for other societies in protecting the rights of their members, and using their influence against political trickery.

The Right of Druggists to Prescribe.—An action has recently been brought by the Apothecaries' Company against a chemist and druggist of High Street, Shadwell, to recover a penalty of £20, under the provisions of the Apothecaries' Act, for alleged infringement of that act, by practising as an apothecary without having obtained the necessary certificate from the company. The jury returned a verdict for the plaintiff. In Great Britain, at least, illegitimate counter-prescribing has received its death-blow.

The Title of Doctor of Medicine and the London College of Physicians.—A committee appointed to consider resolutions bearing upon the above, recently adopted the following: "That no fellow, member, or licentiate of the college is authorized or entitled, by virtue of any diploma or license of the college, to append to his name the title of Doctor of Medicine, or the initial letters M.D., or any other letters indicating that he is a graduate in medicine of a university, unless he has obtained a Degree in Medicine from a university legally entitled to confer such a degree, and which is recognized by the college." This will apparently end a long controversy on the subject.

Doctors and Newspapers.—Dr. A. G. Field, of Des Moines, Iowa, publishes an article with the above caption, in which he advocates the expediency of newspaper advertising. Some of our New York brethren are so well versed in this business that they can give Dr. Field a great many useful hints.

Royal College of Surgeons, Ireland.—It is intended to enlarge the museum and library of the Royal College of Surgeons, Ireland, at a cost of £5,000.

"Peculiar People."—Another of this religious sect has been indicted in England for refusing to call in aid, and thus probably preventing a death from whooping-cough. Our British cousins are certainly very practical people.

The Medical Society of District of Columbia has completed its second volume of transactions. It is made up for the most part of the reports of the stated meetings by the Secretary.

Acute Bronchocele in Pregnancy.—Dr. John B. Roberts, of Pennsylvania Hospital, Philadelphia, asks for accounts of cases of the above, attended with grave attacks of dyspnœa.

County Main Sewers in Aid of the Drainage of Villages and Small Towns.—Dr. A. O. Bayles contributes a very practical article on the above subject in the London *Sanitary Record*, January 15.

Scarlet Fever.—A gentleman of London has recently been fined for conveying his daughter, while suffering from scarlet fever, to an hospital in a public cab.

Weekly Bulletin of Medical Societies.

Monday, Feb. 28.—Medical Society of County of New York. Discussion of Dr. Otis's paper.

Tuesday, Feb. 29.—Alumni dinner of College of Physicians and Surgeons—(Sieghortner's, 32 Lafayette Place, 6 P.M.).

Wednesday, March 1.—Commencement of College of Physicians and Surgeons.

Thursday, March 2.—New York Academy of Medicine.

Friday, March 3.—N. Y. Medical Library Association. Dr. Beverley Robinson's report on Diseases of the Throat.

Original Communications.

DIPHTHERIA.

CONDENSED FROM LECTURES DELIVERED IN JEFFERSON MEDICAL COLLEGE, ON MAY 13TH, 17TH, 20TH, AND 24TH, 1875.

By J. SOLIS COHEN, M.D.,

LECTURER ON LARYNGOSCOPY AND DISEASES OF THE THROAT AND CHEST.

TREATMENT.

III.

If diphtheria is primarily or essentially a constitutional affection, its development, when once it has fairly attacked the organism, can no more be prevented than can the development of the contagious exanthemata, typhoid fever, and other specific diseases of like character. Seclusion from infection appears to be the only reliable means of prophylaxis. If removal from infected centres is impracticable, we must be content with advising avoidance of exposure to cold, inhalation of dust and other deleterious matters in the atmosphere, over-exercise of the voice, and everything whatever which may predispose to inflammation or catarrh of the nares, throat, and air-passages. At the same time care must be taken to keep the general system in its healthiest condition; and if there is occasion for the use of tonics, the tincture of the chloride of iron may be administered with great propriety.

Upon the appearance of any morbid secretions in the throat or nostrils, frequent and efficient cleansing should be instituted with washes, douches, or gargles of weak solutions of table salt or chlorate of potassium; and if there is direct exposure to infection, carbolic acid, salicylic acid, sulphurous acid, permanganate of potassium, the hyposulphites, and the like, may be judiciously substituted on account of their antagonistic action upon the development or propagation of low organisms.

The treatment to be instituted, once the pathological products have become manifest, will depend upon the views held as to the nature of the disease and its cause. Nutritive, supporting and stimulating treatment constitutionally, is now almost universally recognized as absolutely necessary; and depleting measures, even of the mildest character, are almost universally avoided. This unanimity would indicate that diphtheria is something more than the pseudo-membranous croup, which, if we credit the records in our textbooks, was formerly thought to require the use of antiphlogistic measures.

With regard to the treatment of the local manifestations, there is much less unanimity of opinion. Practitioners who regard diphtheria as chiefly a systemic disease are apt to consider local measures as useless and productive of fresh sources of injury. They will depend on systemic medication to the exclusion of specific or special local measures, unless we look upon the exhibition of emetics, expectorants, and the like, for the expulsion of accumulations in the air-passages, as local measures. Many eminent practitioners discard all local treatment whatever. Practitioners who believe the disease to be chiefly local in the first instance, will direct their efforts towards removal or destruction of the morbid products, and, if too late to accomplish this result, to the exhibition of local agents that dissolve or decompose them. Those who partake of both views will pursue a mixed treatment accordingly.

Although numbers of observers denounce topical treatment on the score of its uselessness in a systemic disease, its inefficiency to prevent subsequent deposits in the same locality, its liability to induce additional deposit upon surfaces which may be accidentally or unintentionally exposed to contact with the local remedy, the difficulty of its effectual application in certain instances, and the like, evidences of the efficacy of local interference have been too numerous to justify entire reprobation of the practice. Employed by Aretæus, centuries ago, and then reintroduced into practice by Van Swieten, and again by Bretonneau, it has been abandoned and resumed again and again. Some observers resort to the local action of caustic applications, with the view of arresting the extension of the membrane over unaffected structures, or effecting its entire destruction,—and chiefly on the theory that the main danger lies in the deposit; others hope to excite a substitutive healthy inflammation of the part which shall supersede the unhealthy specific process; others, again, hope to destroy the cryptogamia which are believed to be the initial cause of the deposit; and others hope to place the mucous membrane in a condition unfavorable for the propagation of these organisms.

As diphtheria is always serious, every case demands close attention, and frequent and careful examination, with the aid of all the resources at our disposal; and the treatment, to be at all effectual in hazardous cases, must be assiduous and free from vacillation. Topical applications, when resorted to, should be made by the medical attendant himself, or by a professional assistant fully competent, no matter how frequently they need to be repeated; and other local measures should be instituted under the personal superintendance of a well-instructed attendant. Many a patient is sacrificed to inefficient attention, a neglect that is only excusable in the country practitioner whose patients reside at distances so remote that it is impossible to secure them a proper amount of professional surveillance, and which is actually culpable when there are other physicians whose assistance can be enlisted if the regular adviser is unable by press of business to devote sufficient personal attention to his own patients.

Several objects must be kept prominently in view during the entire treatment. Chief among these is efficient sustenance of the patient, and the prompt discharge of the morbid products as they accumulate. If these two main indications can be fulfilled the patient can be carried safely through the disease. There is no specific, topical or constitutional, which can arrest the disease or prevent the evolution of the local manifestations, although there are agents which modify the process and diminish the virulence of the infection. A warm, equable temperature, an excess of humidity of the atmosphere, and free ventilation conduce to the comfort of the patient, and the facilitation of expectoration. Until the appearance of the exudation we may depend upon nutritive and tonic treatment, with thorough cleansing of mouth, throat, and nares; care being taken to disinfect the apartment and the house as far as practicable. This disinfection may be accomplished to some extent by the free use of solutions of carbolic acid exposed here and there, or sprayed about from time to time, and of sulphurous acid in spray, or in fumes from ignited sulphur; these agents being competent, in some instances, to destroy the germs which spread the infection, if they do not originate it.

Tincture of the chloride of iron is one of the most

valued remedies for internal administration. It is usually given in decided doses frequently repeated; from five to fifteen or twenty drops, according to the age and vigor of the patient, every second hour, hour, or half-hour. It is necessary to secure its action upon the blood and system as rapidly as possible. Its frequent deglutition likewise exerts a beneficial physical influence upon the morbid products with which it comes in contact; for, as will presently be stated, it is one of our most reliable agents for topical medication. I have no hesitation in commending the use of this remedy.

Quinia is much used as a tonic in diphtheria, as well as for its action upon the nervous system, and as an apyretic in fever. It may be combined with the tincture of iron in the form of the hydrochlorate, or, if that is not accessible, in the usual form of sulphate. It is given in decided doses until the buzzing in the ears or some other manifestation gives token that the system is under its influence, when the doses may be lessened and the intervals between them increased. I am not much in the habit of prescribing quinia in diphtheria, unless I see some special indication for its exhibition; but this practice is by no means to be construed into any absolute disparagement of its remedial agency.

Alcohol, in the form of some strong wine or brandy, is of great value as a stimulant. From half a drachm to half an ounce of brandy, or its substitute, according to the age of the patient, may be given every two or three hours, or more frequently; and its free administration should not be delayed after the earliest symptoms of loss of vigor are apparent. Its effect on the general condition of the patient will be the criterion for its continuance. When indicated and well borne it may be used freely, especially if efficient nourishment is difficult.

Carbonate of ammonium is a remedy of great value at special moments of sinking. A full dose at such periods will sometimes stimulate the patient during a short interval, which may be taken advantage of for the administration of the remedies in systematic use, or of emetics, or inhalations of lime, and the like, to facilitate the expulsion of accumulating secretions in the air-passages.

Chlorate of potassium is extensively used as an internal remedy, frequently in the form of chlorine mixture, which contains an equal number of grains of the salt and of drops of muriatic acid in simple or aromatic water, infusion of quassia, and the like, with the addition of some syrup if desirable. It is also given in the form of lozenges, containing a grain or more of the salt each, administered as frequently as may be necessary to introduce the desired quantity of the chlorate, usually from thirty grains to a drachm or so in the twenty-four hours. Though rarely prescribing chlorate of potassium with confidence, the lozenge is the mode of administration that I usually prefer, because the remedy is retained longer in contact with the affected parts, and thus has a better chance to exert a beneficial influence locally. I must remark, however, that I have rarely seen, even in slight cases, the remarkable results from this remedy which have followed its exhibition in the practice of many others; and though acknowledging its occasional usefulness, I am inclined to doubt its efficacy as a reliable remedy against the disease or against its local manifestation. Furthermore, its inordinate use may irritate the kidneys, a result to be avoided in view of the significance of albuminuria as an unfavorable manifestation.

Calomel, first employed in croupous affections by the illustrious Dr. Rush, of this city, is extensively used as an internal remedy to modify the condition of the blood and to prevent further exudation; some practitioners believing that the disposition to exudation is arrested as soon as the system is under the influence of the mercurial. It is given early in the disease, before the strength of the patient has become too much impaired, in doses of from one to three grains every second hour, hour, or half-hour, until there is evidence of its constitutional effect in the characteristic stools, or upon the gums, when it is discontinued or repeated at longer intervals as circumstances may dictate. Bretonneau and others have reported successful results from this treatment, even after the larynx and trachea had become implicated. Mercurial inunctions, a drachm of the usual ointment every hour, are sometimes employed in addition, to hasten the desired result. In infantile cases, with prominent cerebral symptoms, boring of the head into the pillow, and the like, I have seen excellent results from the internal use of calomel; but I would not recommend its employment otherwise, except at an early period, and in a vigorous subject, and would abandon it after a few doses, if there were no decided evidence of its usefulness.

Bretonneau felt induced to believe * that the action of calomel in modifying the pellicular inflammation was due to its insinuation into the larynx; and Jodin attributed much of the good effects of the internal administration of both calomel and chlorate of potassium to their mechanical action in passing over the deposits.

The alkaline carbonates of potassium and sodium, and the acetate of potassium, have been recommended for their influence on the disposition to exudation, and they are often exhibited in association with calomel. Large doses are said to be necessary; from fifteen grains to a drachm in the twenty-four hours to infants, and from one to three drachms daily to adults. I have no experience in their use in diphtheria.

Copaiba and cubeb have been highly recommended by Trideau, especially in the first and second stages of the affection. To adults he administers a dessert-spoonful of the syrup of copaiba every second hour, followed in the intermediate hours by fifteen grains of powdered cubeb in a tablespoonful of syrup. For children the dose is about one-half of this amount. These remedies are administered on the principle of their property in drying up sources of mucous secretions. Cubeb, more particularly, has received the commendation of many observers who have followed Trideau in its use. It is supposed that the elimination of these remedies by the respiratory tract enables them to exert a special topical influence on the bronchial mucous membrane.

The hyposulphite of soda, recommended by Dr. Tubbs, of Upwell, is sometimes used internally, in the hope that in its decomposition the system may be favorably subjected to the influence of sulphurous acid upon low organisms. It is administered in doses of from one to three grains to children, and from eight to ten grains to adults, repeated every three or four hours.

On similar grounds carbolic acid and salicylic acid have been given in diphtheria with asserted benefit. I have no experience to offer in this connection, but should not anticipate much from the internal use of antiseptics from quinine, through the list, to salicylic acid, as much larger amounts would be required to disinfect the mass of the tissues than it would be convenient or safe to administer.

Bromine has been used internally with much asserted

* Op. cit., 4th Memoir, p. 163.

success.* As will be mentioned later, it is a valuable remedy by inhalation. I have no experience with its internal administration. The dose is a drop or two of a solution, one grain to the ounce, given in sweetened water, and repeated every hour or so.

Iodine and many other remedies have been extolled for their constitutional influence on the disease, but it is hardly worth while to enter into their consideration, as they are not in frequent use.

Swollen and tender glands externally have been mentioned as frequent accompaniments of the earlier symptoms. Warm applications of cotton wadding, spongio-piline, or even actual cataplasms are frequently used to relieve suffering; and some cases are treated by mild inunctions with some innocuous ointment or grease, as lard, cold cream, olive oil, and the like. Care must be taken not to employ agents which may abrade the skin, on account of the danger of cutaneous infection, with its unfavorable effects. Some practitioners employ cold compresses, and even ice externally, but the practice is by no means devoid of injurious consequences, though often resorted to with impunity. If not promptly beneficial their use should be discontinued. Ice to the interior of the inflamed throat, on the contrary, is often a grateful and beneficial application, though condemned by some authors. I have always allowed my patients to take all the ice they craved, and have encouraged the frequent use of iced-water, water-ice, and ice-cream in small quantities at a time; and my impression is that the use of pellets of ice, allowed to dissolve in the mouth, is steadily gaining in favor.

We now come to consider the treatment in reference to the exudation itself.

The use of emetics is indicated, in children, if there be evidence of accumulation of secretions in the air-passages, in order to provoke their expectoration by the act of vomiting. The action of an emetic is to induce diaphoresis of the skin from the vascular relaxation which accompanies the act, and something of the same kind may be supposed to take place in the bronchial mucous membrane, thus facilitating the detachment of viscid or adherent secretions. The air-passages of infants are very tolerant of mucous accumulations, and therefore this point needs attention. It is an important matter to encourage cough, or to provoke it if necessary, whenever morbid products are accumulating in the air-passages. Adults are able to expectorate voluntarily, and the same indication for the emetic does not present. Alum, soon to be mentioned as one of the suitable local agents, is an excellent emetic in mild cases, and is unattended with the objectionable after-effects which sometimes follow the use of ipecacuanha, tartar-emetic, sulphate of copper, and the yellow sulphate of mercury, the four emetics in most use for the purpose. The recognition of the value of alum is due to the late Dr. Meigs, for many years Professor of Obstetrics in this college. It is administered in doses of a teaspoonful in an equal quantity of honey or molasses, and repeated in ten or fifteen minutes if the first dose is ineffectual. Should three or four doses fail to produce emesis, the other articles just mentioned may be substituted in proper doses. Considerable circumspection is requisite in the use of the tartar-emetic on account of its depressing effects. The hydrochlorate of apomorphia, a new remedy, has recently acquired great reputation as an emetic, on account of the promptness and certainty of its action and the almost entire absence of after-effects. It is usually administered by hypodermic injection, in doses of from one-thirtieth to one-tenth of a grain, and its effects are produced in a very few minutes. I have had no experience as yet with this agent, but mention it favorably on the authority of several reliable observers. Titillation of the base of the tongue is said to be sometimes effectual in inducing emesis in these instances. The emetic should be repeated at intervals of six or four hours, more or less, according to the indications. Emesis is by no means always requisite, nor should it be pushed too far.

Expectorants acting through the system are rarely of much use in diphtheria. The action of senega in rendering the exudation more fluid, and facilitating expectoration, is insisted on by Bretonneau,* and he was led to associate it, in doses of a few grains, with the calomel treatment, in cases where dryness of the mucous surfaces appeared to have been the principle obstacle to the expulsion of the false membranes. In case an expectorant is indicated, I think senega the most reliable agent that you can employ. Sanguinaria is used with considerable success by a number of practitioners in this city. A little carbonate of ammonium added to the senega is sometimes of advantage. I have seen chloride of ammonium answer a good purpose in some instances.

(To be continued.)

THE ELECTROLYTIC TREATMENT OF MALIGNANT TUMORS.

By WM. B. NEFTEL, M.D.,

NEW YORK.

My first case of a true cancer cured by electrolysis, which, as I can now add, has never been followed by a relapse, was published in this journal in 1869. Since then I have continued to study the clinical history and the histological nature of morbid growths and their electrolytic treatment, and published my researches in the fifty-seventh volume of Virchow's Archives, whence they have been reprinted in the leading medical journals of Germany, France, England, Italy, etc. At that time my principal object was merely to demonstrate that even the most malignant tumors (carcinoma, sarcoma, etc.) can be cured by electrolysis. I have since modified and improved the methods, the detailed description of which will appear in an English edition I am now preparing for publication. It seems to me, however, that without further delay I owe a brief reply to the inquiries of some of the numerous readers of THE MEDICAL RECORD, in the columns of which appeared my first preliminary notice upon the subject.

The final result of my researches can thus be summed up: "*The most malignant tumors (cancers, etc.), at a certain stage of their development can be radically cured by electrolysis employed according to certain methods.*"

As an illustration I mention three cases selected from a number of similar ones.

Mrs. H., wife of an experienced physician, forty three years old, married twenty years, and mother of three children, was formerly healthy, with the exception of dysmenorrhœa she had suffered from when a girl. After the birth of her first child she had an inflammatory swelling of the right mammary gland (puerperal mastitis), which, however, got well spontaneously. In April, 1869, she received a blow in the same breast, but the pain soon disappeared, and she thought no more of it until August, when she commenced feeling pain

* Ozanam, Comptes rendu de l'Acad. de Sci., 1856, p. 102.

* Op. cit., p. 165.

and discovered a hard lump that continued to grow slowly, and became adherent to the skin. The pain assumed a lancinating character and extended over the right arm.

I found the patient very much emaciated, anæmic, and cachectic-looking. The tumor was of the size of an orange, and adherent, the nipple was retracted, and the axillary glands somewhat indurated. The brother of the patient died from an epithelial cancer of the lower eyelid.

April 19, 1871, I performed the first electrolytic operation, with the assistance of Dr. Whitehead (formerly of New York, now of Denver), and of Dr. Harwell, the husband of the patient (of Waymanville, Upson County, Georgia). No fever or any other morbid reaction followed the operation; on the contrary, the general health of the patient commenced to improve very rapidly, and soon the appetite, sleep, and complexion became normal.

In the presence of the same physicians, April 28, May 2, and 6, I repeated the electrolytic operation, followed by the usual after-treatment described by me in Virchow's Archives. The tumor gradually diminished, then entirely disappeared, leaving no trace, and the patient returned home in an excellent condition of health. The patient and her husband have several times written to me that no relapse has taken place, that her general health continues to be excellent, and that she has gained flesh.

In his last letter, dated Jan. 1, 1876 (Waymanville, Georgia), Dr. Harwell writes to me: "I am happy to inform you that my wife is still living, in good health, and, I trust, permanently cured of the cancer that was so fast terminating her earthly pilgrimage. It will soon be five years since she was under your treatment, and as yet there is no symptom of a relapse."

The following case presents several points of interest besides the cure of the tumor.

Miss ——, about forty-three years old, of high social position, came under my care, Nov. 10, 1874, affected with scirrhus of the right breast and induration of the axillary glands. Her father died of a cancerous tumor on the neck, and her brother of consumption.

She suffered for a number of years from a most aggravated kind of dyspepsia, which allowed her to use only a few articles of food, and these in the smallest possible quantity. The slightest increase of, or variation in, the diet would cause such an amount of distress and suffering that the patient decided to undergo a slow process of starvation, as the only means of rendering life bearable. She arrived at this decision after having in vain tried all methods of treatment, and received the verdict of one of the most prominent physicians that her dyspepsia was incurable. A year and a half ago she noticed in the right breast a small nodule, which was slowly increasing in size, and for the removal of which she put herself under my care. I found the patient very much emaciated, in the right mammary gland one large nodule of irregular shape and of the size of a walnut, and, besides, several smaller ones; the axillary glands much enlarged and indurated. The patient kept in secrecy even from her nearest relations the existence of her tumor, and told me that she was prepared, if necessary, to suffer any amount of pain, provided the operation could be performed without the presence of any one. She would also take no anæsthetic, the effects of which she much dreaded.

Dec. 16, I performed the first operation by the improved method, which, however, I had to modify in accordance with the exceptional conditions and peculiarities of the case. The pain from the insertion of the needles was avoided by local anæsthesia, while Siemen's rheostate afforded the means of increasing gradually and slowly the current-intensity in a perfectly painless manner. One who has not witnessed such an operation can hardly imagine how the necrotic destruction of the tumor can be effected by a strong galvanic current without causing the slightest pain. The patient herself assisted me during the entirely painless operation, holding the inserted needles, etc., and after the operation walked home feeling quite comfortable. No febrile or any other reaction followed the operation, which I repeated in the same way three times, at intervals of several days, until the nodules disappeared, after which the usual after-treatment was commenced.

The most striking effect of the treatment was produced upon the dyspeptic symptoms, which have entirely disappeared, and the patient has not felt so well for many years. Her general health continues to be excellent, she has no dyspepsia, and is able to eat all kinds of food in the necessary quantity without any inconvenience.

She says she would have gladly undergone the same operation merely for the cure of her dyspepsia, were she not obliged to submit to it for the dispersion of the tumor.

Mrs. E., an intelligent and cultivated lady, about forty-nine, still menstruating, though irregularly, has borne six children, only two of whom are living. Her grandmother and three of her grandmother's sisters died of mammary cancers, her mother is supposed to have died of pulmonary consumption at the age of sixty-four, but as she also had a tumor in the hypogastric region, and a tumor or tumors in the abdominal cavity, it seems more plausible to assume that the alleged consumption was nothing but a secondary cancerous affection of the lungs. The patient was always in good health, except that in the winter of 1874 she occasionally felt a slight pain in the left breast, to which, however, she paid no attention, until in May, 1875, when she accidentally discovered in the breast a small lump, the size of a hickory nut, which grew so rapidly that in the course of two months it attained the size of a child's head. Her family physicians, Drs. Jones and Graham, of Charlotte, N. C., gentlemen of experience and high standing in the profession, declared the tumor to be a carcinoma of the most malignant kind; and as the axillary glands were already affected, and a surgical operation offered no hope of success, they advised the patient to go at once to New York and put herself under my care for electrolytic treatment.

I examined the patient July 17, 1875. She presented a somewhat cachectic appearance, but was otherwise healthy. The whole left mammary gland was transformed, or rather degenerated, into a large tumor, the size of an infant's head, irregular in shape and consistency. The tumor was adherent to the skin and subjacent tissues, the nipple indurated and retracted. In the axilla another tumor could be felt, the size of a hen's egg, and composed of a conglomeration of indurated and enlarged glands. The subcutaneous veins over the tumor were dilated. I could only corroborate Drs. Jones and Graham's diagnosis, and was very reluctant to undertake the case, as, according to the rules laid down by myself, the electrolytic treatment of malignant tumors is successful only as long as there are no deposits in internal organs; in other words, as long as the disease remains local. Taking into consideration the exceedingly rapid growth of the tumor (it was daily increasing under my observation), and

the affection of the axillary glands, the generalization of the disease seemed certain, and the treatment presented no hope of complete success. However, as a surgical operation was out of the question, and nothing else could save the patient, I resorted to the electrolytic treatment by my new method. I performed three electrolytic operations under the influence of an anæsthetic, and with the assistance of Drs. Castle, Hartt, and Robie, followed by the usual after-treatment, which, however, I had to modify, as will soon be described. The large tumor as well as the axillary tumor have entirely disappeared, the general health of the patient became excellent, and continues to be so, as she informs me in her last letter of Feb. 21, 1876: "I am getting on splendidly, have no pain at all, eat well, and sleep well, for all of which," etc., etc.

I select these three cases as belonging to different periods, since the introduction by me of the electrolytic treatment of malignant tumors. Though all undoubtedly malignant (cancerous), they differ, however, in the rapidity of their development and in the methods of treatment, the detailed account of which will be published in a separate monograph.

In conclusion, I may add that the electrolytic operations performed by me have never been followed by pyæmia, erysipelas, or any other accidental diseases, which so often complicate surgical operations. On the contrary, the general health of the patients commenced to improve rapidly, and they were not prevented by the treatment from pursuing their occupations and their social or household duties.

THE YELLOW OXIDE OF MERCURY IN PHLYCTENULAR KERATITIS.

By PETER A. CALLAN, M.D.,

NEW YORK CITY.

This form of corneal inflammation is essentially asthenic in character, following the exanthemata or any exhaustive disease, and often engendered by neglect of hygienic laws. Arlt denominates the disease scrofulosa, on account of its frequency amongst scrofulous subjects.

It is almost exclusively confined to subjects under fifteen years of age, and furnishes about four-fifths of all the eye cases amongst the children frequenting our eye hospitals and infirmaries.

Every practitioner has seen such cases, in which small vesicles or phlyctenules develop on the cornea proper or its limbus, almost heal, when fresh ones make their appearance; the former marking their course by whitish opacities or superficial ulcers very slow to heal, and accompanied by more or less intolerance of light. The *photophobia bears no relationship to the severity of the case*. The inflammation runs a course of weeks, usually months, getting nearly well, then relapsing; this repeats itself many times, finally wearing out the patience of both doctors and parents.

In the treatment of this form of keratitis, it is a *sine qua non* that the health of the patients be attended to, seeing that the little ones are not kept in dark or badly ventilated rooms, and when practicable sent into the fresh air, regulating diet, etc. It is only in this way, and in conjunction with the local treatment, that relapses can be prevented and the disease permanently cured.

In eye therapeutics the use of red and yellow oxide of mercury is nothing new. Twenty years ago Mackenzie recommended a powder of the former with sugar—one part to eight—to be blown on the eye for opacities of the cornea. Ten years ago Pagenstecher, of Wiesbaden, introduced a salve of the same proportions, using the yellow instead of the red oxide.

We have found the yellow oxide of mercury, mixed with the glycerinate of starch, one to six, or even one to four parts, in our hands prove a specific in phlyct. keratitis. The yellow is preferable to the red, on account of its not irritating so much, and lard is inferior to the glycerinate of starch as a vehicle.

In using the yellow oxide of mercury in such large proportions, certain advantages are to be derived over the ordinary methods of treatment, viz.: certainty of cure, great reduction of the percentages of relapsing cases, alleviation and disappearance of the intolerance of light, without the use of uncertain medication or surgical interference.

In using the ointment a quantity not exceeding half a pea should be put in at one time. The lids should be closed, and the eyeball gently rubbed so as to make the salve be distributed equally over the surfaces of cornea and conjunctiva. Omitting this it gravitates into the lower cul de sac, and in a small percentage of cases may cause a slight superficial abrasion. This abrasion quickly heals, however, if the treatment be omitted for one or two days. In the accompanying cases the treatment was not oftener than three times per week unless specified, and, as usual with such a class, not so frequently, the patients not being regular in attendance. In all cases that it is practicable, the application should *be made daily*, and, if possible, after the first few times intrusted to the parents, with appropriate instructions. It is well to continue treatment for two or three weeks after the apparent cure of the disease.

With regard to the use of s. atropia and hot fomentations, they may be necessary in the earlier stages of the inflammation, but in the later stages they are not imperative, particularly the hot water, which tends to produce a passive congestion, and retards rather than assists the disappearance of this asthenic disease.

We have used with unfailing success the yellow oxide in phlyct. keratitis during the last two years, and often in chronic cases of interstitial and vascular keratitis. Employed to remove chronic opacities of cornea, it will very frequently prove too irritating, causing slight conjunctival abrasions.

Dr. W. T. Bacon has given the yellow oxide of mercury in the proportions suggested a thorough trial at the New York Eye and Ear Infirmary, and has furnished me with the notes of some twenty odd cases, from which the following are averages of the whole number:

Mary W., æt. 8. Had keratitis for last year; first in right, then in left eye. Improved under treatment, but never well. Both eyes have opacities on cornea; one phlyct. on left cornea, two on cornea of right; considerable intolerance of light. Oct. 27, began treatment with salve of yellow oxide. Nov. 3, condition very much improved. Nov. 11, slight opacities mark the position of recent phlyct., and all injection cleared up. Intolerance of light entirely gone. Patient treated and kept under observation until Dec. 1st; discharged.

Wm. H., æt. 18 months. Since last May has had keratitis phlyct. of left eye. About August right eye began to have same trouble. Eyes irritable, cornea hazy; phlyctenula on cornea of right almost over pupil; left has a vesicle on limbus cornea, outer side. Much conjunctival injection of both eyes, with marked intolerance of light. Oct. 18, began use of yellow oxide, omitting all other treatment. Oct. 25, phlyc-to-

phobia has disappeared; all injection of conjunctiva removed. Haziness of cornea cleared up. Opacities remaining, and patient to be kept under treatment for some time longer.

Josie C., æt. 5. Last August first attack in left eye. A phlyctenula on lower and inner portion of limbus cornea, with band of conjunctival vessels running towards it. Intolerance of light moderate in degree. Oct. 18, began use of ointment. Nov. 3, marked improvement; no photophobia; phlyctenula almost healed. Patient failed to return until Nov. 12, when he was brought back with a relapse, great congestion of eyeball, and light very painful to the eye. Renewed the treatment. Nov. 15, saw patient; symptoms greatly alleviated. Nov. 19, cured.

Dan. K., æt. 4. Right eye affected since Sept. 30. Oct. 25, small ulcer of cornea, inner side, midway between pupil and limbus; very slow in healing. Used ointment for first time. Oct. 27, slight abrasion at cul-de-sac as a result of the application. Omitted yellow oxide, and touched the abraded surface with a 5 gr. sol. of nit. argenti. Nov. 1, ulcer has filled up and almost well. Patient failed to return.

Maggie O'N., æt. 9. Has been suffering with left eye since spring; eye would be almost well at times, and in a few days bad again. Large superficial ulcer on limbus cornea, lower and inner portion. Eyeball very much injected—*very little* intolerance of light. Oct. 20, began use of ointment, omitting all other medication. Oct. 27, injection nearly gone; no intolerance of light. Nov. 5, ulcer healed, leaving an opaque spot; no injection; treatment to be continued.

Mary R., æt. 15. Three years ago, first attack in left eye, following an operation for the destruction of the lachrymal canal of same side. Present attack dates back to Feb. 15, 1875. During all the intervening time the eye has never been well. Has but a slight amount of injection in the lower portion of the globe; not very marked photophobia. Has a phlyctenula on lower third of cornea. Oct. 1, has been intrusted with some of the ointment to use every day at home, with order to report at the expiration of a week. Returned cured. To continue for some time the treatment. In this case the constant flooding of the eye by tears is an active cause in keeping up the disease.

No. 29 W. 31st Street.

A CASE OF LEFT HEMIPLEGIA WITH APHASIA.

By S. HEMINGWAY, M.D.,

late resident physician epileptic and paralytic hospital.

The following is the history of a patient admitted to the Epileptic and Paralytic Hospital in the division to which Dr. E. G. Janeway was the Visiting Physician, and was seen by him on many occasions during the patient's stay in the institution.

The great rarity of lesion on the right side of the brain, associated with aphasia, is the reason why this history is presented.

Jane R., æt. 30, widow; occupation, seamstress; education fair, can read and write. Entered hospital Oct. 30, 1873. Family history good; says she always was a healthy woman till present illness. Admits having had a sore on genitals five years ago. Cicatrices are at present visible on forehead, which are probably a result of tubercular syphilide; says they came there five years ago. Her left eye shows the result of an old ophthalmia, which, it is supposed, was of gonorrhœal origin.

For two years past has had slight palpitation on exertion. Always used her right hand in her occupations.

Four months ago, one night when she was going to bed, she became suddenly speechless; there was no paralysis whatever. Next morning, on attempting to arise, found her left arm, leg, and side of face paralyzed, also with loss of sensation in those parts. Loss of speech was complete; and hearing, which before this was excellent, was now lost in left ear. Her tongue was only affected in sensation. She was not able to appreciate sweet substances placed on tongue. Sense of smell also lost. About one month after this attack, *i.e.*, three months ago, improvement began in speech, face, and lower extremity, and has continued since then. Upper extremity began to improve one month ago. Sphincters have not been affected.

Is a medium-sized woman, pretty well nourished. Mental faculties good, with exception of loss of memory, constituting well-marked amnesic aphasia. Is unable to recollect many words, names of objects, as hat, key, handkerchief, pencil, etc.; though she can readily repeat them on being told, she forgets them immediately afterwards. Is unable to read continuously, omitting words and giving up from inability to fix attention. On attempting to write the letters of the alphabet the result was A, B, C, D, D, S, G, H, I, but when the letters were told off to her she wrote them down easily. Partial paralysis remains on left side of face; cannot close eyelids tightly. Sensation is lost to a great extent in left side of face and in left nostril. Does not wince on the application of aqua ammonia to left nostril, nor does she wince when the conjunctiva on same side is touched with an irritant. Hearing poor on left side. Taste is impaired anteriorly and posteriorly on left side of tongue.

Dynamometer { left, 32 / right, 80 } outside circle.

Æsthesiometer is valueless on account of loss of sensation of reaction to pain. Does not wince on pinching arm, but does on palm of hand and tips of fingers. Perception delayed; takes about three seconds. Can raise arm to level of shoulder; a little stiff. Can flex and extend forearm and fingers, but slowly. Heart sounds normal. Walks without elasticity. Sensation in leg as in arm. Reflex action lessened. Electro-muscular contractility good.

Feb. 27th, 1874. Aphasia almost entirely disappeared. A little slowness in speaking.

Dynamometer { left, 60 / right, 80 } outside circle.

Sensation recovered in face, etc. Taste and smell all right again. Walks about as well as ever.

Treatment—Iodide of potassium internally, and applications of faradic current.

The Juniata Valley (Penn.) Medical Association is the title of a new organization, which held its first meeting in Huntingdon, Pa., Feb. 4, 1876. The following officers were elected: *President*, Dr. Roan Clark. *Vice-Presidents*, Dr. John B. Ross, of Blair, and Dr. D. P. Miller, of Huntingdon; Dr. J. I. Marks of Mifflin; Dr. D. M. Crawford, of Juniata; Dr. O. H. Orris, of Perry. *Recording Secretary*, Dr. A. B. Brumbaugh. *Corresponding Secretary*, Dr. A. Rothrock. *Treasurer*, Dr. W. M. Finley.

The next meeting will be held in Lloydsville, Blair Co., Pa., July 7, 1876.

Progress of Medical Science.

On the Connection of Epithelioma of the Tongue with Psoriasis of that Organ.—M. Trélat recently read an interesting paper on this subject before the *Société de Chirurgie*. He reported three cases, of which the first was a well-marked one of epithelioma which had been preceded by a very small patch of psoriasis. Surgical intervention proved useless, and the patient succumbed to the usual accidents of cancer of the tongue. The second tumor had started from a smoker's patch, which had existed a long time. The tumor was removed by the galvano-cautery, and microscopical examination showed the typical structure of epithelioma. In the third case, a tumor, divided into two lobes by a deep groove, corresponding to the median septum of the tongue, had developed from an old and rebellious patch of psoriasis. Although the usual signs of epithelioma, both functional and rational, were wanting, the tumor was removed by the galvano-cautery. Microscopical examination showed it to consist of the mucous membrane greatly thickened and traversed by bands of young epithelial cells, but there were no epithelial nests and no hypertrophied papillæ. Notwithstanding the absence of the ordinary signs of an epithelioma, and the almost negative results of the microscopical examination, M. Trélat considered the tumor an epithelioma in the earlier stages of evolution. Was the connection of psoriasis and epithelioma in these three cases simply a coincidence, or did the psoriasis become transformed into an epithelioma? The observations were still too limited in number to base a theory upon them, but M. Trélat believed that the lingual psoriasis should be held to have determined the development of the epithelioma by the continued irritation of the mucous tissue of the tongue. It may be remembered that Dr. Weir, at a meeting of the Dermatological Society of New York, on January 5th, 1875, related a case of *ichthyosis of the tongue* in a patient who had had syphilis, in which, after the failure of specific treatment, section of one of the tuberose masses showed the microscopic characters of epithelioma.—*Tribune Médicale*, Dec. 19th, 1875.

Comparison of the Open with the Antiseptic Treatment of Wounds.—Kroenlein has carefully compared the results of Volkmann and Thiersch in their antiseptic treatment of wounds, with those attained at the Zürich clinique by the open treatment in similar cases. He finds the results almost alike under both modes. For purposes of comparison he makes use of the major amputations of the extremities, fractures of the long bones treated conservatively, and extirpations of the mammæ, together with pyæmia, septicæmia and erysipelas. His tables are so arranged as to show distinctly the effect of other factors which influence the result, such as age, sex, the kind and seat of the amputation or wound, etc., apart from the mode of treatment. Thus, to give a few of his figures, of seventy amputations treated antiseptically, the mortality was thirty per cent.; of eighty-five treated in the open way, only twenty per cent. In regard to the great success of Volkmann in treating compound fractures of the leg, much greater than that under the open treatment at Zürich, the author thinks that an explanation of this difference is to be found in the advanced age of many of those treated at the latter place. In the cases of extirpation of the mamma the open treatment resulted much the more favorably. He concludes that neither method has proved capable of averting erysipelas, but that both have rendered rare the occurrence of pyæmia and septicæmia. Under the antiseptic treatment the time requisite for a cure is decidedly shorter, and the function of joints better preserved, owing to the frequent occurrence of primary union. He regards the caustic and toxic qualities of carbolic acid as of great disadvantage in the antiseptic method, a difficulty which the use of salicylic acid may avoid. Then this latter method is far more expensive than the other.—*Langenbeck's Archiv*, XIX. 1.—*Berl. klin. Woch.*, Dec. 6, 1875.

A Case of Ulcerative Endocarditis Involving the Pulmonary Artery.—The following case is reported by Drs. Lehmann and Van Deventer, of Amsterdam. A laboring man of 46 years was admitted to the hospital on March 21st, 1875, and the diagnosis was made of acute croupous pneumonia, in the stage of resolution, of the lower lobe of the right lung. He did well at first, but on April 2d he was found to have a pleuritic effusion on the right side also, and on the thirteenth thoracentesis was performed with Dieulafoy's aspirator, and some twenty-one ounces of pus were withdrawn. This operation had to be repeated on the seventeenth of April, but after drawing about five ounces of pus no more could be obtained, although there was evidently more within the thorax. The patient died on the 21st, with symptoms of collapse, but at no time showed any symptoms whatever of cardiac disease. At the autopsy the right lung was found compressed upwards, and the space between it and the diaphragm occupied by a collection of some 42 ounces of pus, divided into two compartments by a vertical partition formed of the thickened pleura, which accounted for the imperfect results of the tapping. The calibre of the pulmonary artery was found to contain five fibrinous clots, adhering to the semilunar valves, which latter, though retaining their normal form, were ulcerated on their free surfaces and edges, so as to be almost transparent. There were also similar ulcerations on the lining membrane of the artery near the valves. There were no thrombi in the lungs. Under the microscope the diseased valves were found studded with small lymphoid cells of the size and form of pus cells, and the same was true of the ulcerated surfaces, where, too, the cells were lodged between fibrinous threads, which were immediately connected with the coagula mentioned. At the points of attachment of these coagula, and also in and among the pus cells, were everywhere to be seen accumulations of round, highly refracting, generally punctiform bodies, wholly destitute of motion, and which remained almost unaffected by various reagents. These particles were also found in the blood of the heart, in the pus from the chest, and in the canaliculi of the kidneys. The authors express their opinion that the empyema was the primary disease, but confess themselves utterly unable to determine whether the minute bodies they found were vegetable organisms or merely the detritus of tissue. This latter question, the very unusual occurrence of ulcerative endocarditis on the right side of the heart, and the absence of any symptoms indicating its presence during life, make this case worthy of interest.—*Berl. klin. Woch.*, Dec. 6, 1875.

Sudden Death with Albuminous Expectoration following Thoracentesis.—M. Oulmont reports the following case from the Hôpital Lariboisière. A female patient was admitted on the sixth day of an acute articular rheumatism. Auscultation revealed a

double endocardial murmur, most distinct at the apex of the heart. She improved steadily for nine days, but on the tenth day had a relapse of the articular pains, attended by effusion into both pleuræ. Eight days afterwards she was suddenly seized with a violent attack of palpitation and dyspnœa. The effusion was the same posteriorly, but anteriorly on the left side, there was dulness and friction sounds extended up to the clavicle. In view of the imminent asphyxia, thoracentesis was performed on the left side, but only 6½ oz. of a clear yellowish fluid were removed; false membranes constantly interrupting the escape of the fluid. A second puncture was made in the axillary line, but only a few drops of fluid escaped. Although the auscultatory signs were unaltered, the patient felt somewhat relieved. Five minutes later, however, she was seized with violent dyspnœa, and her mouth filled with an abundant, frothy, yellowish liquid. She spat up a spittoon and a half full of this fluid, and died twenty minutes after the operation. At the autopsy the borders of the mitral valve were found to be thickened. The left pleura was covered with soft false membranes, one-fifth of an inch in thickness, and contained about half a pint of yellowish fluid. There was atelectasis of the lower borders of both lungs posteriorly, but they were otherwise healthy. There were no traces of puncture of the lung, and no frothy fluid in the bronchi. What was death due to? Evidently not to perforation, nor to congestion and œdema, nor to absorption of the fluid left in the pleura. M. Raynaud has reported a case of instantaneous death following a simple incision of the skin, and he thinks it possible that death, in this case, was due to a reflex irritation produced by the puncture of the trocar acting on the pneumogastrics through the medulla. The irritation, however, must have acted slowly, and have produced an effect analogous to that neuro-paralytic œdema which is produced in animals by division of pneumogastrics.

In discussing a case similar to the above before the *Société Médicale des Hôpitaux*, M. Marrotte attributed the sudden death to syncope dependent on the sitting position in which the patient was at the moment. He did not overlook the influence of the derivation of blood resulting from the evacuation of a large amount of fluid, but attached more importance to the sitting position, for he had seen a certain number of typhous patients, in the stage of convalescence, who had died while sitting up. From this circumstance he deduced the rule never to perform thoracentesis with the patient in a sitting position.—*France Médicale*, Dec. 8th, 1875, and *Mouvement Médical*, Dec. 25, 1875.

Petroleum in the Treatment of Skin Diseases.—Dr. Maccormac recommends petroleum for porrigo and favus in preference to other remedies. The plan of treatment, so far as the scalp is concerned, is to clip or shave the hair closely. One part of petroleum is to be added to two of lard. This ointment should be applied gently but thoroughly once or twice a day. In cases that have been neglected, poultices of bread or linseed meal should be used before applying the ointment. After the application, a piece of dry, soft linen rag may be laid on, and over all a clean linen cap. Before the next application of the ointment, the head must be cleansed with black or fish soap, and warm water.—*The Practitioner*, October, 1875.

Suppuration of the Lachrymal Sacs in Infants.—Mr. Hutchinson, speaking of this uncommon affection, says he has only seen two cases. In both of these, pressure over the lachrymal sacs caused the pus to regurgitate freely through the canaliculi. There was no redness, or evidence of inflammation. He found it difficult to form any conjecture as to the cause of the symptoms in these two cases. Both the children were quite healthy; in both it occurred so immediately after birth, that it was difficult to suspect any exposure to cold, and in both it occurred on each side, making the action of any accidental cause improbable.—*The Lancet*, December 18, 1875.

On the Anatomy of the Position and Changes in Position of the Uterus.—Pausch of Kiel calls attention to the want of agreement between the results of anatomical investigation and the views of gynecologists on these matters, the difficulty being referable largely to the effect of post-mortem changes in the position of the uterus. He considers the delineations of Kohlrausch the best that have been produced. They were made from alcoholic preparations, with the bladder and rectum filled with cotton. In effecting the post-mortem changes he attributes great influence to the disappearance of the swelling of all the tissues and of the contents of the vessels, to the contraction of the muscles, and to the action of gravity, which now comes into play. Intra-abdominal pressure must also be considered; and as these changes increase with the lapse of time, it is important that the investigation, to be accurate, should be made early. As the filling of the bladder and rectum lead to changes in the position of the uterus, either in part or as a whole, there is no "normal" position for it, but only a "medium" one. The attachments of the uterus, he says, consist of its connection with the wall of the vagina and with the circum-cervical layer of connective tissue bounded behind by the abdominal cavity, in front by the bladder, and laterally losing itself in the connective tissue of the pelvis. Then there are the well-known duplicatures of the peritoneum, and under them he describes two strands of muscular fibres arching from the broad ligaments to the pelvic wall in front or behind.—*Arch. für Anat. Phys. u. wiss. Med.*, 1874, 6, p. 702.—*Schmidt's Jahrb.*, 168, II., 1875.

Atrophy of the Optic Nerve in Pott's Disease.—M. Abadie has observed this atrophy in a patient suffering from Pott's disease at the level of the first lumbar vertebra, where the first symptoms had coincided with the ocular troubles. He regards it as probable that in a certain number of cases, atrophy of the optic nerve, without apparent cause, may be symptomatic of a Pott's disease, of which the symptoms referable to the spine and cord have disappeared some time before. The ocular complications have not been more frequently observed, partly because the osseous lesions have disappeared at the time the former were discovered, partly because Pott's disease only induces them when it is located at certain special points, as at the level of the cilio-spinal centre. The above fact is therefore held to indicate the propriety, in cases of atrophy of the optic nerve, of examining the spine, and of applying appropriate treatment to the angular curvature, if any should be found.—*Journal de Méd. et de Chir.*, Jan., 1876.

Probable Intussusception Reduced by Injection with the Body Inverted.—This method was put in use by Mr. Waren Tay in an infant seven months old, where the intussusception had been in existence thirty hours. As much warm water as possible was injected, while the child was held up by the feet. The relief was immediate, and the tumor which before was felt per rectum, disappeared entirely. Mr. Hutchinson has repeatedly insisted, that it is not material whether air or water be injected, but it is very important to have the patient held up by the heels.—*The Lancet*, January 1, 1876.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

THE ARMY MEDICAL SERVICE.

The medical staff of our own army is not alone in its discontent concerning increase of rank and pay. In Great Britain, for instance, the dissatisfaction concerning the privileges of the line officers compared with those of the medical staff is so great, that it is almost impossible to obtain candidates for the entrance examination. Indeed, the government has been, for this reason, compelled to postpone such examinations, and the vacancies created by death and promotion are not likely to be filled by first-class men. For a short period after 1858 that service seemed to be quite popular with the profession, as it held out reasonable hopes of fair remuneration for the time being and a promise of future increase in rank and pay, commensurate with length of time in the army, increase of experience and consequent increase in usefulness. Soon, however, the jealousy of the line manifested itself in many curtailments of rights, positive and relative, until the army surgeon virtually finds himself in the same position as he was before any of the reforms, which he had so long asked for, had been initiated.

The *London Lancet*, in speaking of the drawbacks of this branch of the service, refers particularly to the slowness of promotion, and the almost certain prospect "that a young man, however able, industrious, or ambitious, would have to retire at the end of twenty-five years' service—most of it foreign—with the mere rank and pay of surgeon-major." All this time the training for the medical profession is becoming more difficult and expensive, at the same time, by a recent warrant, the work of the medical officer is increased, and the pay is diminished. This, then, is the state of affairs in Great Britain, and an effort is to be made during the present meeting of Parliament to remedy the difficulty by appropriate legislation.

In Germany a similar dissatisfaction exists regarding the vexed question of increased rank and pay, appeals for relief are unheeded, and there is great difficulty in filling the lower grades with competent men. The medical department of the Prussian army was considered in advance of those of all other countries in the perfection of its system of appointment, promotion, and pecuniary compensation; but the strides of improvement which have been taken, especially during the past few years, are so effectually checked, that only such as are compelled to do so stay in the service. It appears that the Imperial Government has not made good its promise to fulfil all the conditions of the army warrant of 1873, the consequence of which has been a considerable amount of pecuniary stinting in the lower grades. The war minister, yielding to the pressure of professional sentiment, asked for increase of funds, but with no avail, and the vacancies still exist. The latter condition of affairs obtains in our own army, and for a like reason. The same disposition to ignore the actual value of medical services is so strikingly apparent here, that no young medical man ever thinks of remaining in the army more than the few years which may be necessary to bridge over the threatened impecuniosity of his early professional career. And this will continue to be the case so long as the authorities refuse to recognize our claims, and decline to offer to us adequate inducement for faithful and efficient services.

At a time when special and renewed efforts are made to secure the passage of a new law for the relief of our own army medical staff, this subject of medical army bills becomes a matter of special interest.

Although the experiences across the water are not very encouraging, we have reason to believe, in view of the reasonableness of our demands, that the petition will be granted. And even then our medical staff will be so much below that of any other country, in the matter of rank and pay, that their complaints should be viewed in the light of arguments to prove what we ought to have, rather than what we now ask. If, however, the bill does not pass, the trouble of vacancies on the medical staff will not only continue to exist, but will increase, for the simple reason that the profession will abandon the idea of ever obtaining their rights by legislation, and will leave the army to take care of itself. It may after all be possible that such a state of things will occur before justice is done. But we are for the present, at least, willing to wait and to hope.

THE CARE OF OUR HOSPITAL PATIENTS.

The Committee of the State's Charity Association has published its annual report, based upon observations made concerning the care of the sick poor at Bellevue Hospital. Although the general condition of this institution is far from what it should be, and although many complaints of shortcoming are made, it is a matter of surprise that they are not even greater in number and more difficult, under the present system

of management, to remedy. The want of the proper number of surgical instruments and surgical appliances is certainly a very grave one, and for which there can be no possible excuse. Neither is there any good reason why the patients should not have a suitable amount of clothing, intelligent and efficient nursing, or a proper supply of substantial and nourishing food. The want of soap forms a very just ground for censure of the authorities, and shows as much as any apparently trivial matter can, the lack of forethought as to suitable provision of necessaries. But, taking everything into account, we are glad to find that it is no worse. With no desire, in the face of the facts, stated and vouched for, by the Committee, to offer any excuse for negligence in the discharge of sacred trusts, there are, however, many circumstances to be taken into account when we view the subject of management of this institution in a strictly impartial light. In the first place the Commissioners are a part of a political machinery which must be in the interest of patronage to party; consequently many, if not all, of the appointments of superintendents, orderlies, and nurses must be of a political character. Although this in itself is an evil, it can never be remedied short of a total abolishment of the whole system. In the second place, the funds appropriated to the support of the institution, allowing that they are judiciously and honestly employed, are limited, and the Board have to measure the expenditures accordingly. The greater or lesser quantity of this appropriation has an important bearing upon the quantity and quality of the food furnished, as well as other necessities. The food may not come up to the standard of fitness demanded by a committee of gentlemen and ladies accustomed to the luxuries of good living, but must nevertheless be regulated by the price *per capita*, which is so arbitrarily regulated by a certain limited amount of money. Not very long ago this vexed question was pretty thoroughly discussed by the Board, when it was determined to shift the responsibility of constructing a general diet table upon a medical gentleman, a member of the medical staff, whose fitness for assuming such a responsibility was unquestioned. The result, as claimed by the Commissioners, is that as nutritious, varied, and substantial diet is allowed the patients as can be obtained anywhere for the amount of money expended. If the full amount of this special appropriation is honestly expended, we see no particular reason to complain. Until the contrary is proved by the Committee, the responsibility of any neglect in this particular must rest upon the authority which fixes the price. Again, we must take into consideration the fact that the majority of the patients being paupers, they are not accustomed, even in health, to what people in the higher grades regard as absolute necessities.

In regard to the matter of so-called extras for those who are very sick, it is impossible to offer any excuse for not heeding the orders of the attending physician. If a limited amount of money is allowed for food in general, there should be enough of good management and consistent economy to enable the hospital authorities to set apart a so-called hospital fund to meet the exigencies which are so constant and so pressing in an institution of this size. This has been over and over again proved to be practicable during our late war, in the management of the military hospitals.

INFECTIOUS DISEASES IN SCHOOLS.

Our English contemporaries are much interested in the discussion of the proper means of preventing the spread of those infectious diseases among school children which are obscure in their invasion, mild in their progress, and variable as to the time when the danger of propagation is past. Whooping-cough being a disease of this class, and being at the time epidemic in Great Britain, a great deal is said about it in connection with practical epidemiology. To prove, however, the difficulty in the way of preventing the contagion, a correspondent of *The Lancet* states, that while health officer during a recent epidemic of whooping-cough, he issued a circular to the various schoolmasters and schoolmistresses, requesting them to have all children suffering, or suspected of suffering, placed upon the sick list and isolated. At that very time, one of the children of that gentleman was suffering from the disease, and was running about at large, entirely unsuspected. In fact, it was only when this child's brothers and sisters contracted it from him that the existence of the affection was recognized. Of course, nothing can be done in a practical way to prevent the spread of contagion under such circumstances of insidiousness of attack, but in the more pronounced cases some effort, at least, can possibly be made to isolate all those children known to have been exposed. At best, however, it is a problem for practical sanitarians, and the discussion which it is likely to receive may yet end in some practical results.

The Albany Medical College, Reorganization of the Faculty.—The following gentlemen have been appointed to the professorships named in the above institution:

S. Oakley Vanderpoel, M.D., Professor of Theory and Practice and Clinical Medicine; John V. Lansing, M.D., Professor of Materia Medica and Clinical Medicine; John Swinburne, M.D., Clinical Surgery; Albert Van Derveer, M.D., Surgery; John V. P. Quackenbush, M.D., Obstetrics; Samuel B. Ward, M.D., Surgery; Jacob S. Mosher, M.D., Hygiene and Medical Jurisprudence; Lewis Balch, M.D., Anatomy; Maurice Perkins, M.D., Chemistry; John P. Gray, M.D., of Utica, Mental Diseases; Edward B. Hun, M.D., Nervous Diseases; William Hailes, M.D., Anatomy, Histology, and Pathological Anatomy; George T. Stevens, M.D., Diseases of the Ear; J. P. Boyd, Jr., M.D., Diseases of Women and Children; Cyrus Merrill, M.D., Diseases of the Eye; Willis G. Tucker, M.D., Chemistry; Henry March, M.D., Curator, etc.

Reviews and Notices of Books.

PRINCIPLES OF HUMAN PHYSIOLOGY. By WILLIAM B. CARPENTER, M.D., F.R.S., F.G.S., F.L.S., etc. Edited by HENRY POWER, M.B., London, F.R.C.S. Eighth Edition. Philadelphia: LINDSAY & BLAKISTON, 1876. 8vo, pp. 1176.

THE first noticeable feature of this work is its immense size and its unwieldy shape; but the reader, although he would much rather have one volume in two, as two in one, is quite willing to overlook the forethought of the publishers, in consideration of the great amount of varied information to be found between the covers. Although, as the editor justly expresses it, it is impossible to give more than an outline of the more important results of recent research, the work itself, in regard to the faithfulness with which this outline has been presented, may be considered a skeleton cyclopædia of the science. The principal results of the numerous physiological researches which have taken place during the past five years are faithfully and comprehensively recorded, leaving nothing to be desired by one who wishes for a thoroughly trustworthy book of reference. These remarks apply with equal force to the recent improvements in microscopy in its application to the examination of tissues, as well as to the philosophical interpretation of the various complex functions of the human organism. The relations of these are not only explained in a practical manner, but their bearing upon pathological anatomy are considered with a faithful minuteness worthy of the highest praise. The new methods of making microscopic sections are particularly commendable in this connection. The microscopic anatomy of the different organs of the body and their functions are very elaborately considered, while many of the descriptions given are rendered more lucid by elegant wood-cuts. This is all that can be said in praise of the work in a general way. To the practitioner it is of the utmost value as a work of reference, for in it he will find all that he cares to know concerning the structure and functions of the body, and to the student who may be more particularly devoted to this particular branch, it is indispensable. We have experienced the greatest satisfaction in the perusal of certain chapters in this volume, and taking these as indices of the whole work we cannot say too much in its favor.

THE BODY AND ITS AILMENTS. A Hand-book of Familiar Directions, etc., for Care and Medical Aid in the more usual Complaints and Injuries of Adults and Children, etc. By GEO. H. NAPHEYS, A.M., M.D. Philadelphia: H. C. WATTS & Co. 1876.

THIS is a book written for the people, and will doubtless do a considerable amount of good in the way of general enlightenment upon medical subjects. There is one thing in its favor which we cannot say in general of works of its class, and that is, it does not endeavor to make the layman a self-prescriber. In the effort to give the most information for the money, the author occasionally outsteps the bounds of discretion in advising his readers concerning some of the operations in minor surgery, which are often difficult in the hands of experts. This will prove no fault in the work if the layman, in his presumption of self-knowledge, does not abuse the privilege of judging for himself when and how any even a simple remedy is to be applied.

ANNUAL REPORTS ON DISEASES OF THE CHEST, under the direction of HORACE DOBELL, M.D., Consulting Physician to the Royal Hospital for Diseases of the Chest, etc., assisted by DRS. ADOLPHE WAHLTUCH and R. SHINGLETON SMITH. Vol. I., June 1, 1871, to June 1, 1875. London: SMITH, ELDER & Co., 1875. 8vo, pp. 328.

THIS is the first volume of a series which will be published yearly, under the supervision of Dr. Dobell, giving a comprehensive, discriminate, and practical digest of progress in the treatment of chest diseases throughout the world. The editor has given evidence of great care in the selection of his extracts, and has amply availed himself of his extraordinary facilities for gathering information on this subject of his report from all quarters of the globe.

Reports of Societies.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, February 9, 1876.

DR. CHAS. K. BRIDDON, PRESIDENT, IN THE CHAIR.

URÆMIA AS A CAUSE OF DYSPNŒA, ETC.

DR. JACOBI presented specimens of the kidney, spleen, and portions of the respiratory apparatus, removed from a female patient of Bellevue Hospital. She was twenty-four years of age, a hard drinker, and had lived a very irregular life. Last November she had a miscarriage at the seventh month, which confined her to bed for about ten days. Nothing of any importance, however, could be learned concerning the symptoms from which she suffered on admission. She stated that she had a "cold" for ten days, and that three days before admission she lost her voice and began to suffer from dyspnœa. Examination of the lungs gave only negative results. Respiration was 26–30; pulse, 120–140; temperature by vagina, 99¼°; extremities cold. Dr. Jacobi saw the patient for the first time the day after her admission, February 5th. At that time she was aphonic, and was suffering from dyspnœa. The latter was of a twofold character: in the first place showing all the signs of laryngeal obstruction, at the same time the frequency of the respirations pointing to an abnormal condition of the lungs. On careful examination of the latter organs, there were evidences here and there of broncho-pneumonia. In looking for the cause of the laryngeal trouble, it was found that the tongue and pharynx presented a very unnatural appearance. The former was red, but not denuded of epithelium, was dry and hard, showed a number of elevated papillæ, and a number of well-defined grooves between. The pharynx was in about the same condition. Altogether, the parts presented a scaly appearance, similar to the condition of psoriasis on the external surface. Introducing the finger into the throat, the epiglottis was found stiff, hard, and thick, being more or less immovable during respiration. The larynx appeared to be in the same condition as the tongue. It was thought that the disease extended even beyond this point, and afforded an instance of a rare affection of the air-passages, characterized by an epithelial growth in the form of scabs, which sometimes necessitated operation for the dyspnœa which it occasioned. The diagnosis in a general way, however, was pharyngitis, laryngitis, tra-

cheitis, and broncho-pneumonia. Laryngotomy or tracheotomy was not advised in consequence of the lung complication, but the dyspnœa increasing it was considered imperative to open the larynx, and the operation was performed by Dr. Welch, house-physician, with temporary relief. She soon after grew worse again, and died February 6th.

The tongue, epiglottis, larynx, trachea, and upper bronchi, having been preserved in fluid, did not, of course, show the dryness noticed during life, but throughout their whole extent they were hyperæmic. The muciparous follicles of the trachea were somewhat swollen. Although there was some thickening in the air-passages, there was not enough to account for the dyspnœa. After death, there was found a certain amount of œdema of the lung, due probably to her dying condition. Dr. Jacobi believed that the dyspnœa had been due to a large amount of blood-vessel dilatation, which partly disappeared after death. Besides being œdematous, the lungs presented evidences of lobular condensation. The spleen was enlarged and lobulated. The principal interest, however, centred in the kidneys. The urine had not been examined during life, but the kidneys were in a condition of disease which had undoubtedly existed for a long time. Both organs were in a state of advanced nephritis, and contained abscesses. In regard to the question of diagnosis, the latter specimens were of interest in proving that the original cause of the congestion in the mucous tract was not appreciated during the patient's life.

DRYNESS OF MOUTH IN BRIGHT'S DISEASE.

Dr. Seguin remarked that Dr. Draper had called his attention to the fact that an unnatural dryness of the mouth and throat were very significant symptoms of chronic Bright's disease. In a number of instances he had been able to test the value of these signs.

Dr. Jacobi stated that the observation was undoubtedly correct, and that the case under consideration was an example of the sort. In answer to a question from Dr. Loomis, he remarked that the broncho-pneumonia could be explained by the want of air in the lungs reducing the pressure upon the blood-vessels, and in its turn inviting congestion and inflammation, but he believed that the œdema was simply a result of the dying condition.

DIPHTHERIA.

Dr. Lewis Smith presented the air-passages of a child aged six years, who had died of diphtheria, Feb. 7th. This patient had a brother three years of age who was attacked with the disease at the same time, and in the same way. Both had dyspnœa, hoarseness, and loss of voice, and in neither were there any signs of pseudo-membrane in the fauces. The temperature in each was about 100° F., pulse 95, and in the beginning (Feb. 2) no albumen nor casts were found in the urine. Both were able to run around, and the only symptoms of trouble were those belonging to laryngeal obstruction. Quinine was ordered for both children, three grains every two hours for the older, and half that quantity for the younger. The latter child, however, was exceedingly obstinate, and the medicine could be given only at very long and irregular intervals, and practically speaking it was without any treatment whatsoever. His brother, six years old, was, on the contrary, very anxious to take his medicine, and submitted patiently to the persistent use of the vapor of lime water, by Codman and Shurtleff's (Boston) apparatus. On the second or third day of attendance a considerable amount of fibrinous exudation was expectorated, but the relief was only temporary, the dyspnœa returning, and continuing to increase until death occurred Feb. 7.

The urine was not albuminous until thirty-six hours before death. Although no casts were discovered, the urea was in great excess. The younger child, despite the lack of treatment, was living at the time of making the report, and was as obstinate as ever.

At the autopsy made by Dr. Satterthwaite the lungs were found in a semi-collapsed state. The pericardial sac contained two drachms of transparent serum. The surface of the heart was normal. There was a large, firm, white clot in the right ventricle, extending into the pulmonary artery. In the right auricle there was also a large, dark clot with light centre, and slightly adherent. The cavities of the left heart contained a moderate amount of blood, which had a "tarry" appearance. A small point of diphtheritic deposit, not more than two lines in diameter, was found upon the left tonsil. There was, however, a firm exudation covering every portion of the larynx and trachea, entirely enveloping and concealing the vocal cords. This exudation was traced down to the bifurcation, and along the bronchi, to the left side. The left lung was examined, but no membrane was found below the first bronchus, merely a thickening of the mucous membrane by injection. There were no signs of pneumonia in this lung, although some signs of pneumonia were found in the upper lobe of the opposite one. The case was one in which, in the opinion of Dr. Smith, tracheotomy might have been followed by recovery. The membrane in the trachea was too thick to be favorably affected by the spray.

Dr. Satterthwaite, by invitation of Dr. Smith, gave the following description of the lesions found in the right lung: The pseudo-membrane was traced until it gradually faded away in the bronchi of the third degree. Beyond that point the mucous membrane was injected, and somewhat thickened. The upper lobe was in a condition of pneumonia, as well as upper portion of lower lobe. The middle lobe was merely congested. The bronchial glands were enlarged to a considerable extent. In the upper portion of the air-passages, where the membrane was thick and adherent, it had an opaque, cheesy appearance, but lower down, where it was thinner and less adherent, it was more translucent.

The examinations of the spleen, kidneys, and lung-tissue were made in conjunction with Dr. Edward Curtis, a detailed report of which was promised.

A short discussion ensued in regard to the supposed antiseptic effect of quinine upon bacteria, the opinions expressed being decidedly in the negative.

MYOCARDITIS AND SYPHILIS.

Dr. Burchard presented a heart removed from a young man aged twenty-five years, who, for the past fifteen years, had been addicted to the excessive use of alcohol. Dr. Burchard was first called to see the patient November 29, who was at the time suffering from an attack of double pneumonia. The case progressed favorably, and resolution was taking place when, on the tenth day, he was seized with a chill, which ushered in a double acute pleurisy and pericarditis. A diagnosis of these conditions was made accordingly, and subsequently confirmed by Dr. Loomis, who was called in consultation. No particular points of interest marked the case until January 19, when the patient began to experience excessive dyspnœa and great deterioration of strength. Dr. Loomis again saw him, and at that time made the diagnosis

of myocarditis. During the last week in January the patient developed well-marked syphilide. The strength rapidly failed, the dyspnœa grew more and more urgent, and on Sunday evening, February 7, he died.

The autopsy revealed excessive effusion in both pleural cavities. The lungs were comparatively healthy, although compressed by the effusion. The pericardial sac contained an immense amount of serous effusion, and its surface covered with plastic effusion. The heart was enlarged and dilated, and the substance of its walls almost entirely replaced by interstitial cellular growth. The liver was cirrhotic, and the kidneys enlarged and waxy. In some tubules there were immense deposits of uric acid crystals.

Dr. Loomis, in connection with the foregoing case, remarked that his experience had led him to believe that myocarditis was of much more frequent occurrence in connection with attacks of acute endocarditis and pericarditis than the statements of authorities would lead us to believe. In the present instance the diagnosis was very easy. The action of the heart was exceedingly feeble and labored, and the sounds peculiarly indistinct. He expressed the opinion that the train of chest symptoms was due to syphilitic infection, which did not declare itself until the eruption appeared, and after the lungs and heart had been involved.

SYPHILITIC AND SIMPLE PACHYMENINGITIS.

Dr. Seguin exhibited a section of the diseased dura mater, presented at the previous meeting by Dr. A. H. Smith, in order to prove not only that the diagnosis of gummy tumor was correct, but to exhibit some of the microscopic characters of the growth.

He presented a second specimen, likewise a section of the dura mater, the lesions of which were simply inflammatory in character. It was removed from a gentleman of Texas, who had been sent to Dr. Seguin by Dr. Hadden, on account of persistent headache. Five weeks before that time the patient had been exposed to a very hot sun, and although not suffering from any of the symptoms of sunstroke at the time, he subsequently was attacked with headache, from which he never entirely recovered. The headache was first seated in front, about the median line, over the region of the anterior fontanelle. It gradually extended backward in a symmetrical fashion until it ultimately became seated in the occiput and back of the neck. His pulse was 55, and regular. He was examined very carefully, and nothing was found upon which the diagnosis of organic disease of the brain could be based, and for the want of a better name the malady was called congestive headache. The patient went to the country, and, returning again in the fall, died. Dr. Seguin did not see him at the time, but had been informed that he had died comatose. There had been no difficulty of deglutition at any time, nor paralysis of any kind. Dr. Clymer, who had seen the case in consultation, was reported as non-committal in regards to a diagnosis.

The autopsy was made by Dr. Hadden, and showed a large clot over the convexities of both hemispheres on the external surface of the dura mater, and enveloped between it and another membrane of new formation. This latter was formed originally as the result of inflammation, was embryonic in character, and contained a large number of newly forming blood-channels. This condition of things was quite satisfactorily shown under the microscope to the members. The opinion was expressed that one of these blood channels had ruptured, producing the effusion in the substance of the new growth, giving the said effusion the gross appearances of a clot between two membranes.

Dr. Sell exhibited the cervix uteri removed by operation from a lady in Staten Island, the mother of four children, who had suffered for the last twelve years with all the distressing nervous symptoms which are associated with chronic enlargement of the organ. The operation was very satisfactorily performed by means of Dawson's battery. The patient promised to make a good recovery.

The Society then went into executive session.

Correspondence.

THE METRIC SYSTEM IN PRESCRIPTIONS.

To the Editor of The Medical Record.

Sir:—Can we not, at least those of us who are not too old to learn new things, make an effort to introduce the metric system into our prescriptions? Scientific men, the world over, here as elsewhere, adopt it for almost all measurements, whether of weight, length, or capacity. It has for several years been legalized in this country, and it is universally acknowledged by all who take the trouble to learn it to be the most satisfactory and convenient system ever proposed. Why then is it not adopted by a profession which claims to advance with the age? Simply because men are too indolent to spend a half hour in acquiring the few data which would enable them at a moment's notice to translate a grain and ounce prescription into a metric one. If they will simply remember that a *gramme* is about 15 grains, or the quarter of a drachm (Troy), and that 30 grammes weigh about an ounce (T.), the thing is done. A few weeks' practice will enable them to *think* in the metric system, and save the trouble of translating their ideas into it. Surely it is worth while to do this, and to get rid of our present system, in which we have, for instance, ounces of three different weights, viz., ℥ i. (av.) = 437.5 grains, f. ℥ i. = 455.56 grs., and ℥ i. (Troy) = 480 grs.

In writing a prescription by the metric system, the quantity of each ingredient is expressed, in multiples or fractions (decimal) of a common unit, which, of course, will be the gramme, thus:

GRAMMES.

℞ Hydrarg. proto-iod. . . . . 1.
Ext. lactucarii . . . . . 3.
M. Ft. pil. No. lx.

or

GRAMMES.

℞ Strychniæ sulph.,
Acidi arseniosi, āā 0.03
Quiniæ sulph. . . . . 2.
Ext. gentian. co. . . . . q. s.
M. Ft. pil. xxx.

I have adopted this plan myself, and would most seriously urge it upon the attention of those who have not travelled the bad old way so long, that a new departure is impossible.

Respectfully yours,
H. G. P.

George Green Gascoyen, F.R.C.S., one of the Surgeons of St. Mary's and Lock Hospitals, London, died in that city of pleuro-pneumonia, Jan. 23, in the forty-sixth year of his age.

NOVEL USE OF APOMORPHIA.

To the Editor of The Medical Record.]

Dear Sir:—The report of the following case may be interesting to your readers, so far at least as it suggests the value of the comparatively new remedy, apomorphia, in a class of cases in which I have not heard of its having been used. On the 30th of November, 1875, I was called to see a little boy, three years old, who had, two hours previously, accidentally swallowed a *biconvex lense-shaped tin whistle*. I found it lodged near the cardiac terminus of the œsophagus. The little fellow was suffering considerable pain, writhing his body when he attempted the act of deglutition, which act seemed irresistible every few seconds. A small quantity of bread and water was given him to ascertain whether the œsophagus might be completely occluded. He rejected it almost immediately, with no admixture of the stomach contents. I then administered hypodermically in his arm the one-twelfth ($\frac{1}{12}$) of a grain of apomorphia. In three minutes, by the watch, the emetic quality of the drug was manifested by pallor. He was then placed on a bed, flat on his belly, when, after three or four violent attempts, he in one heave emptied entirely the stomach, the whistle taking the lead, and ringing, as it fell in the basin, produced a most agreeable sound to the ears of the anxious mother, who before had but little faith in my expedient. The whistle measured $1\frac{3}{16}$ inches in diameter. The child, when seen an hour later, was bright and running about as well as ever.

Respectfully yours,

Ed. T. Robinson, M.D.

Richmond, Va., *Feb.* 21, 1876.

Obituary.

JAMES HINTON, M.R.C.S.

The death of the distinguished aurist and metaphysician, Mr. James Hinton, of London, was a very sad surprise to many of his friends in the United States, who did not know of his illness until the announcement was made in the London papers that he had died on the 16th of December, at St. Michael's, in the Azores. Mr. Hinton was about 52 years of age when he died. He had retired from practice about a year and a half before his death, for the purpose of engaging in some studies very congenial to his disposition. Among other subjects, the expression of force and truth by means of drawing and painting, was one to which he gave a great deal of time during the last few years of his life. He was a warm admirer of Constable and Turner, and he proposed to give a series of lectures to selected hearers during the next spring and autumn in New York, New Haven, and Cambridge, upon the study of art. Mr. Hinton's enthusiasm, on this and other subjects that interested him, was marked, and seldom failed to elicit responsive attention and sympathy from those who have enjoyed his entertaining conversations. Although Mr. Hinton was the author of several works on various subjects, "The Mystery of Pain: a Book for the Sorrowful," "Life in Nature," and was also a frequent contributor to the English magazines, he was chiefly known in this country as a successful aural surgeon, who contributed largely and well to the knowledge of the profession in otological science. His papers on the Pathology of the Ear, in Guy's Hospital Reports, the Appendix to Toynbee on the Ear, the article on Aural Disease in Holmes's Surgery, "Questions in Aural Surgery," and the Atlas of the Membrana Tympani, have made for him a reputation which perhaps will be as enduring as our language. Mr. Hinton studied medicine at St. Bartholomew's Hospital, in London, passing his examinations in 1848. He spent a year after this in Jamaica, having taken charge of a cargo of free negro laborers going from Sierra Leone to that island. He visited New Orleans, but embarked for England from that place without having been in the Northern States. He married in 1852, and practised as a surgeon in London for some years. In 1855 and 1856 he spent much time with Mr. Toynbee, and arranged his famous museum for the illustration of aural disease. Mr. Hinton retired from practice in 1858 or 1859, but returned again in 1862, and was appointed Aural Surgeon to Guy's Hospital, a position that he retained until his final retirement. He also succeeded to Mr. Toynbee's private practice in 1864. Mr. Hinton was looking forward with great interest to his proposed visit to America, where he had many admirers. The coming International Congress of Otologists was one of the attractions from which he promised himself much satisfaction, and of which he spoke in all his late letters to his friends on this side the water. Mr. Hinton was a man of decided religious convictions, believing firmly in a personal God. It is often thought, that in order to attain great success in any calling, there must be a preference for that above all others. Mr. Hinton's life is an evidence that a man who is constantly hoping for a day when he may forsake the avocation by which he earns his bread, for one more completely to his tastes, may yet be eminently successful in his enforced occupation. But we may not think that Mr. Hinton had a great distaste for his profession. He enjoyed even its laborious details, which he worked upon with industry, genius, and skill, and he acquired a large and lucrative practice, so that his waiting-rooms were among the most crowded of London; yet he always seemed to feel that there was a larger field for him than the practice of aural surgery. Just as he had well entered upon the prosecution of that, he passed into immortality.

Mrs. Hinton, two sons who are graduates of Cambridge and Oxford respectively, and one daughter survive Mr. Hinton. D. B. St. J. R.

CHANGES IN THE PUBLIC SERVICE.

Official List of Changes of Stations and Duties of Officers of the Medical Department United States Army, from Feb. 20th to Feb. 26th, 1876.

ARMY.

McKee, J. C., Surgeon.—Assigned to duty as Attending Surgeon at these Headquarters. S. O. 15, Department of California, Feb. 15, 1876.

Storrow, S. A., Assistant Surgeon.—Assigned to duty at the Presidio of San Francisco. S. O. 15, c. s., Department of California.

Williams, J. W., Assistant Surgeon.—Ordered before Army Medical Board, New York City, for examination for promotion; upon its completion, to accompany the first detachment of recruits to Department of Dakota, and until it is forwarded, assigned to temporary duty at Fort Columbus, N. Y. H. S. O. 34, A. G. O., Feb. 21, 1876.

Steinmetz, W. R., Assistant Surgeon.—Assigned to duty at Fort Wallace, Kansas. S. O. 28, Department of the Missouri, Feb. 16, 1876.

De Loffre, A. A., Assistant Surgeon.—Assigned to duty at Camp, near Cheyenne Agency, Indian Ty., S. O. 28, c. s., Department of the Missouri (now known as Fort Reno, Indian Ty.).

Medical Items and News.

Virchow.—A word about Virchow, and I will close. All in all, he is one of the most remarkable medical men I ever knew. His *personnel* is by no means striking. He is below the average German stature, of a dingy complexion, and with an impassioned expression; one fails to detect the depth of his researches in science, or the strong will or the cutting sarcasm which characterize him. An hour in the Pathologisches Institut easily demonstrates his accurate study in that part of medical science to which he has devoted the most hours of the best part of his eventful life. His political tenets, at variance with those of the chancellor of the empire, and in sympathy with that large radical party of Germany whose ideal may be seen in nearly every European government of to day, call it by whatever name you please, liberalism, radicalism, or conservatism, have developed an iron will and a bitter sarcasm which make him a species of terror to the government. In other ways is he remarkable. Always late at his lecture, and appearing now but twice a week, he has time enough, apparently, for the numerous demands made upon him. On the same day he is to be seen from nine to eleven A.M. in the Pathologisches Institut, demonstrating, with a vast array of material, cellular pathology; and from five to seven or eight P.M. in the Chamber of Deputies of Prussia, of which this week he was elected vice-president, over the nomination of his predecessor; later, hard at work in the Royal Geographical Society. Besides these official appointments he is chief editor of a popular journal of science, contributes occasionally an article to scientific bodies, and gives popular lectures in the winter. I have alluded to his life as an eventful one. It may not be generally known on our side of the water that in the revolution of 1848 he fought as a common soldier behind the trenches; that he was forced to abandon his professorship here on account of his political doctrines, and that he went to Würzburg, where the book of his life—the exposition of the cellular pathology — was written; that the government was obliged to recall him to his department in the university on account of the urgent demand of scientific men, who recognized his worth by the new book; that later Prince Bismarck challenged him to a duel, whose acceptance he had the courage to refuse; these and many other events of his life make Rudolph Virchow one of the most conspicuous men of the day in Germany. I am told that he regrets the comment not long ago made about him, that he was a severe critic as to the merits of other men. Virchow is poor, lives on the second flight, and complains that he cannot live as a gentleman of his standing should. —*Boston Medical and Surgical Journal, Letter from Berlin.*

Sulphite of Soda in Acute Dysentery.—Dr. John B. C. Gazzo, of Thebodeau, La Fourche Parish, La., wishes to call the attention of the profession to the virtues of sulphite of soda as a remedy for dysentery. He employs it in the following manner:—

℞	Soda sulphis	ʒ i.
	Acid salicylici	ʒ ij.
	Aquæ destil.	ʒ v.
	Syrup. rosa galli., U. S. P.,	
	Tinc. opii ℥ ll, āā	ʒ ss.
	Syrupi vanilla	ʒ i.

Misce. Fiat mistura.

The mixture was given in half tablespoonful doses, with an equal quantity of fresh milk every half hour. On account of its antiseptic and disinfectant properties he believes it can be employed in the form of an enema, and that it will not only destroy or annihilate the offensive, decayed, and putrid evacuations, but will also give considerable relief to the patient. The ordinary means for keeping up the circulation are also employed, such as stimulating antispasmodic liniments to the bowels and limbs. All of his cases did well.

Transactions of State Societies and Medical Journals.—The editor of the *Philadelphia Medical Times*, in noticing a number of volumes and pamphlets of State Transactions, says: "The amount of money which is yearly expended upon the printing of Transactions, of very little or no value, in the United States, must be enormous. It seems to us that it would be far better if every County or State Society would subscribe to some journal, to be supplied *en masse* to its members, printing nothing but the merest outline and business minutes, and turning into a useful channel the yearly sum now bestowed upon the typographer. A live weekly or bi-weekly journal would be a continual stream of light in many a place now sitting in darkness, and one year of trial would, we are convinced, render the present plan utterly obsolete. The success of the British Medical Association dates from the time when it created and furnished to its members the *British Medical Journal*. By massing numbers, it becomes possible to furnish a costly journal at a very small price per copy. Ten thousand subscriptions at two dollars make twenty thousand dollars, and would support a much more princely journal than could be furnished to three thousand subscribers at four dollars. The strength of numbers is nowhere more apparent than in journalistic enterprises, and, in spite of the enormous amount of journals published in the United States, the need of journalistic light was never greater than at present. The number of the journals published, instead of making them superior, through the stimulus of competition, renders them weaker, through the want of food. The subscription list being small, the outlay upon the journal must be proportionate. Let us hope, then, for a consolidation of American journals, and also for the abandonment of the Transaction publication, and the adoption, by State Societies, of general subscription to journals in behalf of members."

Charges to Clergymen.—The *American Medical Weekly* speaks in favor of no charge for professional services to clergymen. On principle we believe the doctrine to be correct, but there are many exceptions to the rule, which may occur to every poor practitioner who may consume valuable time in attendance upon a wealthy minister.

Charles O'Reilly, Esq., M.D., on his retirement from the office of Resident Physician of the City Hospital, Hamilton, Ont., was presented with an elegant service of plate. It is unnecessary to say that this is a purely English custom.

Medical Theses.—The *Louisville Medical News* states that the Medical Department of the University of Louisville have decided to abolish the requirement of theses from candidates for graduation.

Swallowing Artificial Teeth.—Two cases of this accident have been recently reported in the English journals.

Floating Kidneys.—Dr. J. Wickham Tegg, of London, wants information concerning cases of floating kidneys.

The Alumni Association of the College of Physicians and Surgeons held their eighteenth annual meeting on the evening of February 23, in the College Hall, corner of Fourth avenue and Twenty-third street. The retiring President, Dr. Alfred S. Purdy, was in the chair, and opened the proceedings with the delivery of his address. He lucidly and tersely explained the circumstances attending the collapse of the effort to unite the college with Columbia College. The proposal, when first made by President Barnard, had found great favor in the eyes of the counsellors and trustees of the medical institution, as they had been for years endeavoring to raise a fund of $100,000 for the endowment of a chair of pathological anatomy, and expected great pecuniary assistance as the result of such a union. But the endeavor had failed, and the Alumni were now compelled to trust to their own exertions. It was never contemplated that they should raise this large sum by their own unaided efforts, but it had been justly considered wise to attempt to raise as much as they could, say about fifteen thousand dollars, and then to make a public appeal. About five thousand dollars had been subscribed, and the McClellan legacy would give them about fifteen thousand dollars more, so that they were now in a condition to renew the efforts which had been abandoned when it seemed probable that all which they desired to accomplish would be done for them by Columbia College. At the conclusion of the President's speech the usual routine of business was entered into, and all the reports were read. Then came the work of renewing the organization by the appointment of fresh officers, and this resulted in the following officials being chosen: President, W. H. Draper, New York; Vice-President, Alexander Dougherty, Newark, N. J.; Secretary, George Bayles, New York; Assistant Secretary, C. S. Bull, New York. There was no balloting for the office of Treasurer, as the appointment is conferred by the Trustees. After the nominations had been adopted, the meeting adjourned to the 29th inst., when the Alumni dinner took place.

Small-Pox Hospitals in Montreal.—We learn from the *Canada Medical and Surgical Journal* that two small-pox hospitals have been established in that city, one for the French (Catholic) and the other for the English (Protestant) people. Dr. La Rocque is physician to both these institutions, much against the wishes of the British Canadians, who prefer Dr. Dugdale, the health officer. The latter gentleman declines to serve, and thus the matter stands.

Nulliparous Uterus.—The diagnosis of nulliparous uterus is still under discussion, and the Obstetrical Society of London have appointed a committee to investigate and report upon the whole subject to the Society.

French Senate.—Four medical men have been elected members of the newly constituted French Senate.

Toothache.—Dr. J. Sawyer (*Practitioner*) cures this troublesome affection with tincture of gelseminum in fifteen-minim doses, every six hours.

Nursing.—A Metropolitan and National Nursing Association for providing trained nurses for the sick poor has been inaugurated in London. Five ladies are already working in connection with the Association, and go from house to house dispensing their Good Samaritan offices. Being under "distinguished patronage," a British contemporary thinks that the Association will be a success.

An Artificial Ice Rink has been constructed in Chelsea, England, by Dr. John Gamgee, the distinguished veterinarian. The ice is produced by the rapid evaporation of ether. This latter is accomplished by an air-pump, worked by a powerful engine. By an appropriate apparatus the ether is afterwards condensed, and can be used over and over again in the same way. With the exception of the steam-engine, the whole apparatus is automatic.

The London Medical Examiner.—We understand that the programme determined on by the proprietor of the *London Medical Examiner* was too independent and radical for Dr. Milner Fothergill, who had been engaged to act as editor, and that since the second week of the appearance of the *Examiner*, Mr. Oakley Coles, the author of "Deformities of the Mouth," and the editor of the *Monthly Review of Dental Surgery*, has become both proprietor and editor.

Treatment of the Insane in America.—Dr. John Charles Bucknill, the well-known British alienist, writes a letter to *The Lancet* (Feb. 2), defending the treatment of the insane in America, in answer to a recent editorial on that subject in that journal.

Diseased Pork.—A pork butcher of Bradford (Eng.) was recently committed to prison for digging up the carcasses of pigs which had died of typhoid fever, and exposing them for sale.

The Washington University School of Medicine, Baltimore, held its ninth annual commencement at Ford's Theatre, Feb. 24, 1876. The degree of doctor of medicine was conferred upon thirty-two graduates. Dr. W. C. Kloman, Professor of Anatomy, delivered the address. The exercises were enlivened with appropriate music.

New York Eye and Ear Infirmary.—The fifty-fifth annual report, for the year 1875, has just been published. During the period mentioned nine thousand four hundred and fifty-seven patients have been treated in the institution, classified as follows: Diseases of the eye, 6,574; of the ear, 2,315; of the nose and throat, 568. The average daily attendance was 120; of these three-fourths of the cases were for eye diseases. A statistical report of forty cataract operations, performed by the surgical staff, Drs. Noyes, Althof, Eno, Derby, Cutler, Bull, and Callan, has been compiled by Dr. W. Oliver Moore, Resident Surgeon, and is a very instructive and suggestive document.

College of Physicians and Surgeons.—The commencement of this institution took place March 1, at Steinway Hall. A full report of the same could not be prepared in time for the present issue.

DIPHTHERIA.

CONDENSED FROM LECTURES DELIVERED IN JEFFERSON MEDICAL COLLEGE, ON MAY 13TH, 17TH, 20TH, AND 24TH, 1875.

By J. SOLIS COHEN, M.D.,

LECTURER ON LARYNGOSCOPY AND DISEASES OF THE THROAT AND CHEST.

TREATMENT.

IV.]

Topical measures can only be effectual when they can be thoroughly applied to the entire exudative product; and their use, therefore, is chiefly limited to manifestations that are accessible to vision. It is generally deemed inexpedient to resort to forcible removal of the membranes, although it is considered allowable when they are partially detached at their edges and but slightly adherent. Some practitioners, however, not wishing to limit the action of the caustic or astringent to the membranes, and doubtful of its action through them upon the mucous membrane beneath, remove the patches forcibly, and then cauterize the bleeding surfaces. The difficulty of effectual topical applications is often very great, and frequently insurmountable, especially when the deposit occupies the upper pharyngeal walls, the internal nasal outlets, the posterior surface of the palate, etc., localities requiring the artificial aid of mirrors to inspect them. Besides this there is great danger of injuring healthy tissues, and thus exciting inflammation, with perhaps effusion beneath the mucous membrane. In addition to this, in certain cases the operation causes a good deal of pain, as well as intense physical and mental suffering, and often interferes in this way with the adequate introduction of nourishment and stimulus, particularly in nervous subjects. It is questionable, therefore, whether it is justifiable to persist in making the applications by force in cases where the resistance is great, and where the outskirts of the visible deposit are out of reach.

If there are but a few circumscribed patches steadily extending in circumference, and fully within reach of instruments, there can be no valid objection to a single thorough local application, in the hope of arresting their progress by continuity. Should this fail, it is hardly likely that anything is to be gained by its repetition. In employing this method we need not forget that the first deposit is likely to be replaced by others; and we are entitled to remember, on the other hand, that this is by no means universally the case, and that therefore there is a possibility of getting rid at once of the local source of danger by a thorough topical application. Of all the local agents that I have employed, and seen employed by others, the tincture of the chloride of iron has been by far the most efficacious. It is believed that aqueous solutions of iron are not as useful as the tincture; and this leads to the inquiry whether its local action may be in any measure due to the alcohol; bacteria are said to be inevitably killed by immersion in absolute alcohol;* and it may be worth while to determine whether the organisms present in the diphtheritic exudation may be destroyed by its local application. Tincture of the chloride of iron, first recommended by Dr. Heslop, of Birmingham,† and by Gigot and Jodin,‡ is at present the favorite topical remedy with most practitioners.

Jodin‡ believes that it penetrates the vegetation completely, limits its action on the surface, and may be absorbed without danger; that it modifies the hemorrhagic condition which constantly surrounds the points of exudation, and provokes a desire to expectorate which facilitates the expulsion of the morbid products. He calls attention to the necessity of exerting a certain amount of pressure in its application, as a liquid simply coursing over the parts can have but an uncertain action; and to the necessity of reaching the entire exudation, as a point spared may be the source of a new deposit. He recommends gargling after the application, and repeating both processes until all is removed. For the nares syringing does instead of gargling. The proper amount of pressure cannot be exerted in the larynx, nor the circumspection exercised to touch every part. Here Jodin recommends tracheotomy and the application of the iron up and down through the artificial opening.

There is but little doubt that this remedy is employed with more general confidence in its efficacy than any other local agent.

The sulphate of iron (Monsel's salt) in powder has been found the most efficacious remedy by some practitioners.§

Hydrochloric acid, extensively employed at one time by Bretonneau, Trousseau, and others, is rarely used by the active practitioners of the present day. The same remark applies to the local use of nitrate of silver, and likewise of calomel, once highly extolled by Trousseau as a powerful modifier of the diphtheritic inflammation.

Hydrochloric acid was employed locally by Bretonneau before he recognized the nature of the disease, and still deemed the diphtheritic aspect of parts denotive of sphacelus.‖ He applied the strong acid at intervals of twenty-four to thirty hours, and believed that it arrested the progress of the specific inflammation by substituting another. The fumes of hydrochloric acid were first employed in the disease in Bretonneau's time, but their use has been abandoned.

Trousseau, likewise, also employed the fuming hydrochloric acid, applied on charpie, repeated twice a day, expecting such modification of the parts after two or three days' use as to justify the application of less active agents. He also employed the concentrated solution of chloride of iron, but abandoned it again for the muriatic acid.

Nitrate of silver is a local remedy that has been extensively employed, and was first recommended by Dr. Mackenzie, of Glasgow¶ as a substitute for the sulphate of copper. Its use has been highly recommended by Bretonneau, Trousseau, and many others. Jenner states** that the single efficient application of a solution of twenty grains to the drachm of water, frequently stays the spread of the exudative inflammation, and he has seen the same result from the solid stick carefully applied around the patch; though he believes that on the whole hydrochloric acid and water in equal parts more frequently attain that object. He reprobates, however, the repeated application of these

** Op. cit., p. 69.

trong local remedies at short intervals. The solid stick, in a holder so guarded that only the cauterizing point is exposed, or strong solutions of the crystals, are alike used for this purpose. Of late years this agent has lost much of its repute in these cases.

Powdered alum was used by insufflation as long back as in the practice of Aretæus,* and successful results in the early stage of the pharyngeal exudation have been reported by Bretonneau, Trousseau, Pommier, and many others. Fifteen grains, mixed with sugar, are propelled on the parts by an insufflator, or blown upon them through a quill or other tube, every three or four hours. Daviot† speaks highly of it in the first stage as generally preventing the formation of membranes. I do not think that it is much used at present.

The local application of powdered sulphur has been highly lauded, especially by Spanish authorities, for its destructive action upon low organisms. There seems to me to be ample reason to acknowledge its efficiency in certain epidemics that have been reported, or, at least, its equality with other topical agents. In other epidemics, again, it is said to have been useless.

Where topical applications by the brush and probang are injudicious or impracticable, local medications by the gargle, syringe, or spray douche are often resorted to. Here solutions of alum, borax, chlorate of potassium, lactic acid, carbolic acid, sulphurous acid, lime, bromine, glycerine, and the like are employed. The stronger caustic and acid solutions are not suitable for this method of employment. Simple water, hot, tepid, or cold, as best suits the patient, impregnated with Cologne water or toilet vinegar, is a grateful application in the form of douche or spray, and often as apparently efficacious as solutions more medicinal. When the exudation occupies the larynx and trachea, topical remedies are most suitably administered by inhalations. Direct cauterizations of the larynx and trachea are still occasionally practised, but the method has been almost universally abandoned as hazardous and ineffectual. Insufflations of alum, calomel, etc., are rarely employed at the present day either. That the local application to the larynx and trachea of nitrate of silver, so highly extolled by Bretonneau, Green, Gibb, and others, has been of great use in some instances, there is no reason to doubt. But it may be doubted whether any special beneficent action is to be attributed to the nitrate of silver, for many indifferent substances employed in the same manner have likewise proved successful in individual cases. It is likely that most of the benefit has been due to the mechanical detachment of the membrane removed, or merely loosened by the contact of the sponge in the execution of the operation. A sponge saturated with water, or with a weak solution of carbolic acid, or the like, would then be equally efficient, and be much less apt to produce intense spasm of the glottis. By placing the index finger of one hand upon the laryngeal face of the epiglottis, it is not very difficult to carry a sponge probang along the guide into the larynx, and by suitable movements to reach most of its interior surface, or that of the trachea, and if it come in contact with membranes they will be removed in part adherent to the sponge, and will be in part detached and expelled subsequently in the efforts of cough.

In cases where tracheotomy is out of the question, or where it will not be consented to, it may be justifiable in the face of impending suffocation from accumulated products to attempt their mechanical removal in the manner indicated, the operation being completed in as few seconds as possible. There is a moderate risk of impacting membranes in the trachea or in the primitive bronchi, a result which would accelerate the very condition for the alleviation of which the operation is attempted; but such instances would ordinarily be very infrequent. On the other hand, removal of obstructing membranes will facilitate respiration for some time, and may save life if there be no reproduction of them. The responsibility of performing the operation is great enough in any instance; and in case of impaction, immediate tracheotomy would be necessary.

The agents administered by inhalation are usually such as have a solvent action upon the morbid product or keep it diffluent so as to favor its expulsion by cough. Various alkalies have a certain solvent action upon the membrane. Lime-water is the most efficient and promptest, and is at present the most resorted to. Iodine, chlorine, bromine, creasote, carbolic acid, salicylic acid, sulphurous acid, and lactic acid are used for the same purpose. With sulphurous acid I have had some successful results. These agents are usually admininistered in the form of sprays.

Bromine vapor has been highly recommended by various observers. Ozanam throws a large pinch of table salt or of bromide of potassium upon boiling water, and adds gradually a teaspoonful of an aqueous solution of bromine, a drop to the ounce. The vapor is inhaled slowly and deeply through a funnel of glass or paper. Leuthlen saturates a sponge in a solution of two parts each of bromine and bromide of potassium in one hundred parts of distilled water, and holds it before the patient's nose and mouth, much in the same way as administering an anæsthetic.

The vapor of ammonia has been recommended to excite vomiting and expectoration.

Tracheotomy.—When there is such evidence of false membrane in the larynx and trachea as to threaten suffocation or asphyxia, and emetics and inhalations fail to effect its expulsion, the operation of tracheotomy is indicated to enable removal of the membrane in the first place, and respiration through an artificial opening, below the point of obstruction, in the second. If the membrane should occlude the bronchi to any extent, there is little to hope from the operation; but this condition is very difficult to determine, on account of the transmission of morbid sounds from the upper passages. The most reliable indication is continuous and increasing dyspnœa with gradual asphyxia, but unaccompanied by incurvation of the tissues above the sternum, or to any considerable extent at the base of the thorax, or in the intercostal spaces. If the tissues named are drawn in to any great extent with each inspirating effort the indication is that the impediment is chiefly in the larynx or trachea, and much more is to be expected from the operation. Great stridor in inspiration indicates obstruction at the glottis. It is not expedient to go fully into a consideration of all the points involved in the question of tracheotomy, as that is a subject that requires a careful study of itself. In a recently published essay,* to which I may without undue pretention refer such of you as are interested in the subject, I have carefully gone over the subject in all its important bearings, and presented the *pros* and *cons* as impartially as I am able to do. It will suffice to state that the operation has been successful in many cases apparently hopeless, and promising but

* Bretonneau, op. cit., p. 42.
† Memoirs, etc., Sydenham Soc., p. 371.

* Croup in its Relations to Tracheotomy, Philadelphia, 1874.

little success. On the other hand, it often fails even in promising cases. Much depends on the selection of cases, the proper performance of the operation, and on the after-treatment. There is no insuperable contra-indication to the operation, unless it be evidence of the deposit of fibrin in the cavities of the heart. Anæsthesia is admissible, if sensation is intact, but must be employed with great caution. The operation must be deliberately performed unless the emergency is such that the patient is sure to suffocate during the dissection. As a rule, hemorrhage should be restrained before the trachea is incised. The false membranes present in the larynx and trachea should be removed by extraction and suction (with syringe or with pipette), before any tube is introduced. Finally, the most assiduous attention must be paid to the after-treatment, as regards disease, wound, and tube. The tube should be dispensed with if practicable, and should be removed as soon as there is no further indication for its use. Above all must it be kept in mind that the operation merely offers a possibility of recovery by affording a means of efficient respiration during the continuance of the disease. It will help the patient to live through the evolution and decline of the disease, but it cannot cure it. It is a chance for life which should not be denied the patient, if the conditions are such that it can be properly attended to afterwards; and the sooner the operation is performed after it is indicated, the better the hope of success. The operation is rarely successful in adults, chiefly because the size of the larynx is such that the mechanical impediment to respiration is not sufficient to call for an artificial opening below it, until after the exudation has invaded the bronchi. I know of but three or four records of success after tracheotomy in the adult, while the records of success in children may be counted in hundreds, some of them in subjects much less than two years of age, although success is very rare at this early period of life. The main indications, after the operation, are to keep up nourishment to sustain the patient, and to encourage or to provoke cough, to keep the air-passages clear. All treatment should be subservient to these ends, so essential for a favorable termination to the case.

The manner in which I have become accustomed to treat diphtheria, modified of course according to the exigencies and individualities of the case, may be stated as follows: The patient is placed in the most convenient room of the house, encumbered with as little furniture as practicable, care being taken to provide for due ventilation and an equable temperature of 75 F. Great attention is given to nourishment, and to systematic alcoholic stimulation, when the strength is becoming exhausted. The nostrils, when clogged, are assiduously cleaned by douche or syringe. Tincture of the chloride of iron is given in full and frequent doses, and applied locally to any circumscribed patches that can be reached in their entire extent. A continuous evolution of steam is kept up in the apartment so as to moisten the air; the throat and nostrils are kept as clean as possible by douches of a weak solution of carbolic acid (two grains to the ounce), and the same is occasionally administered by inhalation in spray. As soon as there is any evidence of morbid product in the larynx, or parts below it, inhalations of the fumes from lime in process of slacking * are administered for ten or fifteen minutes at a time, and repeated every second hour, hour, or half-hour, according to the freedom of respiration and the moisture of the bronchial râles. I give the vapor from slacking lime the preference over inhalations of the spray of lime-water, though I have seen good effects from the latter, and sometimes alternate the two methods. If the lime does not appear to suit the case, or if its good effects are not continuous, inhalations of the warm spray of bromine, a grain to the ounce of water, with a grain of the bromide of potassium, are substituted. Should these likewise prove inefficacious I use the sulphurous acid spray. If the laryngeal symptoms increase, and asphyxia is to be dreaded, I advise tracheotomy as soon as there is marked inspiratory incurvation of the intercostal, substernal, and suprasternal tissues, without waiting for the period of cyanosis, provided that no respite is procured by the inhalations, or by the action of emetics.

I am inclined to regard saturation of the atmosphere with steam † as one of the most valuable elements of the treatment of diphtheria in the presence of exudation in the air-passage; the object being to supply to the exudation an abundance of water to replace that which is lost by evaporation or coagulation in its transformation into membrane, and thus favor its detachment and expectoration. With this view I often keep up a continuous evolution of steam so great as to loosen the wall-paper in papered apartments.

Oertel,‡ a recent authority of some notoriety, places his main reliance in this agent in the treatment of diphtheria in the stage under consideration, with the view of promoting abundant suppuration beneath the adventitious membrane to loosen it, and preventing the propagation of the cryptogamic growth, which he states cannot penetrate into the tissues through the layers of pus.

There are a variety of expedients for obtaining a sufficient evolution of steam. If there is a stove in the room, a vessel of water containing small articles, such as handkerchiefs and napkins, may be kept boiling. If this be insufficient, wet cloths may be hung up about the room and be changed from time to time. A wash boiler may be brought into the room, already filled with boiling water, and an attendant stand by it lifting out articles of clothing on a stick, and then immersing them and lifting them again, keeping it up all the time. A second vessel should be ready to replace the first one as soon as its water fails to furnish sufficient steam. Buckets of water may be brought to the bedside, and hot bricks or bits of heated iron dropped into it. Water may be poured over a hot shovel now and then to get up a sudden copious evolution of steam for the moment, and so on. A tin kettle may be altered so that a long wide spout is let into its side high up, to direct the steam towards the mouth of the patient, and can be fed by an alcohol lamp or one of the cheap gas stoves in common use in cities. If a funnel-shaped tube is soldered into the cover so as to dip down into the water, the supply of steam will be more copious. This croup-kettle is inexpensive, and may replace the more perfect instrument. The air of the apartment should be kept well ventilated by an open window in an adjoining room or staircase, a screen formed by a sheet hung over a line being placed in front of the door of communication, or around the bed to screen the patient from draught. If the room is large, the bed may be brought close to the stove, and sheets may be hung round it so as to retain the steam in its vicinity. The temperature of the apartment may be maintained at 80°, 85° or even 90° F. This steaming is kept up

† Ziemssen's Cyclopædia, New York, vol. ... p. 475.

night and day as long as there is any occasion for it, the amount of heat and steam being then lessened gradually.

In order to assist in the early destruction of the membranes, and to afford inlets through them for the penetration of the watery vapor, I resort to the vapors of slacking lime as recommended by Dr. Geiger, repeating the process every hour or so, or whenever the character of the respiration indicates impediment due to the presence of membrane or its reproduction. Hot water is poured upon small pieces of unslacked lime in any convenient vessel. A large piece of stiff wrapping paper, folded into a funnel-shaped cone, or a stiff paper bag with one corner cut off, and inverted over the vessel serves to direct the vapor towards the mouth of the patient. The patient must not be brought too close to the hot vapor, and his eyes may be protected by a cloth or the hand of the attendant. The ebullition of the lime in slacking forces numerous minute particles up in the steam that rises from the vessel, and are taken with it into the air-passages. It may be that the lime does not act chemically on the membranes, and merely wedges them up mechanically here and there, permitting better access of the aqueous vapor; but that it acts beneficially in forcing the expulsion of shreds of membrane, casts, and the like, there is no doubt.

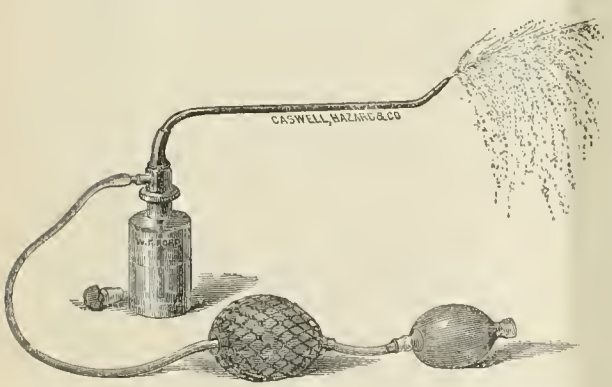
This treatment is likely to induce a catarrhal pneumonia, but if it saves the patient from the immediate dangers of suffocation, that is a secondary matter to be attended to subsequently. I have seen numbers of children saved by this treatment, who, to the best of my judgment, would have perished without it; some of them being cases in which it was believed that tracheotomy held out no chance of a successful termination.

THE SPRAY TREATMENT FOR INFLAMMATIONS OF GENITO-URINARY TRACT.

By E. BRADLEY, M.D.,

NEW YORK.

In a paper which I read before the New York Medical Journal Association, a year ago, I called the attention of the profession to the use of "the spray"



in the treatment of inflammations of the bladder, vagina, and womb, and presented an instrument which I devised, and had been using for some time in the treatment of those diseases.

Since that time I have used the instrument very extensively, and have found it of so much service that I again take the liberty of bringing it before the profession, in the hopes that they will be induced to give it a trial, feeling confident that *all* who use it will find this means of medication infinitely superior to the uterine probe (armed with cotton) the use of injections, glass tubes, and *all other means of intra-uterine application*. By its use we are enabled to reach every part of the uterine cavity, and bring our medicated substances to bear directly on the mucous membrane.

My plan has been to first spray the uterine cavity with tepid water, after which I use solutions of iron (sesquichloride), iodine, carbolic and salicylic acids, of different strengths, as the cases may require, adding to the solutions a little morphine where an *unusual* amount of tenderness exists.

During the past two years I have had the satisfaction of seeing many obstinate cases of cystitis and endometritis yield to the use of the medicated spray, after resisting many other modes of treatment, and I have never yet experienced, in using it, any inconvenience from uterine spasm or excessive pain.

The instrument is made of vulcanized rubber (capable of resisting the chemical action of any substance which one would be likely to use in the cavities of the bladder and womb). It is made like the ordinary spray instrument, with the addition of a *long arm*, properly curved, to enter the cervical canal, and to pass into the bladder, and if displacements of the womb are met with, the curve can be changed to the proper angle to suit the case by heating.

The accompanying wood-cut gives a good idea of the instrument I am now using.

Many cases might be given in detail illustrating the happy effects of this mode of treatment, but I will leave that for some future article, in the hopes that this will suffice to induce my professional brethren and all progressive gynecologists to give it a trial.

Before closing this article, I desire to add that I have found it necessary in some cases of cystitis (where the bladder was very sensitive, and its walls much thickened from inflammation), to use the spray very sparingly, and to meet such cases I am having an instrument constructed (similar to the one described in the accompanying wood-cut) with the addition of a channel or groove, so as to admit of the exit of all the air from the bladder, thereby relieving the tension of its walls

1 W. 24TH ST., NEW YORK.

BRITISH ARMY MEDICAL DEPARTMENT.—One of the proposed measures of reform and amelioration of the Army Medical Department of Great Britain is likely to take the form of what is called short service. Medical students, as soon as they have obtained the necessary licenses to practise medicine and surgery, will be invited to compete for positions in the army on the understanding that they will only be required to serve in it for a limited period, say ten years, at the end of which time they will be free, or rather be required to retire. A certain bonus, the amount of which is not settled, will be given them on retirement. This arrangement, while it may help the government in filling vacancies, and will do away with the retirement on pensions, will very seriously weaken the service by depriving it of the skill and experience of the old army medical officers in the administrative departments. It is probable, however, that some modification in the general plan will be made to remedy this difficulty.

Original Lecture.

GALVANISM IN SKIN DISEASES, NÆVUS, FAVUS, PHLEGMONOUS SCROFULIDE, PEMPHIGUS, MOLLUSCUM CONTAGIOSUM, ETC.

BEING A CLINICAL LECTURE DELIVERED FEB. 7, 1876,

BY PROF. HENRY G. PIFFARD, M.D.,

UNIVERSITY OF THE CITY OF NEW YORK.

(REPORTED BY DR. GEO. H. FOX.)

GENTLEMEN:—As this is the last opportunity I will have of addressing you before the close of the winter session, I cannot let the occasion pass without asking your attention to a certain physical force which may sometimes render efficient service as a remedial agent in connection with diseases of the skin, as well as those of other parts of the body. I refer to galvanism. This agent may be used in five different ways in the treatment of disease, and with results varying with the manner of application. In two of these the galvanism is employed indirectly, in three directly. In the former it does not enter into or modify the tissues, but induces other phenomena which are then employed remedially. In the latter it does enter the body and directly affects the parts. These applications are:

1. To excite an induced electrical current in a coil of wire surrounding a temporary magnet (*indirect*).
2. To produce *catalysis* (*direct*).
3. To produce *electrolysis* (*direct*).
4. To produce *coagulation* (*direct*).
5. To produce an intense heat in a small piece of platinum or other metal (*indirect*).

The nature and effects of the induced electrical current have already been fully explained by one of your other teachers, and need not detain us at present. The other four applications of galvanism I shall allude to but briefly, and simply to explain them, in order that you may obtain a clear idea of the fundamental principles which underlie the employment of this agent, and the kinds of phenomena which it is capable of producing. Attempt at detail would trench too deeply upon the time at our disposal.

By *catalysis* we mean a modification of nutrition. If the current from a galvanic battery, composed of a number of cells properly joined, be passed through the body by means of moistened sponge-covered rheophones applied to the surface, we may in one instance, by stimulating the nervous system or the circulation, exalt the vitality of parts in which it is depressed; in another instance we may subdue pain; in a third, remove pruritus; in a fourth, hasten the resolution of an inflammation; in a fifth, reduce an infiltration; and in a sixth, cause the partial or total disappearance of a tumor. These are all effected by modifications of the local nutritive processes, whereby absorption is rendered more active, and normal action supplants the pathological. As these changes are effected slowly, it will be impossible for me to give you a demonstration of them.

By *electrolysis*, on the other hand, we mean the direct decomposition and destruction of tissue elements, and of the fluids which surround them. The simplest illustration of the electrolytic effects of the galvanic current is the decomposition of saline solutions. If, for instance, the current be passed through a solution of iodide of potassium, this compound, as well as the water, is split up into its component elements. By looking at the screen (a magic lantern was arranged with a glass cell containing a dilute solution of potass. iod. at its focus; into this were introduced wires connected with the poles of a battery) you will see, the moment the current passes through the fluid, an active change occurring in the solution. At one wire we see a brownish discoloration, at the other the development of numerous bubbles. Oxygen, acids, and similar bodies collect in the neighborhood of the positive pole; hydrogen, alkalies, and basic substances at the negative. In this instance the oxygen, resulting from the decomposition of the water collecting at the positive pole, rapidly oxidizes the metal of which the wire is composed; the free iodine, also collecting at this point, discolors the solution in the neighborhood. At the other pole the potassium is free, but, being readily soluble, is unperceived; while the hydrogen, unable to combine with the wire, escapes in the form of little bubbles. If now, instead of dipping the wires into a saline solution, they are plunged directly into the body, the same phenomena will occur, and the tissues and fluids in their immediate neighborhood will in like manner be split up into their elements or into simpler compounds. As the tissues, however, are very complex in their composition, additional phenomena occur. These are, first, an appreciable elevation of temperature in the wires, which effects a slight cauterizing action upon the parts; and second, at one of the poles a slight tendency to the coagulation of albuminous and fibrinous substances. This latter effect is readily demonstrated. If you again look at the screen (the cell containing the potash solution was replaced by one containing albumen, and the wires adjusted as before) you will see, when the circuit is closed, that bubbles of hydrogen appear at the negative wire, but at the same time the positive wire is becoming surrounded by a dense mass of opaque material, which in this instance is coagulated albumen. From this we see that *electrolysis* is most active at the negative, and *coagulation* at the positive pole. Electrolysis enables us to destroy morbid growths, and coagulation enables us to occlude vessels by the formation of clots. The particular indications for these uses of galvanism we have not at present time to consider.

The last (*indirect*) application of galvanism is what is known as the galvano-cautery. If a strong galvanic current passes readily through the wire which connects its poles, it does so without creating much disturbance; but if its passage is resisted, heat is developed at the point of resistance. Platinum is a resisting body, and if a small piece of it be introduced into the circuit, it soon becomes red and then white hot (this was demonstrated with a small cautery battery). This heated platinum may then be used as a counter-irritant, as a hæmostatic, or for the destruction or removal of morbid growths. The other day you were shown a tumor which I had removed in this manner. I will now show you a photograph of the patient before the operation (the photograph was projected upon the screen about twice the size of life; it displayed an hypertrophied *præputium clitoridis*, which after removal weighed 6½ ounces). We must now leave the subject of galvanism, and give our attention to the patients who are waiting in the ante-room.

CASE I.—The first one (a man aged 45 years) is one whom you will recognize as a former case of Eczema. To-day he desires the removal of a small Nævus just beneath his left eye. This may be effected in a moment by the introduction of a couple of needles con-

nected with the poles of the battery (this operation was then performed). We have now destroyed most of the enlarged vessels, and coagulated a portion of the blood. In a few weeks there will be but a slight trace of the nævus; in a few months it will be impossible, perhaps, to discover its former site. This application of the galvanic current is one of the most effectual and convenient methods of treatment in this affection. I cannot detain you with further remarks concerning nævus, as we have to-day an unusual collection of rare and interesting cases, some of which I may never again have an opportunity of showing you.

Case II.—A boy, 18 years of age. Four weeks ago I showed you a case of Favus of long standing, and in connection with it an ordinary house mouse affected with the same disease, and which had been given me by my friend Prof. Keyes. The present patient is another case of Favus, of two years' standing. As the nature and treatment of this disease was fully considered the other day, I shall not repeat what was then said, but will simply present the case to you for inspection, and at the same time pass around a cage containing a white mouse, which I placed in a cage with the other one a month ago, and which has contracted the disease from it, and exhibits some favus crusts within the right ear. Remember that this disease is not only contagious from one human being to another, but it may also be conveyed from mice to cats, and from cats to children who play with them. It is important, therefore, that you should be able to recognize the disease in the lower animals as well as in man.

Case III.—A girl, aged 23 years. Last week we had a case of Erythematous Scrofulide (*lupus erythematosus*), but this one is a phlegmonous scrofulide, and presents itself as a small, bluish red tumor upon the left side of the nose. The tumor is oval, and about half an inch in length and a quarter in breadth, and looks like a small abscess ready for opening. It is, in reality, a dermic phlegmon, but, instead of being soft and fluctuating, is firm and hard. The course of these lesions is chronic, and their progress exceedingly slow. It may be weeks or months before they soften and suppurate. When this occurs, a tedious ulcer, discharging a thin, ill-conditioned pus is the result, with finally an indelible scar. These lesions are, without question, scrofulous manifestations, and demand a constitutional treatment adapted to this condition. The indications for local treatment are, in the early stages, to procure resolution, if possible. This may sometimes be accomplished with mercurial and iodic applications. If softening, however, has occurred, the pus should be aspirated with a hypodermic syringe, and a drop or two of dilute iodine afterwards injected.

Case IV.—A man, aged 40 years, with Pemphigus. This is a disease always characterized by an eruption of bullæ, but under the same name have been included a large number of cases, varying greatly in respect to nature, course, and cause. For instance, the name has been applied to an affection of young children, in which a bullous eruption occurs and runs an acute course; to a bullous eruption affecting infants who are the victims of hereditary syphilis; and to various anomalous eruptions characterized by the presence of bullæ. I prefer limiting the term Pemphigus to a certain chronic relapsing affection of adults, of which the case before us is a striking example. This case, which had been diagnosed as syphilis, was undergoing the usual specific treatment, and passing from bad to worse, when he first came under my observation. Under the influence of arsenic, a marked improvement in his condition has become manifest.

Case V.—This man presents a tolerably common and often obstinate affection of the beard known as Sycosis or "barber's itch." It is an illustration of the non-parasitic variety, being due to a simple inflammation of the hair follicles, and hence presents a contrast to the cases of ringworm of the beard which you have seen, and in which the eruption results from the presence of a vegetable parasite, the *tricophyton tonsurans*. The treatment is nearly the same as in the parasitic affection, namely, epilation, followed by the white precipitate ointment.

Case VI. is an infant exhibiting that very common affection eczema of the face. In this case a proper diet, with the administration of syrup of the iodide of iron and cod-liver oil, and topical application of any emollient ointment, will speedily effect a cure.

Case VII.—I have now the pleasure of exhibiting to you an extremely rare and interesting affection of the skin known as Molluscum contagiosum. The boy is a patient of Dr. Fox, to whom we are indebted for this opportunity of studying the affection. Scattered upon the breast and back you notice a number of button-like elevations rising abruptly from the surrounding skin. They are seen to be small, flattened pouches of skin, containing a white, semi-solid, cheesy matter, which may be seen exuding from a central orifice when pressure is made upon the sides of the little tumor. Some of them are slightly umbilicated, like the mature pustules of variola, to which they bear no small resemblance. The nature of this affection is very obscure, and its contagiousness has been the subject of dispute. And now, as I have already trespassed upon your time, I will merely ask you to observe this case very closely, that you may readily recognize it should you ever have the opportunity of seeing a similar one. The treatment consists in squeezing out the contents of the little tubercles, and applying nitrate of silver freely to their interiors.

Progress of Medical Science.

When we May and When we May Not Bleed.—Dr. Henry Moon thinks that the indiscriminate use of blood-letting, years ago, destroyed many thousand lives annually. In some cases, however, with the light of modern science, it is still a remedy of great practical usefulness. In cerebral hemorrhage, if the impulse of the heart be strong and its sounds loud, if the pulse be regular and no signs of œdema of the lungs exist, the patient should be bled without delay. Here a judicious timely bleeding may prevent the extension of the paralysis from the cerebrum to the medulla oblongata. The patient may not be bled, on the contrary, when the heart's impulse is weak, the pulse irregular, and rattling in the trachea has already begun. In acute croupous pneumonia bleeding may be beneficial when the pneumonia has attacked a vigorous and hitherto healthy person, the temperature being higher than 100° Fahr., and the pulse rating at more than 120 beats in a minute. In those, however, who are already debilitated, bleeding increases the danger of exhaustion. Should the fever in pneumonia be moderate, venesection is not indicated, even in healthy and vigorous individuals. The result of a bold venesection in fluxiou of the lung, arising from excessive

cardiac action, is astonishing. As soon as the volume of the blood has become lessened, the pressure diminishes in the arteries, the patients often breathing more freely during the operation. The bloody foam which they were expectorating vanishes, and life may be rescued from the greatest danger by aid of the physician. Bleeding should never be used in cases of long standing disease of the heart, except under the most pressing circumstances. In endocarditis bleeding is decidedly injurious, yet at times a condition exists, such as overcharge of the pulmonary circulation, threatening œdema of the lungs, when prompt relief by diminution of the blood is demanded.—*British Medical Journal*, January 15, 1876.

Puerperal Fever.—Dr. William O. Priestly, in an address before the London Obstetrical Society, gives especial prominence to the question whether puerperal fever is a specific disease. He thinks that clinical investigation and pathological research have both in recent times been teaching that what has been called puerperal fever or fevers are but forms of blood-poisoning or septicæmia, similar to those observed in other than puerperal patients, having, it may be, a diversity of origin, and intensified and modified, perhaps, by the peculiarities of the puerperal state; but still they are essentially the same, and do not constitute a pathological genus apart. Dr. Barnes says that the origin of the poison, whatever may be its nature, or chemical composition, has two sources. In the one case the virus is found in the patient's own body, as the result of initial morbid changes in some special part, which effects eventually the rest of the system: in the other case the virus is imported into the body by contamination from without. To the one class of cases he applies the term "autogenetic," to the other, "heterogenetic."

A warm discussion has taken place as to whether puerperal fever is epidemic or endemic. Dr. Mathews Duncan doubts the evidence of its epidemic character altogether. As to the contagious quality of puerperal fever, the direct proofs have accumulated to such an extent that to disregard them would be a plain dereliction of duty on the part of a medical practitioner. —*British Medical Journal*, Jan. 8, 1876.

Rapid Dilatation of the Female Urethra.—Dr. George Jewett relates a case of a girl, 15 years old, who had introduced the handle of a crochet-needle, through the urethra, into the bladder. The foreign body was easily detected with the sound, but it was firmly fixed at both extremities, and any effort to move it caused great pain. Digital exploration of the bladder was then decided upon. Ether was administered, and a No. 16 male sound was introduced, the index finger, well lubricated, following its introduction. A rotary motion, with moderate force, brought the finger to the base of the second phalanx, where further dilatation without rupture seemed impossible. The bladder was empty, and the foreign body easily reached. The lower extremity was two inches to the right of the meatus, and while endeavoring to lift it out of the base of the bladder, a sudden rupture of the meatus occurred. After some difficulty the finger-nail was introduced under the point of the needle-handle, and the finger being gently withdrawn, the vesical contraction forced the intruding body far out of the meatus. There was moderate hæmorrhage, which ceased spontaneously. The patient was put in bed; opiates were given, and fomentations ordered to the pubic region. In two weeks the recovery was complete. Allusion is made to the fact that in such cases Simon advises two incisions to be made in the meatus; one superiorly, of one fourth a centimetre, the other inferiorly, of one-half a centimetre. —*Boston Medical and Surgical Journal*, January 27, 1876.

Amyloid Degeneration of the Muscular Structure of the Heart.—Leonhardi's violet ink, as a test of great delicacy for the amyloid degeneration of tissues, has fully maintained its reputation; and now Prof. Heschl, of Vienna, reports that by its use his assistant, Dr. Breus, has detected this form of degeneration in the vessels and in tissue between the primitive bundles of heart muscle. Prof. H. had never before succeeded in verifying this state of things, although suspecting it to exist. The arteries and capillaries, and also the connective tissue surrounding them, gave the characteristic reaction; and in regard to the muscular elements it was found that the degeneration was manifested in an envelope of homogeneous non-nucleated tissue, which surrounded with a more or less complete envelope one or several of the primitive bundles, while they themselves were unaffected. In this connection, attention is also called to the fact that the heart muscle has no sarcolemma, and thus the amyloid degeneration described above must have involved an enveloping tissue of new formation, and presumably exudative in its origin. Heschl therefore regards this as confirming his views of the origin of the like degeneration in the liver, as opposed to the views of Rindfleisch, who states that it is the liver cells which are the chief seat of the waxy change.—*Wien. med. Woch.*, 2, 1876; *Allg. med. Central-Ztg.*, 5, 1876.

The Fixation of Cochineal Carmine in Living Anatomical Elements.—At the meeting of the *Société de Biologie* on December 11th, M. Pouchet reported the results of the following experiments: A tablet of fine carmine was dissolved in water to the consistence of paste, and injected into the lymphatic sacs of eight frogs, a mass equal to about two cubic lines being injected into each animal. In a day or two the leucocytes of the blood were loaded with grains of carmine, and soon the tendons and fibrous tissues generally became colored by a true imbibition, not by a granular deposit of the carmine. The fibres and cells were both tinged. When acetic acid was added to a fragment of tendon or aponeurosis under the microscope, the fibres swelled and the coloration consequently became less marked, while the cells preserved their color. The nuclei were not more deeply colored than the bodies of the cells. The subcutaneous fascia, the sclerotic, and the non-calcified portion of the dental socket were colored a bright red. The epithelium and the epidermis, the crystalline lens and its capsules, the cornea, the basement substance of the bones and of the cartilages and their cells, and the muscular substance presented no traces of coloration. Even the protoplasm of the leucocytes was not colored, although it enclosed grains of carmine. The nervous elements were entirely exempt from coloration. A notable peculiarity was a light coloration of the external segment of the rods of the retina, which disappeared rapidly on the addition of water or alcohol. This coloration of the rods is remarkable, because after death this layer colors very slowly, while the granular layers do so very rapidly.

In order to explain this fixation of the carmine we must first admit that a small quantity of it was dissolved by the alkaline serum, whence it passed, by reason of special chemical conditions, into certain determined tissues and anatomical elements. It is possible, however, that had the experiments been continu-

used longer, a larger number of tissues would have been affected. The coloration did not seem to be so ephemeral as that obtained with indigo-carmine. The carmine granules disappeared rapidly from the lymph-sacs, having been taken up by the leucocytes, which appeared to be increased in number. During the first few days, no free granules were found in the blood. The red globules contained no granules. The leucocytes charged with carmine accumulated rapidly in the capillary networks of the liver, kidneys, spleen, lungs, and medulla of the bones, giving them a rose color, which was not due to imbibition, but was comparable to that produced by a successful fine injection. If all the capillaries of the body were filled with these leucocytes, of course hæmatosis could not take place, and the animal would die. These observations formally contradict the generally admitted proposition that living bodies cannot take up carmine.—*Gazette Medical de Paris*, Dec. 25, 1875.

Diffuse Phlegmonous Periostitis.—In discussing a paper of M. Duplay in the *Société de Chirurgie*, M. Giraldès endeavored to point out the characteristics of this affection, which he claims is very often mistaken for periostitis, osteitis, or osteoperiostitis. He held it to be characterized by the gravity of the general symptoms, the typhoid aspect of the patient, and the intensity of the fever; locally the suppuration is deep and abundant, and detaches the periosteum to a large extent from the bone. Early resection was said to shorten the duration of the suppuration, and secure the preservation of a healthy periosteum, which can reproduce a bone but little deformed, and without invagination of a sequestrum.

M. Trélat thought it was difficult to distinguish between the different forms of osteitis and periostitis, and that early intervention, though excellent in grave cases, might be dangerous under other circumstances. He held that necrosis is due to suppuration in the Haversian canals. M. Verneuil protested against the idea that separation of the periosteum necessarily causes necrosis of the whole bone, and mentioned several cases where extensive denudation of the shafts of the long bones was followed by the loss of only a few splinters. M. Guyon mentioned the case of a child suffering from diffuse phlegmonous periostitis, who was cured by incisions and drainage.—*Journal de Méd. et de Chir.*, Jan., 1876.

Epilepsy of Thirty-three Years' Standing Cured by Rheumatism.—Mr. Edmund B. Whitcombe gives the history of a female, who came under his observation at the Birmingham Borough Lunatic Asylum in August, 1870. She had been admitted ten years before as an insane patient, the supposed cause being epilepsy. During the first year (1860) she had from ten to twenty fits a month, these chiefly occurring at night. In 1861 she suffered from amenorrhœa, and at frequent intervals, for the following eight years, she had irregular menstrual discharges, at times amounting to menorrhagia. During this period there was a large increase in the number of fits; she became anæmic, and was very feeble mentally. When first seen by Mr. Whitcombe (1870), she was thin, very pale, and complained of frontal headache and palpitation of the heart. Mentally she was depressed, and appeared frightened at trivial matters. Full doses of the tincture of perchloride of iron and a liberal diet were given, under which she improved. In May, 1872, she had an attack of acute rheumatism, which left her in a chronic state of rheumatic arthritis, the wrist and knees being implicated. During the following year (1873) she suffered much, especially from the left knee, which, in the early part of 1874, swelled, became hot, red, and exceedingly painful. Suppuration and partial luxation of the joint quickly followed, and, after consultation, the limb was removed just above the knee. The operation was well borne, and from this time onward she progressed rapidly, and in less than a month was able to sit up; the stump had healed, and her general condition had much improved. In November, 1875, she was in good bodily condition, and free from pain. She was bright, happy, and rational in her conversation, and her memory was improved. There had been no epilepsy, nor any sensation of a coming fit, since June 4, 1872. From the time the patient was admitted (1860) to the time the fits ceased (1872), she had 2,531 attacks of epilepsy, the greatest number in one year being 502. Mr. Whitcombe thinks the most interesting feature in this case is the complete cessation of epileptic fits after an uninterrupted suffering for thirty-three years, and, with that, the return of the mental power. The use of medicines, or any improved bodily condition, cannot be accredited with these satisfactory results. The case presents itself simply as one of metastasis. The epilepsy succumbed to rheumatism, in which, according to Dr. Sieveking, a "genuine blood disease" is not unfrequently followed "by a permanent cure of the epilepsy."—*Journal of Mental Science*, January, 1876.

Specula for Examining the Female Bladder.—At a meeting of the Obstetrical Society of Edinburgh, held July 14, 1875, Mr. Mathews Duncan stated, that he had recently been paying renewed attention to bladder diseases, especially chronic cystitis. He had repeatedly dilated the urethra to a large degree, and found that it relieved the cystic symptoms. Through the urethra so dilated, by Simon's vulcanite tubes, the interior of the urethra and bladder can easily be seen. In order that a thorough visual examination may be made, he now uses common glass specula, three-quarters of an inch in diameter, or larger, with internal mirror surface. They show the inside of the organ, as well as similar, but larger, specula show the vagina and cervix uteri. The whole operation of dilating and examining the bladder, exclusive of the use of chloroform, does not take more than five minutes.—*Edinburgh Medical Journal*, December, 1875.

The Antiseptic Treatment of Empyema.—Dr. Alexander J. Sinclair emphasizes the statement, that the successful treatment of empyema cannot be carried out without permitting the escape of the fluid by means of an opening. Where, by what means, and by what method this opening is to be made, and what treatment is necessary to effect a cure, are the important questions. He thinks it is strange that a fistulous opening is not made at the onset of the disease, and that the patient should be exhausted by previous successive tappings, before nature or the surgeon has established a patent external opening, without which few if any cures can be effected. He then mentions two cases, which were successfully treated, by opening the cavities in the manner recommended by Mr. Lister. The best method for the patient is to make a fistulous opening at once, this method being robbed of its dangers by carefully making the incision, and subsequently dressing the wound antiseptically. Independently of the freedom from danger, the cleanliness and comfort to the patient can only be known to those who have seen the profuse discharge of pus from the ordinary fistulous opening in the pleura, after empyema.—*Edinburgh Medical Journal*, December, 1875.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, March 11, 1876.

SUCCESS IN A CROWDED PROFESSION.

As we have just recruited the army medical with between three and four thousand graduates we have another opportunity for moralizing in a general way on the professional prospects of these new-comers into our ranks. So long as the bugles blow, the drums beat, the bands play, the banners fly, and the commencement addresses are being delivered, there is no end of enthusiasm; and as each young soldier grasps his parchment commission there is that quiet determination to succeed in his future calling, which is simply terrible to contemplate. No doubt a great deal of this is a genuine feeling on the part of the young graduate, and may, with a few, be kept alive long after the music has died away and the tinselled promises of the orators shall have become dimmed by the every-day work of the plodding, struggling, and half-starved practitioner. But even with this few, despite the enthusiasm, anything like brilliant success will, we fear, be the exception rather than the rule. This, it is true, is rather a melancholy background to what would otherwise be a bewitching contemplation for every ambitious youth; but facts are cold, stubborn, and uncompromising, and will have their way.

We know that it is the custom for the professors to hold out brilliant hopes to their classes, and to promise them all sorts of rewards for their labors; but by actual experience, these hopes are seldom if ever realized. The whole trouble lies in the present system of medical education, which, disguise it as we will, is carried on almost solely for the benefit of close corporations, in the shape of medical schools. There is every inducement offered to enter these institutions, large classes are desirable because they pay, and when the end comes the graduate is dismissed with a benediction, to find out too late that their so-called brilliant attainments are really a drug in the market. It is well enough to say that there is always room in the front ranks; but we should like to have it proved that even these are not full to overflowing. We do not mean to be understood as saying that there is not need for improvement in the science of medicine, not room for more brilliant minds, and better scientific work; but we are base enough to view the position from a pecuniary point of view. It is an old saying that a crow can never fly so high that he is not compelled to come down to get something to eat.

It is true every one is made to understand, even by the college professors, that the profession is not one from the practice of which a fortune is to be gained, but it is also confidently if not blindly and wildly asserted, that by hard work a competency is assured and an enviable reputation attained. We believe in the latter condition, but not in the former. It is well known that the larger number of really talented men in our ranks were poor, and so far as statistics would seem to prove, the greater a man's reputation was, the less was his income apt to be. The exceptions to this rule, even in our own day, are more apparent than real, for our most successful men in practice, in a pecuniary sense, are not those most respected for their learning among their peers.

But the commencement orator, allowing for the sake of the argument that the ranks are crowded, still maintains that above the common struggling mass of ordinary intellects there are vacancies of position which every conscientious worker may help to fill, and still there will be room. This is to be understood as that higher realm of thought in which their teachers dwell, and in which there is none of that base rivalry for preferment, and none of that meanness of purpose which characterizes the lower stratum of professional society. While we forgive the innocence of such an assumption, we are discourteous enough to deny the fact. If some of these young men should ever dare, unsupported by some college ring, by social influence, or political patronage, to apply for a hospital appointment or professorship, they may be somewhat astonished at the amount of jostling, elbowing and toe-treading there is in the upper and roomier realms of professional distinction. Talk of the dignity of their profession! What would these aspiring, high-minded young men think of their pet professor button-holing some pot-house politician to obtain a position on a hospital board? What would they think of gentlemen of standing and influence stooping to displace their brethren on such a board, for the sake of filling the vacancies themselves? But as this is all done for the good of the colleges, these freshly graduated men may, in charity, claim that the end justifies the means.

The majority of these young men, however, cannot hope as yet to apply for such a position; but they intend by hard and conscientious work to prepare themselves for it. A goodly number, however, must, during the whole of this time, earn their living. Let

us for a moment watch their progress. Starting with the assumption that good, honest work must always tell, their livelihood seems a secondary consideration. The encouraging words of their teachers echo in their ears so long as they have an overdose of conceit of their own unaided abilities, and then unappreciated merit sinks into the struggling, grumbling, and unsuccessful crowd below. They find that there is no room to spread themselves above, and consequently they must be crowded below. They are not now aware of the fact that there are hundreds of young, aspiring, energetic, studious men, who, despite their acquirements, are unable to gain a decent living. Even the specialties are so crowded that, in order to practise them in some localities, patients are solicited to come for free treatment to infirmaries, dispensaries, and college clinics. This may be a method of gaining a reputation, but hardly one for making a living.

Again, does the young aspirant expect to succeed to his preceptor's business? Does he expect his teacher to aid in the hand-to-hand fight with threatened impecuniosity? From what we know of medical men generally, we are compelled to dispel his hopes. We can expect the realization of the latter when we find any older medical man making more money than he cares to collect, or having a larger field of practice than he cares to control. The instinct of self-preservation grows so strong with age, that usually, if there is any show of help at all towards the younger practitioner, it has a tendency in the end to add to the influence and increase the emoluments of the principal. If this young man chooses to be independent of such help, and has the right sort of pluck, and is willing to wait for a vacancy created by the death of some neighboring practitioner, he will eventually succeed. When the "grinders are few," "the almond tree flourishes," and the grasshopper is getting a little unsteady in his jump, he will generally find that he has enough of business, enough of bread to eat, and will also understand why he cannot afford to throw his hard-earned competence into the lap of some expectant and over-ambitious youngster. In the meantime the latter has plenty of opportunities for knowing that he is an intruder in the neighborhood. He does not appreciate this, when he first hangs out his sign. The mock civility with which he is usually received by his medical brethren so completely disarms him that he is rather encouraged than otherwise. This reception is considered by some to be in accordance with medical etiquette, and the honor and dignity of the young aspirant is considered safe. After a while, however, he discovers that in proportion as he may succeed in a small way in practice, in that proportion his patronizing friends grow cool, and he is more than ever conscious that he is forcing himself into a company in which his presence is not needed. How often we have heard it said: "Another doctor has come among us to help divide up what little patronage we have." This is the bread-and-butter question, which thrusts itself upon every medical community over the land after every graduating season; yet the college professors say, year after year, "Plenty of room in the profession for you, gentlemen. We want you all," and the colleges continue to bid for larger classes and to glorify themselves over their success in obtaining them.

In what we have said we have had reference to competent men—men who have had excellent opportunities for medical education, men who should succeed, but who, in consequence of the crowded state of the profession, cannot hope for the fulfilment of their ambitious desires. It is very pleasant to think that there is always room in the front rank by the occasional dropping out of a great man, but the more crowded the line the less chance is there for those at the foot to feel the motion which the vacancy may occasion.

THE INTERNATIONAL MEDICAL CONGRESS AT PHILADELPHIA.

If we were not otherwise informed, we might infer from the tone of the Philadelphia correspondent of a weekly contemporary, that indecision and unnecessary secrecy had characterized the preliminary arrangements for the International Congress to be held in that city in September next. But this view, as the writer himself almost confesses, is based on the fact that he found it impossible to gratify an over-anxiety to obtain the information he needed for publicity at a time when it was very undesirable that the Centennial Medical Commission, which was responsible for the faithful preparation and execution of the fully matured programme, should publish the, as yet imperfectly digested, plan of the entertainment they were about to offer. No one should be so hypercritical as to blame a generous host for hesitating to exhibit to a prematurely impatient interviewer his half-set tables, which in due season will groan with plenteousness and variety.

The work outlined for a Congress like this is of no simple kind; its details must be considered and reconsidered in every possible shape, and what may be deemed an attractive feature one day may on the next be judiciously substituted or supplemented by something of a still more interesting and magnetic character. It is therefore an unkind stab, inflicted in the house of its own friend, that the Commission should be charged with doing, only to undo at the first favorable opportunity. We learn, indeed, that this has never been done, except where strength and tone were to result from the change. The International Congress at Philadelphia has the advantage of being without a parallel; no previous Congress of a like kind is in any way connected with it. It stands on its own merits, and has no Congressional ancestral line in which it occupies a position by direct descent.

An original programme can therefore be effected by

the untrammelled Commission, and excellent material will be at its command. We have previously alluded to internationality as a desirable characteristic of the Congress; but the Commission must labor under a serious difficulty in this respect, however active they may be in their efforts to secure it, in not being able to know exactly whom and what to expect from abroad as contributors and contributions to the attractions of the sessions. The history of European congresses is very different; there is no great ocean to cross, and no long absence from other duties required to attend any such assemblage, so that many distinguished men may come from far and near to mingle in the deliberations. In such doubt the Commission will be, of necessity, compelled to arrange a schedule of entertainment, in which the main work of the Congress will be done by their fellow-countrymen, while every opening and facility will be afforded for the reception of all foreign material that will be offered them. When the preliminary programme of each day's work shall be issued, as we learn it shortly will be, we shall more fully refer to its salient points.

Reports of Societies.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Stated Meeting, February 28, 1876.

DR. T. ADDIS EMMET, VICE-PRESIDENT, IN THE CHAIR.

ON GLEET, AND ESPECIALLY ON ITS RELATIONS TO STRICTURE OF THE URETHRA.

THE discussion commenced at the last stated meeting, upon a paper read by Dr. H. B. Sands, the President, on the above subject, was continued, and was opened by Dr. F. N. Otis, who is the chief advocate of the views attacked by the President in his paper.

DR. OTIS first alluded to the relations which gleet, stricture, and gonorrhœa sustain to each other, and believes that, inasmuch as all gleet depends upon stricture, and not upon gonorrhœa, the important question to be discussed in this connection has reference to the nature and causes of stricture. Having settled these, the different kinds of gleet will be sufficiently indicated. The summary upon this point, according to Dr. Sands, and referred to by Dr. Otis, is that the causes of gleet are not determined by post-mortem examination; that the examinations made during life do not afford any definite information regarding the causes; and that the effect produced by local measures, or constitutional remedies and management, do not furnish any well-established data upon this point. Dr. Otis conceded the efficiency of remedies, local and constitutional, in the treatment of gleet, but at the same time maintained that the cessation of the discharge does not necessarily indicate a cure, and also that it is very liable to return in consequence of trifling excesses of almost any character. But, says Dr. Otis, why go through all this inquiry as to whether the gleet depends upon a chronic inflammation, or is relieved by constitutional remedies, gleet specifics, injections, bougies, etc., etc., before asking the question with regard to its relation to urethral stricture? Dr. Otis raises the question at once, and regards chronic urethral discharges, as a rule, dependant upon strictures, whether from gonorrhœa or some other inflammatory process. Dr. Otis does not believe, however, that stricture of the urethra is necessarily caused by gonorrhœa. It is most often brought to the notice of the surgeon by that disease, but certain conditions may have been present previously, such as thickening of the mucous membrane, local spots of irritation, etc., which are increased and intensified by the gonorrhœa. The gonorrhœa is not the cause in such cases, but simply aggravates and intensifies previously existing conditions present in the urethra, which have given no special inconvenience until affected by the inflammatory processes of this affection. At this point, Dr. Otis fortified his position by quotations from Thompson, Brodie, Acton, Gross, and others, showing that organic stricture of the urethra may depend upon certain highly irritating conditions of the urine, excessive venery, and prolonged sexual intercourse, gout, rheumatism, masturbation, etc., etc. Depending then, as it does, upon such a variety of causes, it is but just to infer that stricture is present in very many cases in which it has never been detected, and there would be a signal failure in attempting to detect it in any urethra of a capacity above 25 mm. in circumference, if governed by the limit in size of sounds recommended by Dr. Sands for common use.

The doctor then proceeded to the discussion of the questions, What amount of contraction is necessary to produce prolongation of gleet? and What degree of contraction is worthy of being called a stricture? In this connection allusion was made to the little obstructions, or wrinklings found in the urethra, which are detected by the passage of an instrument, and illustrated upon the urethral casts which have been exhibited.

These are capable of affording slight resistance to a free passage of urine, and are points at which the solid constituents of the urine may accumulate, give rise to irritation, inflammation, and subsequent thickenings of the mucous membrane. Now, suppose that two urethræ are invaded by gonorrhœa, one in the condition just alluded to, and the other one in which the mucous membrane offers no resistance to the complete passage of the urine, all things being equal, which would be the least likely to suffer from subsequent gleet? Manifestly the one which has offered the least resistance to the complete discharge of the urinary and other secretions. Dr. Otis does not regard the successive contractions shown in the casts of the urethræ exhibited as typical of a healthy canal, any more than half a dozen shrivelled hemorrhoids are indicative of a normal anal orifice.

Dr. Otis recognizes the fact, that in certain cases where stricture has been demonstrated to be present during life, the appearance of the mucous membane after death is apparently normal, and gives no evidence of the existence of contraction; but that by the passage of a bulbous sound the contraction is still recognized, thus indicating the locality of the stricture to be beneath and independent of the mucous membrane, and resulting from changes which are not necessarily cicatricial, but may be atrophy with contraction of the trabecular structure of the corpus spongiosum, or condensations of tissue in that vicinity, which may so nearly resemble the natural structures that the microscope fails to detect their true source and nature. Hitherto microscopic investigations have been directed towards the detection only of cicatricial

structures, associated with strictures, but the subject has not received from experts such attention as its importance demands. From whatever cause these contractions result, their effect is that of stricture, and they are amenable to the same methods of treatment.

With regard to the meatus, it was noted that not more than one in ten gives the test for the size of the calibre of the urethra, and it is therefore in no sense a guide to the urethral calibre.

One of the points insisted upon was, that localized contractions at any point of the canal, and from any cause, tend to embarrass the muscular structure, and render the subject liable to subsequent trouble, because of an imperfect expulsion of the urine, and a consequent retention of some of the solid constituents which become sources of irritation and consequent inflammation.

If, therefore, the obstacle is removed one of the predisposing causes to diseases affecting the genito-urinary tract is also removed.

Here Dr. Otis dwelt at some length upon the contracted meatus as a cause of various genito-urinary diseases, and concluded with the suggestive question: If relief follows division of this contracted portion of the urethral canal, is it irrational treatment, as claimed by Dr. Sands?

In discussing the question: What is the normal calibre of the urethra? reference was made to the investigations of Thompson, Sands, Van Buren and Keyes, Guthrie and others, showing the apparent want of harmony upon this point, for the standards laid down vary from 19 mm. to 40 mm. Amidst all this confusion the man who seeks advice of representative men concerning the condition of his urethra, will have given him an equal variety of diagnoses as to whether the canal is normal or stricture present. It is evident that some new method of examination should be brought forward. With this view Dr. Otis presents the doctrine that each urethra has an individuality of its own, and bears a definite ratio to the size of the penis with which it is associated. Dr. Otis does not desire to be understood as saying, that there is a mathematical exactness in this particular, but that it is a sufficiently trustworthy guide when the urethrometer is not at hand. In the tabulated report of 100 cases of normal urethræ examined by Dr. Otis, in company (on different occasions) with Dr. Stephen Smith, Dr. G. A. Peters, Dr. Bumstead, and several other surgeons, and presented to the society, the relative proportion between the penis and the urethra was shown not to vary more than 2 millimetres in 75 cases, and the average urethral calibre in 100 cases was 33 millimetres.

Concerning gradual dilatation, recommended by Dr. Sands as the best treatment for stricture, Dr. Otis regarded it as a temporary expedient, and that it should not be relied upon exclusively, nor should section be restricted to close strictures. Dilatation should be used as a temporary expedient (except as preparatory to urethrotomy), the same as demulcents and sedatives are used as preparatory treatment or for temporary relief in cases of vesical calculus not permitting of the more permanent relief by the knife or the lithotrite.

In concluding, Dr. Otis urged the necessity of the early recognition of stricture, and a prompt restoration of the urethral calibre, as a wise economy, rather than to treat the gleet, *which was a sure sign of stricture*, by injections, internal remedies, and bougies, until the obstruction had resulted in damage to important contiguous organs.

Dr. Weir proceeded to discuss the question under two heads:

1. What is the size of the normal urethra?
2. What are its normal contractions?

His conclusions were:

1. That the spongy portion of the urethra is the smaller and least distensible.

2. That a healthy urethra can be distended in its spongy portion to admit 32 to 33 mm., French scale.

3. Normal contractions frequently exist as small as 29 mm. in the spongy portion.

4. The normal size of the meatus varies from 18 to 28 mm.

5. That the urethral canal is narrowed at the meatus, dilated in the glans, slightly narrowed at the termination of the fossa navicularis, and then is nearly uniform in size through the spongy portion, again enlarges at the bulb, etc., etc.

Dr. Weir, in the course of his remarks, referred to cases in which there were evidences of stricture during life, but no evidences were found by microscopical examination after death.

Dr. Bumstead remarked that there were many questions in connection with the subject under discussion upon which he wished to have further light and more experience before venturing an opinion upon particular points. The truth in the case has probably not yet been found. But with reference to gleet and organic stricture the doctor expressed a doubt whether the former invariably depend upon the latter. He was not able to see any reason why we should not look for causes of a gleety discharge in a granular condition of the mucous membrane, hyperæmia at certain points, etc., such as are seen in chronic conjunctivitis or inflammation of other mucous membranes.

With reference to the use of the urethrometer, Dr. Bumstead regarded the feeling of fulness alluded to as a somewhat uncertain index, for it depends very much upon the sensibility of the patient, and also very much upon the care exercised by the surgeon. Dr. Bumstead agreed with Dr. Otis, and accepted the measurement of the central portion of the spongy portion, it being the least distensible, as the fairest index of the size of the urethra. How far that measurement corresponds to the size of the penis he was not prepared to say, although from the limited number of examinations he had made they had so far corresponded that he was willing to accept the statements made by Dr. Otis upon this point.

With regard to the size of the meatus, Dr. Bumstead differed with Dr. Sands, who regards it as a rough test to the calibre of the urethra, and considers the freaks of nature in this direction quite as constant as with regard to the length of the penis. We should never be tempted to take the size of the meatus as the index to the calibre of the urethral canal. He was of the opinion that, as a general rule, the meatus is smaller than the calibre of the urethral canal itself, and does not hesitate to divide it either for purposes of dilatation or for the purpose of passing instruments other than dilators.

With regard to internal urethrotomy for the cure of urethral stricture, as compared with dilatation, his experience had differed from that of Dr. Sands, and he did not regard dilatation as the best means to be employed. It is well known how unsuccessful the method of treatment by dilatation has been, for strictures submitted to dilatation have recurred time and time again, and that was the rule and not the exception. He had obtained much better results by internal urethrotomy than by dilatation or by rupture. Some years ago Dr. Bumstead was in the habit of treating

urethral strictures by the use of Holt's divulsor, but latterly he has discarded this method of treatment almost entirely. For the treatment of stricture in the anterior portion of the urethra, internal urethrotomy is rarely productive of harm, and has a great superiority over ordinary dilatation. He had also found that internal urethrotomy, when carried to a considerable extent has, in his hands, been productive of better results than when carried to a lower degree. Reference was made to several cases which had been cut so as to receive 26 French scale, and in the course of six months had so contracted as only to admit 14 or 15 of the same scale. These cases, cut a second time up to the same point, contracted a second time, and so on; so that during the last two or three years it has been his custom to cut up to 35 and 40 French, and the tendency to contraction has been much less than before. The same may be said with regard to the habitual use of very large sounds.

With reference to the statement made by Dr. Sands that instruments larger than 25 mm. were rarely necessary for purposes of treatment or diagnosis, he did not believe it could be carried out in practice. He was of the opinion that sounds larger than 25 mm. were constantly required in practice, and he should not feel satisfied if he restricted himself to that size.

With regard to slitting up the meatus, he was of the belief that it was done altogether too much, as well as cutting the urethra elsewhere, especially by the inexperienced. But he had seen no ill results from slitting the meatus, and did not hesitate to resort to the operation it necessary to effect the passage of an instrument. "I will say," adds Dr. Bumstead, "as I commenced, that the truth with regard to this matter under discussion is yet to be arrived at. The subject requires further investigation before we express a full and decided opinion as to exactly how far dilatation of the urethral canal should be carried."

Dr. George A. Peters, commenting upon the cases in which he had assisted Dr. Otis in making the measurements, remarked that he was surprised at the uniform correspondence between the actual measurement of the urethra and that called for by the circumferential measurement of the penis, the variation not being more than 1 or 2 mm. When using the urethrometer he does not depend upon the sensations of the patient, with reference to the distance to which the blades can be separated, but trusts to his own sense, and gives them sufficient separation, so that the instrument is barely grasped by the urethra without distending it unduly. At the meatus the instrument must be reduced in size two or more millimetres before it can make its exit, if it has moderately distended the canal before reaching that point.

With reference to slitting the meatus urinarius, he has had no trouble or fear in resorting to the operation, and has found it very essential for the purpose of perfecting the treatment of stricture, and sometimes for the absolute diagnosis.

He has failed sometimes in affording any relief when the meatus has been slit for the cure of what was supposed to be reflex trouble, but has never seen any actual harm arise from the procedure.

With reference to the use of instruments, the doctor remarked that he had carried them up to 35, sometimes 40, and was confident that he had obtained more permanent benefit than when they were carried only to 25 or lower.

With reference to the question of internal urethrotomy he agreed with Dr. Bumstead in the statement that it was to be relied upon for the treatment of stricture of the urethra rather than dilatation or rupture.

Dr. Keyes remarked that the fact that the urethra can be distended to very great dimensions has been known for a long time, but that this fact has any practical importance has not been shown.

So also the urethra will permit of extensive cuttings; but these, together with excessive dilatations, have fallen into disuse, thus showing that the profession has declared itself against extreme measures in these directions.

That the rectum can be dilated sufficiently to admit a man's hand, and the female urethra so dilated as to readily admit the index finger, does not necessarily make it the most judicious method of obtaining admission through these openings. Why any difference should be made respecting the male urethra he was not able to understand. That the measurements vary very greatly has been shown by the figures of every observer, and these variations which have been found in the calibre of the urethra, are enough to disprove the value of any instrument for its measurement beyond certain reasonably high limits. If anybody could establish the absolute calibre of this canal it would be valuable, but it seems difficult to obtain such a standard.

In the treatment of gleet by dilatation the doctor recommended that instruments below rather than above 30 mm. in circumference should be used, and stopped when the symptoms disappear. Dr. Keyes remarked that he had not used a sound for this purpose above the size of 36, and that size was used only once, and in a patient who had an exceptionally large urethra and penis. The symptoms of gleet cease almost always after the use of instruments below 30. In the anterior portion of the urethra internal urethrotomy is better than dilatation in the treatment of stricture. In the deeper portions of the urethra stricture does not yield to internal urethrotomy so readily.

Traumatic linear strictures are best treated by external section. And so it is; no fixed rules can be given with reference to the treatment of stricture, but every case must be studied by itself. To establish measurements, therefore, upon fixed standards which shall decide delicate questions with reference to operative interference or general treatment are apt to do more harm than good.

Reports of Hospitals.

BELLEVUE HOSPITAL.

Notes of Practice and Peculiarities of Treatment.

Typho-malarial fever—why not malarious.

This case illustrated the association of malarial with typhoid fever, and in it are found certain items of interest with reference to treatment and difficulties in diagnosis.

A male patient, aged 26, was admitted to the hospital Oct. 4th. He had been a moderate drinker, and when admitted had suffered from intermittent fever, "off and on," since July 6th. On Sept. 26th he had frequent, yellow, greenish discharges from the bowels, and on Sept. 28th he was obliged to give up his work, which was that of a hostler.

At the time of admission he complained of diarrhœa and chills, which he said had occurred every other day. The diarrhœa was relieved by forty drops of Squibb's diarrhœa mixture, and did not return.

On Oct. 5 his T. was 103° F., and he was placed upon extra diet (milk and eggs), and whiskey four ounces

every twenty-four hours. The stimulant was administered because the patient had been accustomed to the moderate use of it while in health, and it was continued throughout the course of the disease. At 10.20 A.M., Oct. 5, when the typhoid was suspected, his temperature was 102° F., P. 98, R. 24, and he received ten grains of quinine, having previously received twenty, but no effect was produced upon the temperature. From this hour a record was made almost hourly, day and night, of the T., P. and R., but only such report is made here as illustrates special features of the case.

At 1 P.M. a few spots of the characteristic eruption of typhoid fever were seen upon the abdomen. At 3 P.M. his temperature was 102⅘° F., and P. 75, which will illustrate the fact that the pulse cannot be relied upon to determine the presence of fever, but that the thermometer is necessary. Ten grains of quinine were administered by mistake, for it was determined to treat the pyrexia, in this case, by means of cold baths alone.

At 7.45 P.M. the temperature was 103⅘° F., and the man was placed in a bath having a temperature of 72° F., and kept in for fifteen minutes. The patient at first complained somewhat of a sensation of cold, but the relief which he received was so marked that he subsequently courted the bath rather than otherwise. At 8 o'clock, five minutes after removal from the first bath, his temperature stood at 98¾° F. The rule adopted was, that he should have a bath whenever the temperature reached 103° F. On Oct. 6th, at 1 P.M., the thermometer stood at 103¾ F., and he was at once placed in a bath having a temperature of 73° F., and kept in five minutes, and five minutes after his removal the temperature was 98⅘ F. At 5.30 P.M., the temperature had risen to 103½° F., and the bath was repeated as before; continued five minutes, and brought the temperature down to 98½° F. At 7 P.M. the bath was again repeated, and the thermometer fell to 99 F., after which the patient went through the night, the necessity for repeating the bath not arising. Oct. 7, at 9 A.M., the temperature was 100° F., P. 80; the general aspect of the patient was good; there was no diarrhœa, no delirium, no tympanitis of account, no tenderness in the right iliac region, and, exclusive of certain complications, the prognosis was good. Why was not this a case of malarial fever? There had not been so wide a range in temperature as is to be expected in remittent, there were no marked remissions, and there were no obvious manifestations of the malarial element after the administration of the forty grains of quinine. The eruption of typhoid was marked, although not abundant. It was thought quite probable that the malarious element would manifest itself in the way of a chill at about the time of convalescence.

TEMPORARY APHASIA AND HEMIPLEGIA.

The history of this case is brief, and its interest at once apparent. A male patient, æt. thirty, and an *occasional* drinker, had an attack of articular rheumatism one year ago. Three months after the occurrence of the rheumatism, he was attacked suddenly with aphasia and right hemiplegia, both of which soon disappeared, but that attack was followed by five or six similar ones during the course of one afternoon. Neither the hemiplegia nor aphasia remained for any considerable length of time. It was thought that these attacks were probably due to embolism affecting the middle cerebral artery or some of its branches. There was, however, no evidence of valvular lesion of the heart at the time of their occurrence, nor has there been since. Especial attention was then directed to the fact that emboli may come from collections of fibrin, so situated in the heart cavities as to prevent the production of a murmur because they are outside of the current as the blood passes through the organ. This fact is, perhaps, too much overlooked in making a differential diagnosis between embolism and cerebral hemorrhage as causes in any given case of hemiplegia, and it is doubtful whether the temperature of the patient will always enable the diagnostician to decide. decide. Peripheral paralysis, independent of the above, was also present.

Medical Items and News.

COLLEGE OF PHYSICIANS AND SURGEONS—COMMENCEMENT EXERCISES.—The sixty-ninth annual commencement exercises of the College of Physicians and Surgeons (Medical Department of Columbia College) took place on the evening of March 1, in Steinway Hall, and were attended by an audience composed mainly of the friends and relatives of the graduates, which filled every available part of the hall.

Prof. Alonzo Clark, president of the College, presided. The Hippocratic oath was administered to the graduates by President Barnard, of Columbia College, after which the degree of Doctor of Medicine was conferred upon ninety-three graduates. President Clark then delivered a short and sensible address to the graduates, giving them some useful hints in regard to the securing of professional success, after which Prof. Dalton announced the following prizes: First prize for thesis, $50, Abraham Mayer, New York; second thesis prize of $25, to David H. Davison, New York; Stevens triennial prize for the best thesis on the use of the application of the spectroscope in its relations to practical and scientific medicine ($200), to Dr. E. Rosenberg, New York; prize of $50 for best examination in anatomy to Frederic P. Griswold, Conn.; prize of $100 for best examination in diseases of children, to J. Augustus Walther, New York. For best clinical reports, Howard E. Wilson, of Mass., received a case of surgical instruments; Charles F. Stillman, of New Jersy, $50, and Edward B. Foote, Jr., of New York, a microscope; and George S. Knickerbocker, H. Ashland Clay, S. O. Vanderpoel, Jr., Alonzo Blauvelt, of New York, and Algernon T. Bristow, of Brooklyn, received honorable mention.

The Alumni Association prize of $400 was awarded to Dr. Thomas E. Satterthwaite, for an essay on the structure and development of connective substances.

Dr. Frederic A. Lyons, of the graduating class, delivered a valedictory poem, which was a very creditable and talented production, and was very flatteringly received by the audience.

Rev. Dr. Bellows made the address to the graduates, choosing for his subject, "Quackery in the Profession." The exercises were enlivened by appropriate music.

MEDICAL SERVICE AT THE CENTENNIAL.—There is is now being erected upon the Centennial grounds a building of some size, which is to be used as a medical headquarters. Two small wards—one for males, one for females—are to be attached, with beds, medical supplies, and everything in readiness for any emergency. At all times during the exhibition there will be a physician on duty in this building. Amidst the multitudes who will throng the Centennial there must be from time to time cases requiring immediate attention,

—sudden illness, accidents, and, if the summer prove a hot one, sunstroke, etc., etc.; so that the provision made seems to us a very wise forethought. No patients will be kept over night in the hospital, the beds being provided simply for the relief of cases of severity until they can be removed in the ambulance to their homes or some of the city hospitals. Some of our country brethren, mayhap even of our city confrères, will be glad to know that large and commodious offices will also be furnished in the building, in which the staff will be at all times happy to receive such physicians as may desire a few moments' rest from the toil of sight seeing.—*Philadelphia Medical Times.*

Death of Charles H. Clerke, M.D. At a meeting of physicians of Geneseo, on the 6th day of December, 1875, at the office of Drs. Wells and Antes, Dr. J. L. Shaw being chosen chairman, and Dr. H. T. Antes, Secretary, the following preamble and resolutions, as presented by Drs. Shaw and Wells, approved by a committee of Drs. Pomeroy, Brown and Hayden, were adopted:

Whereas, It has pleased the Ruler of life and death to take from his earthly labors and usefulness our friend and professional brother, Charles H. Clerke; therefore,

Resolved, That in the decease of Dr. Clerke the medical profession of Geneseo have sustained the loss of one of their best and most highly-esteemed associates—esteemed for his professional acquirements, his practical skill and success as a physician—esteemed for his honorable and upright character, his unvarying trustworthiness, his cordial bearing and loyalty to duty.

Resolved, That we will cherish his memory as a bright example of professional rectitude and private virtues worthy of our emulation.

Resolved, That in making post-mortem examination we are not influenced by idle curiosity, but by the positive request of deceased, and for the cause of science and humanity.

Resolved, As an emblem of our respect for the deceased and family, we will wear crape on the left arm for thirty days.

Resolved, That a copy of these resolutions, signed by the medical profession of Geneseo, be transmitted to the family of deceased, with the expression of our heartfelt sympathy in their great bereavement.

Resolved, That these resolutions be published in the papers of the city, and a copy sent to his aged mother, and that a notice of his death be forwarded to The Medical Record, of New York City.

Signed, Dr. J. L. Shaw, Dr. S. T. Hume, Dr. D. L. Machesney, Dr. Ira R. Wells, Dr. Enos Pomeroy, Dr. W. C. Brown, Dr. Wm. Hayden, Dr. T. H. Fulton, and Dr. T. H. Antes, Secretary.

Geneseo, Henry Co., Ill.

Free Hospital for Children.—The last annual report of this institution shows a total number of ninety-six patients treated. The medical staff is as follows: Consulting Physicians, Austin Flint, Sr., M.D., and Alonzo Clark, M.D. Consulting Surgeons, George A. Peters, M.D., and Erskine Mason, M.D. Attending Physicians and Surgeons, Robert Watts, M.D., and Charles T. Poore, M.D.

The Society have purchased the building they now occupy (Thirty fourth Street and Eighth av.) for $30,000. The hospital is intended for the exclusive reception of children, and it is always to be entirely free to the helpless little ones. One of the means taken to raise the required amount of purchase money, and at the same time give the children a proprietor's interest in the building, is to ask each child to contribute one brick. The cost of a brick when in position is estimated at ten cents, and it is desired to have 350,000, equivalent to $35,000. An illuminated card will be presented to each purchaser of a brick, signed by Bishop Potter and the Treasurer, stating that he (or she) "has placed one brick in St. Mary's Free Hospital for Children." Although this plan has been originated quite recently, 10,000 bricks have been subscribed, and the popularity of the scheme with the Sunday school children is such that no fears are entertained of its ultimate success. It is also desired to establish a training-school for girls. A modest beginning, under the Sisters of St. Mary, has already been made in the present building, and it is hoped that ere long they will have a more suitable house, provided with all the necessary and systematic arrangements.

Trichinous Pork.—The Scientific Committee to the Prussian Ministry of Medical Affairs have recommended a method of disposing of and utilizing the carcasses of condemned hogs. They assert that the fat can be used as lard without danger if it is melted out of its tissue by roasting; and as it would be dangerous to bury the deceased meat, for fear of the infection of other animals, they recommend that it be boiled down for the manufacture of soap and glue.

The Medical Society of the County of Kings (N. Y.) intend to publish their proceedings monthly in pamphlet form.

Charges to Clergymen.—A correspondent from Boston writes: "An item in The Medical Record of March 4th, concerning charges to clergymen, reminds me of personal experience.

I once attended a child of a clergyman for some weeks. The child was anæmic, and after considerable attention was brought up to the health line. I was asked what my bill was. I replied, "Nothing."

Some weeks afterward I was surprised to find that the family had engaged another physician, who never failed to charge every patient and get his money. I expressed my surprise to an intimate friend of mine, who replied: "If you will not mention it, I will state that the clergyman's wife, in a conversation with my wife, said: 'We employed Dr. ——— to attend Mary, but he didn't charge anything; so we concluded that he could not be good for much, and now that Henry is so very sick we concluded to employ Dr. ———.'"

T.

French Prizes.—The *Grand Prix Montyon de Médicine et Chirurgie*, valued at 10,000 francs, was taken by M. Onimus, his subject relating to investigations on the application of electricity to therapeutics.

M. A. Guerin also received a prize of 2,500 francs for an article showing the value of cotton dressings in the treatment of wounds.

MM. Bergeron and Hôte received 2,000 francs for a work on poisoning by the metallic poisons.

M. Rigaud received the *Prix Barbier* (2,000 francs) for his articles on the treatment of varicosities in the lower extremities and varicocele.

Professor Chauveau, of Lyons, received the *Prix Lacaze* (physiology) for his investigations in the domain of virulent diseases.

The *Prix Bienaimé* (20,000 francs) given for the discovery reflecting most honor on the country or of most value to it, was given this year to M. Bert for his works illustrating the influences which the modifications of barometric pressure exercise on the phenomena of life.

Medical Advertising.—Concerning a recent reference to his paper on the above subject, Dr. Fields writes:

"It was presumed that the clandestine newspaper advertising that gave occasion for the article entitled "Doctors and Newspapers" was confined to this locality, but as "some of our New York brethren are so well versed in this business that they can give Dr. Fields a great many useful hints," the closing paragraph of the article may have more general application.

"And instances are not wanting, where the exploits of aspiring members in good standing in our own profession, have been the subject of extravagant newspaper notices. Such occurrences are always 'unavoidable' or 'accidental' or 'very mortifying to the pride' of the recipients, but if a revision of the code should remove the occasion for the lying there is about such matters, it is fair to presume that among other benefits, would be that of improving professional morals."

A New Pair of Siamese Twins.—At a recent meeting of the New York Pathological Society, Dr. John E. Blake presented a pair of infants joined after the fashion of the Siamese twins. The specimen was merely loaned to him by a gentleman who had purchased it for the Anatomical Museum at Sweden. The twins (females) were born in Tobasco, a town in Mexico, are reported to have lived nine days, and to have weighed 15 pounds. The mother was an Indian and the father a mulatto. One twin showed the characteristics of the former race and the other of the latter. In this connection it is well to state that the *Students' Journal and Hospital Gazette* (London, Feb. 12) reports a similar case. "The wife of a carpenter residing in Hastings was delivered of twins (girls), who were united by a cord or ligament of flesh drawing both breasts together." The infants, who were well developed and possessed pretty features, did not survive their birth. The case has attracted some attention among medical men in that place, and photographs of the twins have been taken.

The Eucalyptus in the Campagna.—A paper was recently read before the London Pharmaceutical Society, wherein the following statement was made: In the Campagna, some three miles from Rome, a century or so ago, there was a village containing various churches and a monastery, which had to be abandoned on account of the malaria. Up to 1869 or 1870 the churches there were in ruins. Six years ago two French Trappists planted the *Eucalyptus globulus* in the village, some of the trees having now attained a height of thirty feet. For the last two years the monks have inhabited the ruined convent without suffering the least inconvenience, using, from time to time as a febrifuge, a decoction made from the leaves of the tree. Italian botanists and physicians are urging the Government to plant the *Eucalyptus* in quantity in the Campagna, believing that by its means these deadly plains may be restored to that flourishing condition they had onceattained during the periods of early Roman history.

Overcrowding in our Schools.—The subject of overcrowding in the public primary schools is engaging the attention of one or two of our leading secular papers. One of the latter is publishing elaborate reports of visits to the different schools in question. We hope they will have the effect of drawing the attention of our legislators to the expediency of increasing the accommodations of the little ones.

Milk the Cause of an Epidemic.—An epidemic of typhoidal character has just broken out in a small Lancashire village of some 500 inhabitants, where 150 people were taken ill. It was quite conclusively shown that the poison came from milk which had been furnished by a sick cow.

A Medical Lord Mayor.—The present Lord Mayor of Dublin is Dr. G. B. Owens. The *Medical Press and Circular* says of him: "In ascending the mayoral chair Dr. Owens has shown a beneficial example both to his metropolitan brethren and the citizens of Dublin, for he has proved that active medical practice is no bar to the praiseworthy discharge of public duty, and that the claim of a physician or surgeon to civic honor will be recognized by the citizen whenever high social qualities accompany administrative ability."

Double-Headed Diplomas. — A correspondent from Carthage, Ill., writes: "In your issue of Feb. 26th, you mention 'a new time-saving method of securing a diploma,' and credit those Siamese twins institutions at Louisville, Ky., with inaugurating it; but the credit (?) for this innovation belongs farther west. The College of Physicians and Surgeons of Keokuk, Iowa, has had a winter and summer course of lectures in operation for three or four years past, and grants diplomas after an attendance on the two courses, so that a student may commence attending lectures in October and graduate in the following May."

Diphtheria.—Mr. Edward Garraway (*Lancet*, Feb. 19) says that in the earlier stage of the deposit of this disease, "a single painting with a strong solution of nitrate of silver will effectually destroy the parasite and rescue the patient."

Army News.—There have been no changes of stations or duties of medical officers of the army for week ending March 4, 1876.

Vivisection.—The Royal Commission on vivisection have made a report, in which they have come to the conclusion that the use of animals for experiments is not by any means so cruel and reckless as has been alleged. The Secretary of the Royal Society for the Prevention of Cruelty to Animals has now acknowledged that he does not know of a single case of wanton cruelty, and the Commissioners themselves report that a general sentiment of humanity on this subject appears to pervade all classes in the country. They are opposed to any legal enactment for the prevention of any physiological experiment, and maintain that such experiments before medical classes are necessary and legitimate if performed with anæsthesia. In conclusion, the Commission recommend that vivisections be placed under the supervision of the Home Secretary, by means of a system of licensing and registration.

DIPHTHERIA.

CONDENSED FROM LECTURES DELIVERED IN JEFFERSON MEDICAL COLLEGE, ON MAY 13TH, 17TH, 20TH, AND 24TH, 1875.

By J. SOLIS COHEN, M.D.,

LECTURER ON LARYNGOSCOPY, AND DISEASES OF THE THROAT AND CHEST.

PART V.

SEQUELÆ.

The paralyses that occur during convalescence, or after its establishment, or after the height of the disease has been passed, are indicative of a profound morbid impression on the nervous system. This impression is in some respects characteristic, although similar paralyses are found to occur after other severe specific systemic affections, as small-pox and typhoid fever. The amount and intensity of these paralyses of diphtheria are by no means directly proportionate to the severity of the affection.

The palate is the most frequent, and usually the earliest seat of the paralysis. It is seen to be relaxed, and does not contract upon contact with it of instruments or stimulus. The results are difficulty of swallowing, regurgitation of fluids through the nose, and an altered (so miscalled nasal) tone of voice. It seldom occurs before the third or fourth week of the disease, although it has been noted as early as the ninth day. Cutaneous diphtheria is sometimes followed by the same sort of paralysis of the palate, a significant fact indicating that the impairment of nervous force is due to systemic poisoning rather than to any local effect upon the peripheral terminations of the affected nerves themselves.

The pharynx, and, to some extent, the œsophagus also, are sometimes paralytic after diphtheria; under which circumstances the difficulty of swallowing is still greater, so great sometimes as to necessitate feeding through a stomach tube. Vomiting, however, may occur even after swallowing is impossible. The nerves of the larynx may be paralyzed, in which case there will be impairment of voice, constriction of the glottis, or immobility of the epiglottis, according to the nerves impaired. Laryngeal paralysis, favoring the escape of food into the air-passages, necessitates the use of the stomach tube. Constriction of the glottis would be an indication for tracheotomy. The nerves of respiration are sometimes impaired, and we have dyspnœa or apnœa in consequence, so that the institution of artificial respiration may be temporarily requisite from time to time. The cardiac nerves may become implicated, a manifestation, often, of fatal significance, the activity of the heart diminishing to from sixty to forty pulsations in the minute, or down to thirty, and even below that before death.

In addition to these manifestations there may be impairment of the organs of special sense: taste, smell, hearing, and vision. In fact the paralyses may be manifested in any of the organs and muscles in which paralysis is manifested under other conditions.

The treatment of the paralyses following diphtheria consists in the use of the ordinary methods of invigoration—fresh air, baths, and tonics—under the influence of which the nervous system gradually undergoes recuperation, and the paralyses subside. Should this not be the case, the use of strychnia and of phosphorus are indicated, while local applications of the electric current are calculated to hasten the progress of restoration to normal function. Symptoms of paralysis sometimes remain for several months after convalescence from the diphtheritic manifestations. Occasionally they are insusceptible of amelioration, and if important functions are interfered with they may be the direct cause of death, as in paralysis of the respiratory organs, the heart, and the pharynx and œsophagus.

COMMON MEMBRANOUS SORE-THROAT.

It would be improper to conclude these lectures on diphtheria without alluding to a non-specific diphtheritic sore-throat, which is often confounded with diphtheria. The local manifestations are similar to those of diphtheria, but their mode of origin is different. Under general subjective symptoms of ordinary catarrhal sore-throat, small vesicles form upon the palate, tonsils, or pharynx, the contents of which become turbid. These vesicles either subside in two or three days, without leaving traces of their presence, or they rupture, leaving small ulcers, which soon become covered with a plastic exudation which spreads and coalesces with other patches which have commenced in the same manner at other portions of the surface.

The prognosis is favorable, the affection subsiding spontaneously in a week or ten days; though it is occasionally fatal, in children, from extension of the pellicle into the air-passages.

The treatment consists in the administration of tonics constitutionally, and the local use of alum, borax, or mild astringents when required.

In the presence of epidemic diphtheria, it would be very difficult to distinguish a case of common membranous sore-throat; and in case of doubt the better plan would be to treat the case for diphtheria, as unnecessary activity would not be productive of injury. But when these cases get well, as they almost always do, we must avoid recommending for diphtheria some inefficient remedy, during the use of which a case of common membranous sore throat has gotten well spontaneously. Much of the success attributed to some of the remedies highly lauded in diphtheria has been due to their employment in unrecognized cases of common membranous sore throat, by no means an infrequent affection, in large cities, at all seasons.

A CLINICAL CONTRIBUTION TO THE ETIOLOGY OF ACUTE CARDIAC INFLAMMATIONS.

By EDWARD J. BERMINGHAM, M.D.,

NEW YORK.

It is thought that the following cases will be of interest, as bearing upon a point doubted by a large number of the profession, viz., the occurrence of acute cardiac inflammation as a primary idiopathic disease.

Case I. *Acute Primary Idiopathic Endocarditis.*—On December 11th, 1875, I was called to see M. K., æt. 50, widower, cloth-presser by trade, who related the following history:—Until ten days ago he had enjoyed perfect health, hardly knowing a sick day throughout his life. His habits have not been of the best, as he has been a steady drinker, and would im-

bibe to intoxication a couple of times monthly. Has never used tobacco. Ten days since he returned from his business as usual, enjoying the best of health, and not under the influence of any stimulant; and, after building his fire (he lived alone and was his own housekeeper) was seized with severe pains in the præcordial and epigastric regions. These pains he described as feeling as though knives were passing through him. From this time he began to complain of his heart troubling him, and a slight cough developed. A physician was called in, who prescribed for the patient, but made no subsequent visits, and, in consequence of his neglect, I was sent for to-day. I found the patient to be an extremely nervous and irritable individual, easily excited, and considerably annoyed about his condition, which did not improve in the least, and caused him to pass many sleepless nights. An examination of the lungs revealed râles over both, anteriorly and posteriorly, respiratory sounds about normal, and slight dulness on percussion. Heart beating so irregularly and rapidly that the sounds were not distinguishable, but there seemed to be a roughness of both. Pulse could not be counted, about 180. Tenderness on pressure and pain in epigastric region. Bowels loose. Nausea at times, but no vomiting. Eructations. Liver neither enlarged nor tender. No œdema of extremities. Urine examined and found to be normal. Ordered mustard leaf over epigastrium, Tr. digitalis x., quin. sulph. gr. ii., every three hours; sleep to be procured by hydrate of chloral; and light but nutritious diet.

Dec. 13th. To-day the patient is much more composed, and is entirely free from pain. Heart slightly improved, but still very rapid and irregular. The roughness spoken of above is more perceptible, but no murmur can be detected.

Dec. 14th. Dr. J. J. Henna saw the patient in consultation to-day. He could detect no murmur, but the pulse-tracing by Marey's sphygmograph, in the use of which Dr. Henna has had a large experience, indicated *mitral regurgitation*. Pulse 130. Lungs in the same condition.

Dec. 31st. General anasarca has gradually developed, and at present is very distressing, as well as the œdema of the lungs. Of late the urine has contained a trace of albumen. Hot air and vapor baths, and diuretics and cathartics make no impression. The pulse has been brought down to 80 by the digitalis, and at present it is very little out of the way as regards regularity. To-day Dr. S. A. Raborg was called in consultation. He could detect no murmur, but only roughness of the heart sounds. The treatment was continued.

Jan. 10th, 1876. Pulse 60, and regular. Condition otherwise unchanged.

Jan. 20th. Condition the same. Patient suffers a great deal from the distressing cough, and his whole cry is for its relief. An examination of the heart to-day (the first for three weeks) revealed a loud blowing murmur, heard with and following the first sound, most distinct at the apex. The patient and his friends were anxious to have an expression of opinion in regard to the prognosis of his case, and I accordingly explained to them, as well as I could in untechnical language, his exact condition; and held out no hope whatever of an ultimate complete recovery. He and his daughter, the parties most immediately interested, expressed themselves as perfectly satisfied that the case should remain in my hands, and that all that was possible would be done for the patient. A few days later, however, I learned that a doctor had been called in, and had substituted another line of treatment, from which he promised the patient a complete cure in between five and six weeks. The treatment which I had adopted throughout consisted of diuretics, diaphoretics, cathartics, and tonics. A hot-air bath which I had procured for the patient was removed by the attendant in payment or part payment of fees, and the poor fellow was thereby deprived of about the only means of producing a healthy action of the skin. These facts were related to me by the patient himself.

The subsequent history of the case is related in a few words. The patient did not improve under the new treatment, but failed gradually, and died quietly on February 17th, 1876.

The first point of interest is in respect to the diagnosis. During the first part of the period in which the case was under observation it was regarded as a functional disorder, notwithstanding the roughness of the heart sounds, which was thought to be due to a chronic affection of the valves arising from the irritation of alcohol (the man had been a steady drinker), and besides it was not sufficient to give rise to such a marked disturbance. The sphygmograph pointed to the nature of the trouble in the earliest stage of the affection, but as the physical signs did not agree with it its testimony was cast aside. In fact, it was not until the mitral regurgitant murmur had developed so as to be audible that the case was comprehended as one of acute endocarditis. Of this there cannot be a doubt, as the murmur was most decidedly developed while the patient was under observation. Such being the case, it is an interesting fact, and one of value also, that the patient had never suffered from rheumatism, and therefore the testimony offered by this case is contrary to that generally laid down in text-books, viz., that acute endocarditis seldom or never occurs as an idiopathic affection.

Case II. *Acute Primary Idiopathic Pericarditis.*—L. S., æt. 17, employed in book-store. A couple of days since became overheated while carrying in some books from the sidewalk, and as a consequence perspired freely; while in this condition he was suddenly chilled, and during the evening of the same day had several severe chills of short duration. Pain in the præcordial region and fever succeeded, and this evening (January 22d, 1876) I was sent for. I found him in the following condition: Pulse, 132; temperature, 102¼° F.; pain and oppression in cardiac region, which is increased upon pressing upwards from the epigastrium, and is then aggravated by pain on the left side of neck; dyspnœa; countenance somewhat anxious; slight epistaxis; occasionally a cough. Physical examination revealed a few râles here and there over both lungs, anteriorly and posteriorly; lungs otherwise healthy. Over heart was heard a double friction sound, synchronous with the cardiac pulsations, which was increased upon the patient holding his breath. Area of cardiac dulness not increased. Ordered application of emplast. cantharid. over seat of pain; a laxative; quin. sulph. gr. ij., tr. ferri chlor. ℥v., every three hours, and U. S. liq. morph. to be given in sufficient quantity to relieve pain, say ʒ i. every three hours, alternating with the quinine and iron; and port wine. A few days later, as the pericardial friction sound was supplemented by the effusion into the pericardial sac, a pleural friction sound was manifest in the left mammary region. The signs of pleuritis developed progressively, and ammon. muriat. was added to the treatment. In consequence of the gravity of the symptoms, I requested a consultation. Dr. J. A. Monell was accordingly called in, on February 5th. At this time there was bulging of the whole left side, dulness on percussion, and bronchial breathing. Res-

piration labored; pulse, 112; temperature, 102¾ F.; respiration, 42; heart laboring. Dr. Monell concurred in the diagnosis—acute idiopathic pericarditis with effusion, and acute pleuritis with effusion—and we decided upon the following course:

℞ Quin. sulph..... ℥ i.
Tr. ferri chlor..... ℥ ij.
Ammon. muriat..... ℥ iss.
Pot. iodidi..... ℥ iij.
Aquæ, q. s., ad..... ℥ iv.
M. Sig. teaspoonful every three hours.

Inf. digitalis (gr. x.–gill) ℥ i., three times daily. Counter-irritation to be kept up by

℞ Ol. tiglii..... ℥ i.
Ether. sulph..... ℥ iij.
Tr. iodinii..... ℥ iv.
M. Sig. externally.

Opium and wine as indicated, and nourishing and concentrated food.

March 5. The treatment has been varied as the symptoms indicated, and the patient has not had an unfavorable sign. For the past two weeks the pleuritic effusion has been disappearing quite rapidly, until at present it is almost entirely gone. The cardiac effusion, however, is much slower in being absorbed, although it is progressing as well as can be expected. Pulse ranges from 100 to 105; temperature, 99° F. Skin, bowels, kidneys, and stomach acting admirably.

This is one of those rare but unequivocal cases of pericardial inflammation occurring in a previous healthy person. It cannot be regarded as complicating the pleuritis, as both diseases progressed at about the same time, and in the early stage the symptoms of the cardiac trouble were by far the most prominent.

It is hoped that these cases may be of some little value as evidence of the fact of cardiac inflammations occurring as primary idiopathic diseases.

243 West 53d Street, New York.

RESECTION OF THE RADIUS FOR NON-UNION.

By LE ROY McLEAN, M.D.,

SURGEON TO TROY HOSPITAL.

John B., aged 30, received, April 30th, 1875, a fracture of both bones of the forearm, through their middle third, while adjusting a belt over a pulley in a planing-mill where he was employed. The fracture was reduced, and dressed with front and back splints, but at the end of nine weeks it was found that union of but one bone, the ulna, had taken place.

The limb was then put up in a plaster-of-Paris bandage, reaching to the elbow, which was removed in sixty days with no better result. August 28th, twenty weeks from date of injury, he was brought to me for treatment by his attending physician. I faithfully but fruitlessly tried friction of the ends of the fragments, and Brainard's perforators, with a like result, and as a last resort resolved to excise the ends of the bone and retain them in position by means of silver wire.

The operation was performed November 30th, as follows: The patient having been placed under the influence of ether, an incision three and one-half inches long was made on the outer side of the arm, parallel to the bone, and over the seat of fracture, and the parts exposed.

The ends of the bone, which overlapped each other, were covered with a tough fibrous membrane. This, with a portion of bone, was removed with bone forceps, no effort being made to preserve periosteum, when, finding that the extremities could be nicely approximated, they were drilled with a small Brainard perforator, and a double silver wire introduced to keep them in apposition.

The wire was then twisted and allowed to protrude from the wound, which was closed by three sutures. Splints and a roller being applied, the patient was put to bed and an opiate administered. The operation was followed by little or no local or constitutional disturbance.

The wound healed kindly, without much suppuration, and at the end of a week he was able to visit my office. The limb was examined and redressed at stated intervals, and eleven weeks from date of operation the wires were removed, when perfect union had taken place.

Original Lecture.

ON THE DIAGNOSIS AND TREATMENT OF CHRONIC SCALY ERUPTIONS OF THE PALM OF THE HAND.*

By L. DUNCAN BULKLEY, A.M., M.D.,

PHYSICIAN TO THE SKIN DEPARTMENT DEMILT DISPENSARY, NEW YORK.

There are three (and but three) forms of scaly disease liable to affect the palms of the hands, which are very similar in appearance, very apt to be confounded or mistaken for each other, and yet which require widely dissimilar treatment. These three are: I. *Eczema palmare;* II. *Psoriasis palmaris* (non-specific); and, III. *Syphiloderma palmare*, or chronic scaly syphilide of the palm.

The importance of correctly differentiating these diseases can hardly be overestimated, and yet I presume that there is no one who sees much of cutaneous disease who does not continually meet with cases of one or other of these affections which have been wrongly diagnosticated, and consequently wrongly and ineffectually treated for months, perhaps for years. We have now attending at the Dispensary three cases exhibiting these three forms of disease, and a brief detail of them will establish more clearly than in any other way the essential peculiarities of each, and a close comparison of the lesions will lead one to wonder how they could be taken one for the other; and yet this is constantly done, and may readily happen when each disease is considered alone and not compared in its elements with those most resembling it. The cases are as follows:

Case I. *Eczema palmare.*—This woman, aged twenty-six, bringing two healthy children with her, presents a palmar eruption which so much resembles that produced by syphilis that casual observation might mistake it for such, but careful study will show, I am sure, that there is abundant evidence that syphilis is not the cause of the lesion before us. First, then, observe that both hands are almost symmetrically affected; now, while the earlier eruptions of syphilis are generally symmetrical, lesions occurring late in the disease are wont to be unilateral, and rarely do

* Cases shown and remarks made in substance to pupils at the Demilt Dispensary, New York.

we see both hands similarly occupied by the syphiloderma of the palm. The gummata and bone lesions of syphilis appear to be influenced largely by local causes, and I have often thought that these late scaly eruptions on the palm had, as their starting-point, some local cause, the continuance of which may tend to cause the latent poison to concentrate there. In this case, then, the almost precisely similar appearances of both hands rather speak against syphilis. But, second, on further questioning we find that the patient has had the eruption for three or four years; that it comes and goes, perhaps several times in a season, being worse, as a rule, in the spring and autumn, and that its severity depends very much upon the amount which the hands are used in washing. A curious feature also is that she is not troubled with the eruption when pregnant, but when nursing, the disease is always worse. These elements speak against syphilis, but weigh greatly towards an eczematous nature of the affection. Let us now see what can be learned from the appearances of the eruption.

The left hand is most affected, and its state may be thus described. A considerable portion of the palm is bereft of its normal epidermis, is slightly reddened and somewhat scaly. I say *somewhat* scaly, because you see quite a portion of the skin, where the normal furrowing of the epidermis seems to be present, without any scaling over it; but even here the abnormal redness and the thickening felt on pinching a fold of skin between the fingers shows that there is yet trouble beneath, and these portions will sooner or later scale again unless prevented by treatment. The edges of the eruption are sharply cut, the healthy epidermis at the border standing up abruptly, almost as if cut with a punch, a state not seen in syphilis in this place: the whole of the skin of the palm is thickened pretty uniformly, and there is some cracking at the lines of motion: finally, she says that the affected portions at times discharge serum. The diseased surfaces often itch excessively.

We will shortly see how these clinical features differ from those presented by the case of palmar syphiloderma, but let us first examine another similar eruption presented by

Case II. *Psoriasis palmaris* (non-specific).—Non-syphilitic psoriasis of the palm is very rare; indeed some writers have indicated that it does not occur except when associated with psoriasis of other parts, in which case, of course, the diagnosis is comparatively easy. There can be no doubt, however, of the existence of true psoriasis affecting the palms alone, and the case before us presents features different entirely from eczema, on the one hand, and certainly not due to syphilis, for there is absolutely no corroborative history of the latter disease, and clinically it in nowise resembles either.

I must here say that when I used the term *non-syphilitic psoriasis*, I did not intend to imply that true psoriasis can ever be of syphilitic origin, or that the scaly eruption due to that poison should ever be called psoriasis; the expression was used because the term palmar psoriasis has very generally been applied to the eruption of syphilis, whereas I wish to claim it solely for the true disease. It is a great error, which has crept into dermatology, this using the name of one disease adjectively to express a quality of another. We may have pustular, squamous, or vesicular lesions of the skin due to syphilis, which may resemble acne, psoriasis, or eczema, but it is improper to speak of syphilitic acne, psoriasis, or eczema, nor should the term syphilitic lupus ever be applied to any of the forms of tubercular syphiloderm; great confusion must necessarily arise from such a confounding of terms.

To return to our case of palmar psoriasis. Both hands of this man, aged twenty-eight, are covered on their inner surface with a scaly eruption made up of isolated spots of different sizes, some of them touching each other where the normal epidermis is wanting. These spots are mostly circular, varying in size from one-twelfth to one-half of an inch in diameter; the surface of each one is covered with a moderate amount of scale which can be picked off, beneath which the surface is reddened, but there is no sign of exudation. On pinching up the skin you see that there is not the thickening observed in the former case, the eruption has never exuded moisture, and itches but moderately at times. Moreover, here, where the disease extends slightly on to the wrist, the characters resemble somewhat the ordinary psoriasis, certainly more than they do those of eczema, the eruption being in circles, and these scaly crusts, although not typical of psoriasis, are more light, flaky, and easily detached than in eczema. Now, while I do not know of microscopical investigations to establish the identity of this form of eruption on the hands with psoriasis as ordinarily observed, I hold that its clinical features resemble that disease rather than eczema, and, in addition to accuracy of diagnosis, I am always desirous of robbing eczema of all that I rightfully can, for at the best the term is used to designate phenomena differing vastly in appearance. The reasons, then, for establishing such cases as this as psoriasis, and not eczema, are these: the absence of itching, exudation, cracking and thickening, and the distribution of the eruption in small, round, clearly defined spots, as opposed to the single larger patches of eczema, the scaling representing at the same time that in psoriasis, altered here by the thickness of the epidermis.

Look now at the eruption affecting only the left palm of this next patient, who has been in attendance some time with constitutional syphilis, and quite a different picture is presented.

Case III. *Syphiloderma squamosum palmare.*—This man, aged thirty-eight, exhibits, as you see, on the right leg an unmistakable tubercular eruption of syphilis, his tongue presents a characteristic appearance of late syphilitic mucous ulceration, while here on the inside of the left hand there is a lesion which, with experience and study, should speak quite as plainly of the results of syphilitic infection. The date of his inoculation is unknown, as he has been repeatedly exposed with occasional venereal infections; the sore which resulted in the syphilis may have been within five years, though I have seen just such palmar syphilis twenty years after infection.

The clinical features of the eruption on the hand may be thus described. On the left palm there is a patch of diseased skin irregularly circular, of nearly two inches longest diameter, extending from very near to the radial border of the ball of the thumb to about the middle of the hand. The entire integument covering this is in a roughened state, peeling off in places, especially at the edges; the whole surface is darkly reddened, and where the epidermis has come off the color is of a more livid purple. You will notice that there is very little if any thickening in the centre of the patch, where the disease seems to have expended itself; but here on the edges there is a moderate thickening and elevation, the result of the specific infiltration of tissue. The eruption does not itch at all, and gives no annoyance except its unsightliness, though this latter is not always the case, for I

have seen palmar and plantar syphilitic patches crack and bleed and give great pain.

You will bear in mind that such a patch as we are looking at is one of the late manifestations of syphilis, not infrequently it is the only one after many years of immunity, and it is quite different from the acute congestive eruption on the palms and soles of that young man now in attendance, with the profuse, general, large papular syphilide, now only six months after infection. There, you will remember, the patches are smaller, are numerous, round, and resemble those on the rest of the body, except that the epidermis being thicker in these situations there is less elevation and a less marked discoloration in him. When he first came under treatment many of the spots on the soles of the feet were ulcerated by the pressure and maceration, and he walked with great difficulty.

Let us now take this little group of cases and analyze the histories and appearances of the lesions. The eruption in the first case, that of the woman with eczema, affects both hands, the palms are thickened, itch excessively at times, and at times discharge serum, and are almost continually cracked. In the second case, which I have described as psoriasis, the disease remains in isolated patches which scale continually; they are mostly circular and never exude, they itch but seldom, and then not greatly, and both hands are also very similarly affected. On our syphilitic patient the eruption affects but one hand, the disease is in one large patch, as is generally the case, it is and always has been dry, has steadily increased from a small spot to its present size, the scaling is inconsiderable and the margin is not evenly laid out, but is of irregular outline; moreover, the portion denuded of its full share of epidermis is of a dark purple red color. On close examination the eruption is further found to be composed at the margin of a number of separate elements, for while eczema and psoriasis enlarge by peripheral augmentation of smaller patches, the eruptions caused by syphilis are made up of an *aggregation* of smaller portions, the cutaneous lesions of syphilis, as you know, having a tendency to assume circular forms.

Thus far of the visual appearances of the diseases offered for our differentiation, but the histories of the cases afford us ample aid as well. The woman has had her eruption for three or four years, it comes and goes, is worse in the spring and fall, and, moreover, depends very much upon the use or abuse of the hands, and on her physical state: she has never had any other eruption and gives no history of syphilis, and furthermore, brings two healthy children with her, all she has ever had, and having never had any miscarriages. The man with the psoriasis of the palms has had the disease several years, gives likewise no syphilitic history, and has had no other eruption. It is always well to examine the whole body where there is uncertainty of diagnosis, for there might exist some evidences of past or present eruption which would materially assist in diagnosis, and as before remarked, in most cases of psoriasis of the palms there will be found patches elsewhere of the disease. In our last case—the syphilitic—the other symptoms are so very pathognomonic that a mistake would be unpardonable. I remember well Bazin, when showing a case of palmar syphilis at St. Louis, Paris, looked at once at the tongue, and finding a mucous ulceration there, remarked, that when a suspicious lesion on the tongue coexisted with one on the palm, syphilis must be very strongly suspected, a point which I have verified and pointed out again and again.

We will now consider for a moment, with reference to treatment, the disastrous consequences of a mistake in the diagnosis of these cases. Apart from the wrong done, and perchance distress occasioned by ascribing syphilis as a cause of disease where it does not exist, the measures appropriate for one would not only fail to do good, but would probably do very positive injury to the others.

The prognosis, too, varies greatly with the diagnosis. In the last patient we can assure a perfect and quite speedy cure—I have seen palmar syphilis disappear within two weeks after a course of treatment had been entered upon; the second patient must have a rather more unfavorable prognosis, for it will certainly take longer to remove these hard almost horny masses of the palmar psoriasis, and the measure of success will depend very much upon the faithfulness of the patient. In the first case, of chronic eczema of the palms, the prognosis is more doubtful yet, and must be very guarded. The disease has already lasted three or four years, getting better and worse; the patient is a mother of a family, as you see, in the humbler walks of life, and must use the hands constantly in washing and over the fire, and she very probably will not or can not give the care necessary for her cure. As soon as the hands get a little better she will neglect treatment, and if she does, the disease will as surely relapse as a ball will tend to run down an inclined plane, if in pushing it up you stop anywhere short of the top. Had she the syphilitic disease, or rather, were this a case of palmar syphilis, the prospect would be brighter, for internal medication will remove that lesion even under the most adverse circumstances. The fact of our third patient having had his hand trouble several months does not diminish the prospects of his cure, whereas the years which have gone over this woman's eczema have quite another meaning.

The treatment of these three cases will likewise differ widely according to the diagnosis. The woman's hands require a moderate stimulation combined with soothing measures and internal remedies, especially arsenic, iron, and alkalies, together with cod-liver oil; the second patient's disease needs far greater stimulation, which indeed would aggravate greatly that of the woman; whereas in the case of the syphilitic patient neither of the methods about to be given for the former ones would be of any real service, but well directed anti-syphilitic measures will, in all probability, alone surely and completely remove the lesions.

This woman, then, with a tender skin, with hands cracked and painful, and yet itching greatly, requires, first, mild stimulation sufficient to relieve the itching; second, soothing applications to protect the cracked and denuded portions from the air, water, and dust; and third, internal remedies. To fulfil the first indications we will order the liquor picis alkalinus (℞ Picis liquidæ, ʒ ij.; potass. causticæ, ʒ i.; aquæ, ʒ v. M.) diluted six times with water. The affected parts are to be first gently bathed with this, then, as they improve, to be rubbed, with increasing force, first with linen, later with flannel, and this to be followed by an ointment (℞ Ung. picis, ʒ i.; zinci oxidi, ʒ i.; ung. aquæ ros., ℥ i. M.) which is to be kept applied as much of the time as possible. Internally she will be directed to take the following after each meal in a wineglass of water: ℞ Sol. Fowleri, ♏iij.; ferri ammon. cit., gr. ij; tinct. nuc. vom., ♏iv.; liquor potass., ♏vj.; tinct. cinchon. comp. ad ʒ i. M. It would be well if she could be induced to take cod-liver oil persistently for six months, even if the hands should be quite well before that time. Indeed, internal medication should always be continued for some period after the disap-

pearance of the disease, for it must be remembered that the local disease in such an instance depends largely on the general state, and if removed by local treatment is very apt to return from a continuance of the cause.

For the psoriasis of the palms, in the second patient, we will direct a good scrubbing, morning and night with ordinary soft potash soap, laying the back of the hand on a table, and using a piece of coarse flannel, and later even a scrubbing brush. The following ointment is to be kept closely applied at night: ℞ Ung. hydrarg. nitratis. ʒ ij.; ung. picis, ʒ ij.; ung. simplicis, ʒ iv. M. In view of its already long continuance it would be well to give him arsenic at the same time.

The man with the syphilitic palmar lesion will continue to receive mercury and iodide of potassium combined, in the usual formula, under which he is steadily improving. He has been obliged to stop the treatment several times from stomach irritation and other causes, which accounts in a measure for the rather tardy disappearance of the palmar lesion.

Progress of Medical Science.

Ergot and its Active Principles.—Dr. G. Levi has a long and instructive article in *Lo Sperimentale*, for August and September, 1875, in which he gives the results of his study of the physiological and therapeutical action of secale cornutum, especially in its application to obstetrics. He has endeavored to discover how its constituents act in individual cases. From all the facts collected, and from the investigations he has made, the following conclusions are derived:

1. The sum of the therapeutical effects derived from ergot are due to the presence in it of phosphoric acid.

2. The diseases for which ergot is a useful remedy receive equal benefit from phosphoric acid.

3. With ergot two distinct series of phenomena are reproduced by elements of different natures: the physiological (ergotism) recognize as a cause the vegetable principles (ergotine, erboline, etc.); the obstetrical, on the contrary, the phosphoric acid.

4. The hæmostatic effects, like the erbolic, are obtained equally, and with the same intensity and promptness, with phosphoric acid as with secale cornutum.

5. The quantity of soluble phosphoric acid found by analysis in recently pulverized ergot both in that which is old and in the hydro-alcoholic extract (ergotina), is proportional to the obstetric effects which are obtained from these various substances used separately.

Aconite and Aconitine.—M. Oulmont has been making exhaustive researches into the variations in the action of the different preparations of aconite, and the following are some of his conclusions: The alcoholic preparations of the fresh leaves, the stalks, and the seeds are almost inert in small doses, an ounce in animals and half an ounce in men producing no appreciable effects. The alcoholic preparations of the fresh roots, and the tinctures of the roots and the dried leaves, especially the two last, are more active; but they are uncertain preparations, and it is difficult to calculate their doses exactly. The officinal extract of the leaves is of little value. The extract of the roots, prepared from the aconite of the Vosges, is much more active, certain, and regular in its action, and is easy to administer, and consequently should be preferred. It can be given in doses of one-third to one-half a grain per diem, gradually increased to a grain and a half or two grains, without fear of accident.

Aconitine is very active, and great caution must be exercised in its administration. It should be given at first in doses of $\frac{1}{250}$ gr., gradually increased to $\frac{1}{60}$ gr. or even $\frac{1}{30}$ gr. He concludes with the statement that the roots contain most of the active principles, and these principles are contained in increasing quantities in the plants found in the gardens, in the Vosges, in Dauphiny, and in Switzerland. That of the Vosges should be preferred for the different preparations.—*Journal de Méd. et de Chir.*, January, 1876.

Rabies Successfully Treated by Woorara.—Offenberg, in his inaugural dissertation, Berlin, 1875, reports the case of a girl of twenty-four who had been bitten eighty days before by a dog supposed to be rabid. Injections of morphine and the inhalation of chloroform having been used without benefit, seven injections of woorara, amounting in all to three grains, were given in the course of five and a half hours. First the muscles became steadier, then the convulsive seizures less frequent, the dread of water and the photophobia disappeared, and the voice improved. Some symptoms of paralysis now appeared, which reached their maximum the following day. On the second day there was a slight relapse of the symptoms of rabies, which was checked by an injection of a little less than half a grain of the woorara. The patient recovered slowly, a certain degree of weakness and sluggishness, and especially weakness of sight, remaining at the end of two months. There was inflammation but no suppuration at the points of injection. —*Deutsche Ztschr. f. prak. Med.*, No. 52, 1875.—*Allg. Med. Cent. Zeit.*, Jan. 5, 1876.

Liquor Bismuthi for Hemorrhoids and Prolapsus Ani.—Dr. John Cleland freely admits, that in many instances hemorrhoids cannot be treated successfully without surgical operation, yet in a large number of cases operative interference is unsuitable. His attention was first called to the use of the liquor bismuthi, given as an enema, in a peculiar case of prolapse of the bowel. A middle-aged woman came for consultation, in such a condition that she could with difficulty walk, inasmuch as whenever she parted the thighs, at least one-half a yard of intestine was extruded. The whole surface of the mucous membrane exposed was of a deep raspberry red, in that chronic condition which some practitioners delight to treat with nitric acid. External supports and astringents had been tried, but had failed. The patient was then directed to mix a dessertspoonful of liquor bismuthi with half a wineglassful of starch, and after getting into bed, and returning the bowel to its place, to introduce this enema and retain it. A few weeks after, the patient returned, stating she was well. The treatment was ordered to be continued, and there was every reason to believe there was no return of the malady. In ordinary prolapsus in children, the same remedy has been used with invariable success. In hemorrhoids, where the mucous membrane is considerably involved, no application can compare with the injection of liquor bismuthi, it being painless; and as in the case of prolapsus, the improvement of the mucous membrane has a wonderful influence on both the veins and integument. In instances in which surgical interference seemed indubitable, by this treatment the patient recovered without the necessity of an operation.—*The Practitioner*, January, 1876.

THE SO-CALLED FUNGUS FOOT OF INDIA.—The cause of this strange disease, which occurs in some parts of India, especially in Madura (whence one of its names), has been attributed by Vandyke Carter to a fungus. Although the evidence was in favor of a fungus being the cause of the Madura foot, yet decided opinions of a contrary kind have not been wanting. Drs. Lewis and Cunningham, after years of study and examination of this disease, entirely negative the view that the disease has a fungoid origin. They have found indeed, in one variety, a fungus; but this appeared to be entirely secondary. They distinguish three varieties of the fungus foot, viz., the roe-like bodies, the pink particles, and the black masses. The first are shown to be fat in variously modified forms; the second are found to be pigmented concretions, not the slightest trace of a fungus or of other vegetable organisms being present in either; and the third are shown to consist of degenerated tissue, mixed to a greater or less extent with black pigment and fungoid elements. They deny that fungi or allied forms can act on healthy tissue, and really assert that disease of tissue always precedes their appearance, and is really the primary disease. They even appear to imply that fungi will only act on matter already dead, and that, therefore, living parts can never be infected by low organisms.—*The Lancet*, January 22, 1876.

DIAGNOSTIC VALUE OF THE ILIO-FEMORAL TRIANGLE, IN INJURIES OF THE HIP-JOINT.—Mr. Thomas Bryant attaches great value to this mode of diagnosis, particularly in cases of impacted fracture at the hip-joint. He confidently asserts, after repeated proofs, that while in a healthy subject the ilio femoral triangles are exactly similar upon the two sides of the body, with equal sides and equal angles, he can with equal confidence be assured that in all cases of injury to the hip, in which shortening of the neck of the thigh-bone exists, the amount of shortening can readily and accurately be made out, on comparing the bases of the triangles of the two sides. There are rare cases where obscure injuries to the hip-joint may not be cleared up by means of this test-line, but they are exceptional, whereas, by its use, a large number of cases that would have been called obscure have ceased to be so.—*The Lancet*, January 22, 1876.

DIPHTHERIA.—Dr. Robert Bell thinks that our conceptions with regard to the mode of ingress of the poison of diphtheria are far from correct. In its first stages it is purely a local disease, exactly as a chancre at its commencement is syphilis in the part only, not having yet affected the general system; or as vaccinia in its primary stage is purely local. If then the poisonous nature of the deposit in the mucous membrane of the mouth and throat can be destroyed, while the disease is yet local, we keep it in that condition and prevent its further effect on the health of the patient. Since Dr. Bell has adopted this method of treatment, he says he has lost only two cases from diphtheria, and these were cases which resisted, so that it was impossible to employ the treatment at all. He has treated a large number of cases, and with almost uniform success. From the very onset of the disease, he insists on free stimulation and plenty of nourishment. This dietetic treatment must be simultaneous, with local and general medical treatment; but the most important is the local application of substances which destroy the poisonous properties of the deposit on the throat. This application consists of carbolic acid, one part; sulphurous acid, three parts; solution of perchloride of iron and glycerine, of each four parts. The mouth should also be rinsed out frequently with a weak solution of Condy's fluid in water, and the following mixture taken in dessert-spoonful doses every two hours: R. Potassæ chloratis, ʒ iij.; acidi sulphurosi, ʒ iiiss.; tincturæ ferri perchloridi, ʒ iij.; glycerini, ℥ i.; aquæ, q. s. ad ℥ vj.—*British Medical Journal*, January 29, 1876.

THE RESULTS OF OPERATIONS ON SCROFULOUS PERSONS.—M. Bernard, in the course of his studies on scrofula in general, has arrived at the following conclusions on the subject. In the scrofulous the grave complications which succeed the traumatism are rare. The attacks of erysipelas or of lymphangitis are mild, when they occur at all, while diffuse cellulitis, gangrenous inflammation, and pyæmia are hardly ever met with. In general the scrofulous resist well the shock of an operation, so much so that Gerdy has been able to cite three amputations for white swelling in which the traumatic fever was almost nil. But it must be confessed that, although the scrofulous support the shock of an operation well, and rarely succumb during the first two or three weeks, the period of danger lasts much longer in them, and the final result is much more doubtful. In numerous cases the operation produces both local alleviation and an amelioration of the general symptoms, by removing a constant source of pain and exhaustion; but this temporary improvement, though raising hopes of a complete recovery, does not persist, and the patient soon after dies, worn out by the general disease. M. Verneuil expresses himself as follows on this subject: "Surgical intervention rarely arrests scrofula, aggravates it sometimes, but most frequently does not affect its evolution at all." M. Bernard speaks strongly of the value of alteratives, and especially of sea baths and country air.—*Le Bordeaux Médical*, January 25, 1876.

INTERMITTENT BRONCHO-PNEUMONIA.—In a paper read before the Academie de Médecine, on January 11, M. Bourgade, after some remarks on the changes in the paludal miasms in the provinces of central France, produced by sanitary measures, and the ameliorated hygienic condition of the population, stated that the typical intermittent fever has partly disappeared, to be replaced by an insidious form which impresses a peculiar stamp on all diseases and gives them an abnormal gravity. His paper treated particularly of the special characters assumed by broncho-pneumonia under the influence of the paludal miasm. This affection presents all the symptoms of the typical broncho-pneumonia, but with certain peculiarities that indicate a special pathogenic influence. For instance, the initial chill is repeated during several days, but does not indicate a periodical increase of the disease; or if the chill be wanting it is replaced by malaise, and a dull pain in the region of the spleen. Percussion reveals more or less extensive dulness, and measurement a remarkable enlargement of the thoracic cavity, due not to pleurisy, but to the congestive turgescence and disappearance of the lung noted by M. Woillez. The auscultatory signs are less marked than in the simple form of the disease, and vary in intensity with the appearance and disappearance of the febrile exacerbations. The pathognomonic character consists in fact in daily exacerbations of fever, which appear regularly night and morning, rarely in the evening, when, on the contrary, marked remissions are observed. The course of the temperature is not less remarkable. At the time of the access of fever it may rise to 104° or 106,¾°, then fall to 102½° or 100¾° F., and go on rising and falling with the exacerbations and remissions of the fever. The course

of the disease is irregular, and its duration often prolonged. It may last four or five weeks. It yields easily and rapidly to quinine, when given early, but if the miasmatic element be overlooked, the prognosis is grave. It may end fatally when neglected.

M. Bourgade believes this broncho-pneumonia to be, not an inflammatory disease, but an affection allied to intermittent fever. The irregularities in its symptoms, its advance by fits and starts, the regular daily exacerbations of the fever, and finally its ready submission to quinine, all point to its paludal origin. It is a special form of intermittent or remittent bronch.o-pneumonia.—*Gazette Hebdom.*, January 14, 1876.

Veratrum as an Antidote to Opium.—Dr. J. S. Todd, in a paper read before the Atlanta Academy of Medicine, advocates the use of veratrum as a substitute for belladonna in opium poisoning. He instances six cases in which this remedy was used, but does not attempt to explain its *modus operandi*. Four of these cases recovered entirely from the effects of poisonous doses of opium, veratrum being administered hypodermically. In one of these successful cases atropia did no good. Two of the six reported cases died, but in one the large amount of opium taken, and the length of time before the commencement of treatment, showed clearly to his mind that recovery was impossible. The good effects of the treatment were manifested by the length of time that intervened before death. In this case the patient received hypodermically, in less than six hours, a drachm of tincture of veratrum viride, without lowering the pulse; in fact, veratrum seemed rather to keep the heart going. In the other fatal case the patient, a boy of twelve years, was suffering from meningitis, and morphine had been given with after-symptoms characteristic of opium poisoning. Under the cold douche and three injections of three drops each of tincture of veratrum viride, the symptoms of opium poisoning disappeared, and though he died, it was from the force of the disease and not from opium poisoning.

While Dr. Todd feels every confidence in this drug as an antidote to opium, he advises not to neglect evacuating the contents of the stomach, the use of electricity and strong coffee, and recommends that the patient be walked, flagellated, tickled, etc.

Dr. Todd also firmly believes that the actions of o ium and veratrum are reciproeal, and that in verat rum poisoning opium is the remedy to be employed.

Differential Diagnosis between Serous Subperitoneal and Ovarian Cysts.—At a meeting of the Société de Médecine de Strasbourg Koeberlé read a paper on this subject, the diagnosis being based on the characters of the fluid contents. These cysts originate in the ovaries, uterus, Fallopian tubes, broad ligaments, and even in the kidneys; but, whatever the point of origin, their anatomical relations may be so similar as to render it impossible to determine to which variety they belong.

If the fluid obtained by puncture is thick, viscid, or fatty, and contains hair or epidermal cells, the cyst is ovarian; but when the fluid is clear and of low specific gravity, it is impossible without chemical analysis to say to what variety of cyst it belongs.

The fluid from the parovarian cysts, or those of the broad ligament, contains no albumen, is clear, slightly saline, and does not become cloudy when acids are added to it.

The ova ian cysts contain a fluid rich in albumen, and especially in paralbumen. (The precipitate obtained by nitric acid is redissolved in acetic acid.)

The tubal cysts, on the other hand, contain albumen and a little paralbumen. (Acetic acid increases the precipitate.) Exceptions to these rules exist, but they are very rare.

M. Koeberlé closed his communication with the following table, which includes the principal differentiai characteristics of these cysts:

Serous subperitoneal cysts.—Always unilocular. Contents very fluid, usually colorless and limpid as water, sometimes very saline; contain as a rule no albumen. Albuminous precipitate obtained with nitric acid, may be soluble in an excess of that acid.	*Ovarian cysts.*—Uni- or multilocular. Contents fluid, flowing more or less slowly, viscid, glutinous. Usually rich in albumen, metalbumen, paralbumen, giving with nitric acid a precipitate soluble in acetic acid.
	Contents more or less glutinous, sometimes entirely incoagulable by nitric acid and heat; in rare cases limpid as water, slightly frothy, containing only traces of albumen (Colloid cysts).
	Pure fat, fluid, mucus, masses of epidermis, hairs in suspension (Dermoid cysts).
	Examined under the microscope the fluid contains yellowish granular globules, characteristic of ovarian cysts, from three to thirty-five, or even sixty millimetres (?) in diameter. Their envelope is rendered more distinct by the addition of acetic or phosphoric acid. Usually emaciation more or less pronounced.
Embonpoint and generally a healthy look, even when the tumor is very large.	
Fluctuation usually well marked.	Fluctuations more or less distinct, sometimes limited (Multilocular cysts).
Walls thin.	Walls sometimes thin, sometimes more or less thick, firm, hard, bossed (Multilocular cysts).
	Ossification in parts (Dermoid cysts), sometimes the very hard parts are due to calcareous incrustations of the walls of the cysts.
Development slow, at times.	Development generally rapid, sometimes slow.
Attain, sometimes, a considerable size without becoming adherent to neighboring organs. Sometimes very adherent even when small.	Generally adherent from an early period, before their size is at all considerable.

—*Le Bordeaux Médical*, Jan. 11th, 1876.

The Indiana Medical College—Department of State University—held at Indianapolis its Seventh Annual Commencement, February 25th. The degree of Doctor in Medicine was conferred by Rev. Dr. Moss, President of the University, upon thirty-two graduates.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

PUBLISHED BY

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, March 18, 1876.

WHAT OUR MEDICAL SYSTEMS ARE, AND WHAT THEY MAY BE.

It is very pleasant and proper, in this our centennial year, to look back over the history of American medicine and American medical men, and mark with pride the advances that have been made in every department of our art. Perhaps we are apt to be too busy with the present and its needs to devote as much time to these matters as we ought, and while the names of our distinguished physicians and surgeons remain present in our minds, their achievements have often been forgotten. For this reason we owe a debt of special gratitude to our distinguished countryman, Dr. Clarke, for the laborious and scholarly task he has accomplished in setting before us the contributions Americans have made to medicine, and for the very interesting way in which he has presented his work.*

There are some points, however, in his article which touch upon the ever-vexed question of medical education, in which he seems to have given rise to misunderstanding in some quarters, if he has not laid himself open to criticism for the very favorable comparison which he draws between our system of teaching and those in vogue elsewhere. Living as the author does under the very shadows of an institution whose pre-eminence above the other medical schools in the country is a fact that few will be willing to deny, we can hardly believe that he regards the condition of our schools in general as satisfactory. In so far as he says that "our medical schools are an honorable contribution to the medical work of the century," we are quite willing to agree with him; when, however, he adds that "if the necessities and different conditions of Europe and America are impartially compared, we shall find that the American method of medical education yields as good a practical result to the nation as the European method of medical education does to Europe," then we confess ourselves sceptical—at least until the proofs are presented.

Dr. Clarke, however, takes care to tell us that "the schools, except in the case of Harvard, ... do not pretend to give a complete education, but only to supplement that which the student gets elsewhere." And then he says, speaking of the quality of the education, that "those who, like the apothecary of England and the Secundär Aerzt of Germany, are charged with the medical care of the mass of the community in Europe, are not better equipped for the practical work of their profession than their average American contemporary." We are unable, however, to see how any system of instruction can be satisfactory if it, except in the case of Harvard, does "not pretend to give a complete medical education." Nor can the comparison just quoted be regarded as flattering. Those who are conversant with the requirements abroad will hardly be pleased to have us informed that the mass of our doctors are fully up to the standard of "English apothecaries" or "Secundär Aerzte" on the Continent. The title of "general practitioner," which is conferred upon the graduates of the Apothecaries' Society, is certainly not an exalted one, and it is this, we take it, to which Dr. Clarke refers. It is one of the very easiest to obtain, and while it confers upon the possessor the privilege of practising, would, in the absence of a better degree, be a very poor certificate of his medical proficiency, if he desired to indulge in the higher order of metropolitan practice or was a candidate for a hospital appointment. A knowledge of surgery is not required for his title, and he need only attend three winter and two or three summer sessions, a remarkably short time in which to get an English degree. As for the class of continental sub-physicians to which Dr. Clarke refers, there are certainly many species differing according to the locality and existing conditions. If he refers to what are known in Prussia as the "Wundärzte," some sort of barber surgeons, their sphere is usually restricted, and if they are found overstepping its limits, they render themselves liable to the authorities in so doing, so that they are not to be regarded as filling the position of physicians in the sense of our ordinary practitioners. The same thing may be said of the French "officiers de santé;" they practise in certain defined departments, but in grave cases are compelled to call in the aid of a "docteur en médecine et chirurgie." But it is really mortifying to compare the requirements of even the best of our colleges with that of a really first-class degree, as for example a fellowship in the Royal College of Surgeons, or the title of Doctor in Prussia. To become an F.R.C.S. (and it is a very necessary thing to obtain if one would hold some of the higher positions in England) he must show evidences of having been suitably prepared for the study of medicine, must have studied six years, and have had a prescribed course of medical and surgical training in a hospital, and have success-

* "A Century of American Medicine," Am. Journal of the Med. Sci., Jan., 1876.

fully passed a rigorous examination. No one of our colleges exacts such severe conditions for a degree. And yet some of them hardly require half as much as is demanded even by the Apothecaries' Society. To obtain the title of Doctor in Prussia from the regular examining bodies requires satisfactory evidence of preliminary study, and a university education. The applicant must further pass satisfactory examinations in anatomy, physiology, chemistry, physics, and some one or other of the natural sciences, such as botany, as well as in surgery, ophthalmology, materia medica, obstetrics, diseases of women, and medical jurisprudence or hygiene. He must also have passed a prescribed time in attendance in the surgical and medical wards of hospitals, and have attended at least four confinements.

One of the most interesting and instructive books that have ever appeared on the matter of medical education is the one that Billroth * has lately written, and it will well repay careful study for any one who can read it in the original.

He tells us that there are in Germany, as we know there are here, two classes in the medical profession; one that would throw down the bars and make the acquisition of medical degrees an easy one, and another class that would insist upon stringent courses of study, making them more thorough and complete in proportion as general knowledge and culture advances. The arguments used are the same the world over. The one class says that the present requirements in Germany, and such as are urged upon our adoption by many in this country, are unnecessary. "Physicians have no need to be literati;" they need first of all to learn how to treat the sick; in fact the best educated men are often unsuccessful practitioners, while ill-educated men may have large and flourishing practices.

It is also urged that physicians are unfitted by high degrees of education and culture to practise among the lower orders, especially in the country places, for these people are better satisfied with those who are nearer them in their attainments, and can therefore sympathize better with them.

Besides, they say, the difficulties that are interposed between the student and his diploma will have the effect of frightening away many from the profession, and thus in time there will get to be an actual want of physicians. The expense of a full course of medicine is too great for the poorer students.

And finally they ask, Where is the money to come from if the system of instruction is going to continue to be so expensive?

Billroth answers many of these arguments so well that we insert in substance what he says:

In the first place medicine must either be progressive or retrogressive; it cannot stand still while other kindred branches of science are moving forward. It is by the study of the natural sciences especially that we are making progress; they, in fact, have given us the ophthalmoscope and taught us electrotherapy; while the application of the higher mathematics to the doctrines of light and sound have been very necessary in developing our present knowledge of the mechanism of sight and hearing. It is, in fact, the natural sciences which are now pushing us forward most rapidly in the diagnosis and treatment of disease. This is the very point Dr. Clarke makes when he tells us that the founders of modern physiology and pathology—John Hunter and Bichat—rescued medicine from empiricism by perceiving its relations to the natural sciences. And so it has been in this country, for though many an ill-educated man has had successful practice in the common sense of the term, those who, like Rush, Physick, Warren, and twenty others that we might mention, have not only been successful as practitioners merely, but have left an indelible impress on the medical history of their times, have been men of broad and liberal education, fully up to the scientific knowledge of the times, of which their contributions were the fair and legitimate offspring.

So far as its being undesirable that a physician should be a man of high education and culture, because he cannot then be on a par with his patients, the reverse is the case. The physician actually accomplishes more if he stands on a higher level, and in fact this is one that he has usually occupied even in the humble avocation of a village doctor; while he is most apt to be guide, philosopher, and friend to the lowliest of those he is called upon to treat.

As for the danger of frightening away students by the increased difficulties in obtaining a diploma we need have no concern; for notwithstanding the threatenings which have been made in Europe for some years back, Billroth tells us that the number of students has been rapidly increasing at the German universities, especially since 1867, and the same is true in this country, we have every reason to believe. In regard to the expense which long courses entails upon students, Billroth has the boldness to say in effect "then do not study medicine." The study of medicine of to-day is of such a nature that it is folly to think of embarking in it with the hope of being a successful practitioner without a very considerable outlay of money, so as not only to carry the student through the necessary curriculum, but well out into the first years of his practice. He inveighs against a class of students, which fortunately we do not see in this country—poor Jews from Hungary and Gallacia, who go to Vienna with the notion that they can acquire a degree by study, paying their way by working as telegraph boys, post-boys, selling matches, and the like; the fact being that they cannot earn money sufficient to buy the necessary books, or take the necessary courses, and therefore pursue medicine under

* Ueber das Lehren und Lernen der med. Wissenschaften. Wien, 1876.

the greatest disadvantage. They begin the practice of medicine only to be sorely disappointed by finding that they have no practice, and can get none that will yield them sufficient support, and therefore have to resort to some other means for their livelihood, at least for the first years of their practice, which should be spent by them in further perfecting themselves in the art. There is doubtless much truth in this which may be applicable to many students in our own country. The student of medicine requires imperatively so many adjuncts to his ordinary studies in the way of books and instruments, and should take so many special courses, that the expense, even in this country, is vastly greater than it used to be.

But if the question be asked where is the money to come from to sustain an elaborate system of education, we answer by *endowment*. If we satisfy the laity that medicine is a science as well as an art, and that it is actually developing itself by the discovery or application of new facts, in the same way as other branches of natural science, we shall at least command their sympathy, and may secure money for the proper establishment of such institutions as are now flourishing in Europe.

But there is another project which is now coming into notice, the aim of which is in the right direction, and promises most beneficial results. It is examinations of students by proper persons in each State, independent of the colleges. We cannot expect much benefit from legislation and legislators. They recognize the regular practising physician, the homœopath, and the eclectic as equal before the law, and perhaps nothing else can be expected. We can, however, do one thing—set our own house in order, and show the standard of attainment that we recognize as requisite for practitioners, and if the requirements be high enough, we shall soon have the credit for it. Make it creditable, and every young physician coming to practise in the State, and perhaps not a few in other States, will find it greatly to their advantage to have our State diploma. As it is with the F.R.C.S., so it can be with the diploma given under the auspices of our State Medical Society. Other medical bodies with a lower grade of requirements will soon be recognized as such by the public, and will soon hold a correspondingly lower position in public esteem.

There can be no great difficulty in organizing such a board from the members of the State Medical Society. As it will be more creditable for the medical colleges of the State to be in a minority, let the majority be non-college men. They then may meet and elect an examining board to serve for the year, sitting twice a year, at times agreed upon by themselves. Fixed rates of fees can be established in accordance with the time spent in examinations. Proper supervisors may also be appointed to attend at the examinations, and decide upon points of difference as they may arise. The diplomas thus issued may then be publicly given, as now, at the regular commencements of the colleges. Such a step as this would be the first one towards a uniform standard of requirement for graduation. If the standard were found to be too high for many who would otherwise be excellent practitioners, and the country were really in need of them, then it might be time for considering the question of a lower degree, as of M.B., or Bachelor of Medicine, much in the way that it is given at Cambridge or Oxford. We have, however, no desire to extol the cumbrous systems still existing in England, the stupid conditions that are enforced upon those who seek a license, and the endless array of titles, which, doubtless, are full of hidden meaning to the happy possessor, but of no earthly account to the great majority of his fellow-beings. What we do urge, however, is, that we do at least have one high standard for our M.D.'s which the holder may be proud to obtain and we to give. If our examining board should, however, find it advisable to grant a lesser degree, let it be distinctly known as such, and that the holder, whatever his title, is not an M.D., but a star of lesser magnitude.

MEDICAL ADVERTISING.

It is indeed a difficult and thankless task to plead for honesty in the face of the present determination of certain medical men in this city to ignore the obligations which they owe to the profession, and to dodge a strict compliance with the code of ethics which they have pledged themselves to support. But we still believe that there is enough of the right sort of feeling with the majority of our brethren to support us in our endeavors to correct a growing evil. Even at the expense of being considered radical on the subject, we have considered it to be our duty to oppose medical advertising in any shape, directly or indirectly, admitting of no compromise between what we believe to be right and what we believe to be wrong. Already we have been forced to say a great deal on this subject, but it seems that the end is not yet. Examples for criticism are being constantly thrust before us, which either compel us to notice them or give up in despair. The latest one of the sort is that of the Public Health Association, which we are pained to see offers a very convenient medium for public notoriety to some of its members.

We have no desire to question the motives of gentlemen who wish to educate the public on matters pertaining to health, but they owe it to their brethren to be extremely careful how they accomplish their object. In order to do this properly they should be above the suspicion of benefiting themselves individually in a purely professional way before the public. That they have failed in any such endeavor which they may have had is quite apparent from the proceedings of the last meeting. On that occasion the subject of diphtheria was before the Society- certainly a very interesting

one for the public. Instead, however, of presenting it in its proper light, and confining the discussion to preventive measures, an elaborate and strictly medical paper was read by one of the members, so full of technicalities that even the reporters of the daily papers could not understand its purport, and this was followed by the experiences of certain members in regard to its treatment. What is the natural effect of this upon the popular mind? Simply to prove that these gentlemen were the leaders of medical thought upon the subject, and were, if not the only ones who understood the disease, at least among the few who could be trusted in its management. There can be no excuse offered for misconceiving the object of the meeting. It was avowedly a public one, and the discussions were intended for a popular audience.

The meeting was openly advertised in the daily papers; the names of the gentlemen who were to take part in the proceedings were given in connection with the subject to be discussed, and the reporters of the daily press were invited to attend. As a natural consequence a report of the proceedings was given the following morning in the various city papers, and there was the usual mortification of seeing one's name in the public prints.

As the discussion of the subject is likely to be continued, opportunities will doubtless be offered to some of the other medical members of the Association for giving their extensive experiences in the treatment of this very interesting disease.

OVERCROWDING IN THE SCHOOLS.

The overcrowding in the primary departments in our public schools is in some degree due to the practice, among parents, of literally converting these institutions into mere nurseries for the smaller children. It seems, however, that the school authorities have no power to prevent this, and the children who are old enough to learn suffer in consequence. The President of the Board of Education recently remarked, that if he had his way he would allow no child under six years to attend school. He is evidently the right man in the right place.

Reports of Societies.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, March 2, 1876.

Dr. S. S. Purple, President, in the Chair.

Previous to the reading of the paper, Drs. J. E. M. Lordly, S. A. Raborg, Clinton Wagner, C. G. Stanley, A. B. De Luna, W. H. Katzenbach, Edward Bradley, and Matthew D. Mann were elected Fellows of the Academy.

The Librarian acknowledged the reception of an exceedingly valuable donation, made by Dr. Isaac E. Taylor, consisting largely of old and rare medical works, the more notable of which were the following: The works of Ambrose Paré, 1634; Anatomical Exercitations concerning the Generation of Living Creatures, by William Harvey, 1653; Complete Body of Chemistry, by Febare, 1670; Carswell's Illustrations of Pathological Anatomy, 1838; Bailles' plates, illustrative of pathological anatomy, 1799; Hebra's plates, illustrating diseases of the skin, 8 vols.; Bright's Reports of Medical Cases, with colored plates, 1827 to 1831, 3 vols.; Hooper's Morbid Anatomy of the Uterus, with plates, 1832; Albinus on the Bones of the Fœtus, with plates, 1687; Ricord's Complete Treatise upon Venereal Diseases, with colored plates; Cruveilhier's Pathological Anatomy, 1821, 2 vols.; Bateman's Delineation of Cutaneous Diseases, 1829; and 33 volumes of medical works, written by Boerhaave, Mead, Hoffman, Celsus, Miller, Paul Barbette, Haygarth, Otto, Rayer, Cheyne, etc., etc. The value of the donation was nearly $1,000. The reception of 100 periodicals from Dr. J. R. Leaming was also acknowledged.

Drs. Anderson and Adams introduced resolutions for the purpose of reorganizing the Sections on Chemistry and Public Health.

IS CRANIOTOMY, CEPHALOTOMY, OR CRANIOCLASM PREFERABLE TO CÆSAREAN SECTION IN PELVES OF 1¾ TO 2¼ INCHES? WITH A CASE OF LABOR IN A KYPHOTIC PELVIS OF 1⅞ INCHES.

Prof. Isaac E. Taylor read a paper upon the above question, which was the second part of the subject considered at a meeting of the Academy, held Sept. 15th, 1875.

Reference was first made to the mortality attending Cæsarean section, and from an examination of the statistics given by English, German, French, Belgian, Italian, and American operators, and also from Radford, the average was found to be 53 per cent. The figures of Dr. Harris were mentioned, in which only $26\frac{3}{10}$ per cent. of the cases terminated fatally, while something more than 80 per cent. of the children were saved.

Dr. Taylor recognized the fact that the success of this operation is materially influenced by delay, and is much more unfavorable when resorted to after the woman has become exhausted, than when performed before the strength has flagged to any great extent. With regard to craniotomy, cephalotripsy, etc., the success of the operation is influenced by the period at which it is performed, presence or absence of complications, condition of the mother, choice of instruments, correct principles of delivery through the different parts of the pelvis, etc., etc. Too great delay is culpable, and is the cause in very many cases of unfavorable results. Indeed, to delay is to contribute to bad results in all these formidable operations, for then we have to contend with exhaustion and a peculiar nervous condition which is of bad import.

Prof. Taylor then gave a detailed account of his case of labor in a kyphotic pelvis, contraction at the inferior strait, where there was no evidence of rachitis or malacosteon, and which measured 1⅞ inches. Delivery was accomplished with safety to the woman, the child weighing 11 pounds. The cephalotribe which Prof. Taylor employs is his own modification of the French instrument; the modification consists in its being made lighter, less curved, and more serrated.

In this connection the cases reported by Jones were studied with reference to their duration, when it was found that the average was 45 hours. The nature of the operation, said Prof. Taylor, is not to be blamed if it is too long delayed and improperly performed. Every

hour after rupture of the membranes entails danger to the mother. Dr. Taylor does not employ the cephalotribe or cranioclast as tractors, although more or less traction may be made with these instruments, but, as a rule, other instruments must come in to complete the delivery. The doctor has an aversion to the crotchet, and gives preference to the right-angled blunt hook. The cephalotribe and cranioclast are not *alone* sufficient to accomplish the operation, nor will the cephalotribe be superseded by the cranioclast.

Prof. Taylor then referred to cases in which he had effected delivery when the superior strait was contracted to 2 inches. In these cases he believes he has derived great advantage from turning the occiput to the posterior part of the pelvis; that is, the back of the child to the back of the mother. His operation by preference in these cases is version, and then perforation of the head, followed by such other instrumental procedure as the nature of the case may demand.

The advantage claimed for bringing the occiput posteriorly, was that perforation and the subsequent steps of the operation can be much easier performed from behind, than to be obliged to force a passage through the jaw for the purpose of emptying the cranial cavity. The method of performing version commonly resorted to by Prof. Taylor, is what is known as the two-finger method; that is, two fingers introduced through the cervix are aided by external manipulation.

"There is no reason," said the doctor, "why we should not resort to version in extreme cases, instead of allowing the patient to go on, for the woman can be delivered in a much shorter time than by the Cæsarean section, and with more safety." Version is the important item in the management of these cases, and is the peculiarity of Prof. Taylor's method.

In cases of labor where the pelvis is contracted to the extent under consideration, four methods of management have been given:

1. The ordinary method, craniotomy, cephalotripsy, cranioclasm, and traction by the cephalotribe and cranioclast.

2. Craniotomy, complete cephalotripsy, with destruction of the vault, making the head a face presentation, and to be delivered edgewise. Bary and Hull.

3. Craniotomy, partial or complete cephalotripsy, delivering the head sidewise by craniotomy forceps, a crotchet, or blunt-hook. Osborne.

4. Craniotomy, cephalotripsy with or without cranioclasm, and version performed directly after with the trial of the blunt-hook, or crotchet or forceps, whichever may be elected.

From the observations Prof. Taylor has made, he has arrived at the following conclusions:

1. That a mutilated child can be delivered with safety to the mother through a space of 1¾ in. anteroposterior, and 2½ or 3 in. transverse diameter, by craniotomy, cephalotripsy, or cranioclasm, when the vault has been destroyed, the face made to present edgewise, or the head sidewise.

2. That after cephalotripsy, or cranioclasm, if necessary, version with propulsion from above the pubes, early performed before the uterine forces are exhausted, is preferable to that just indicated.

3. That the cephalotribe or cranioclast cannot be considered as available tractors in cases of extreme contraction of the pelvis, but that other instruments become necessary to properly effect the delivery of the woman.

4. That the Cæsarean section should not be performed when contraction or deformity is present, as stated above, unless demanded by other conditions and complications.

Prof. Pallen remarked that the statistics concerning the mortality attending the operation of craniotomy, cephalotripsy, etc., were something horrifying; and while it may be true that the success can be materially improved by performing the operation at an earlier period in labor, yet he was of the opinion preference should be given to gastro-elytrotomy when the contraction of the pelvis is less than two inches. By resorting to this operation, the dangers attending Cæsarean section are avoided, such as hemorrhage, septicæmia, metritis, etc. Prof. Pallen was of the opinion that the statistics upon Cæsarean section are about as favorable as those found in connection with craniotomy, and certainly a large proportion of children are saved by the former operation.

He also regarded version as much safer in labor with a pelvis of three inches conjugate diameter than delivery with forceps. In the class of cases, however, mentioned by Prof. Taylor he favored the operation of gastro-elytrotomy as revived by Prof. T. G. Thomas, of this city, rather than resort to the use of cephalotribe or cranioclast.

NEW YORK MEDICAL JOURNAL ASSOCIATION.

Stated Meeting, February 25, 1876.

Dr. E. G. Loring, President, in the Chair.

REPORT UPON DISEASES OF THE THROAT.

The regular monthly report was made by Dr. Beverley Robinson, and embraced brief and concise references to a large number of subjects which have engaged attention during the year 1875. We can refer to a limited number only of the more important items.

Heitler has mentioned adenoid tissue in the mucous membrane of the larynx as a cause of catarrh and ulceration.

Dr. Bigelow, of Boston, has drawn attention to erectile tissue covering the inferior and middle turbinated bones, and it is claimed that the mucous membrane may, in consequence, be increased in thickness one-fourth of an inch.

Schroecker was quoted in favor of tubercular laryngitis being secondary to tuberculosis of the lungs.

Morbid condition of the bronchial glands in chronic whooping-cough was mentioned as a probable condition to account for the long duration of certain cases.

Auscultation of the œsophagus in front, for the upper portion and over the spine, or to the right, for the lower portion. Spasmodic dysphagia is unknown to the stethoscope.

Ozæna is almost always of a scrofulous or syphilitic nature

Politzer was quoted as speaking of vegetations in the pharynx, and reference made to the removal of the adenoid enlargements by excision.

Dr. Robinson expressed his disapproval of the operation for extirpation of the larynx under any circumstances.

The article in Ziemssen upon diphtheria, was quoted from, but Dr. Robinson objected to the use of vapor inhalations, for the reason that they are difficult in children, and in adults they are of doubtful efficacy. He believes that they aggravate rather than benefit, and should not be employed. Cubebs and other resinous substances were recommended. The doctor also entertains the belief that membranous laryngitis and diphtheria are identical.

A solution of sulphate of quinine, two grains to the ounce of an acidulated menstruum, was mentioned as a local application in cases of diphtheria and inflammatory sore throat, and had been attended by quite favorable results.

Dr. R. P. Lincoln remarked, with reference to the presence of adenoid tissue in the vault of the pharynx, that latterly he had employed chromic acid for the destruction of the enlarged follicles, in preference to nitrate of silver, or removing them with any cutting instrument; but that still later he had used the galvano-cautery for this purpose with the most satisfactory results. He has been able, by means of this cautery, to treat successfully, with two or three applications, cases which required a large number of applications of chromic acid, and the cautery is also much less painful.

Dr. Bennett exhibited instruments for spraying the nasal, pharyngeal, and laryngeal passages, and claimed for them that all parts of the nasal passages can in this way be reached.

A running discussion here ensued, in which Dr. Robinson maintained that it was an illusion to suppose the nasal passages could be reached in every part by a spray, especially in certain acute and chronic cases, in which there is a large amount of swelling of the mucous membrane, etc. He also objected to the use of spray in general in the treatment of this class of diseases.

Dr. Bennett maintained that in the cases to which reference had been made, there was usually no necessity for spray until the condition of the mucous membrane has been changed by constitutional treatment and other means. If necessary, however, the fine tubes can be pushed through between the swollen parts, and in some cases it might be demanded.

Dr. McIlvaine entered his protest against the doctrine of blood-poisoning. He maintained that the blood had received a complete chemical analysis, and then asked the question, Which element is affected in those diseases said to be due to blood-poisoning, such as diphtheria? He regarded the idea as a relic of the dark ages.

On motion, the Association adjourned.

Correspondence.

THE APPLICATION OF MEDICATED SPRAY TO THE GENITO-URINARY TRACT.

To the Editor of The Medical Record.

In The Medical Record of the 11th inst., Dr. Bradley calls attention to the value of atomized applications to the mucous membrane of the genito-urinary tract. He seems to urge this mode of treatment upon his professional brethren, and rather complains that although he called attention to it a year ago, it does not seem to have met with much favor.

Unless there is some unexplained mode of making the application, further than appears in his article in The Record, I apprehend that there are many whose preconceived notions of the anatomy of the parts referred to would prevent their even experimenting in this direction.

The instrument used in making the applications has a very familiar appearance, being apparently the common hand-ball atomizer, with what might fitly be termed a *modification* of the *tube* to adapt it to the conformation of the particular parts to be reached.

The illustration represents the spray as flying freely in all directions, and for some distance from the nozzle of the instrument, indicating that the spray, *as such*, impinges upon the membrane lining the parts referred to, viz.: the uterus, vagina, and bladder.

As Dr. Bradley proposes to give further details in some future article, will he kindly make clear one or two points that have arisen in the minds of some who have had no experience with this mode of application.

Are not the walls of the uterus, when not occupied by the products of conception—of the vagina in its ordinary state, and of the bladder when the urine is evacuated—so approximated as to leave no open cavity? Or, as Dr. Bradley gives us to understand, is the bladder when emptied of urine distended with air?

If, as many teach and many more believe, the walls of these hollow organs when not distended with their natural contents are in apposition, how much "spray" can be thrown upon every part of the viscus to be medicated?

If, therefore, what I think is the general belief respecting the condition and position of the parts referred to is true as a matter of fact, however beautiful the *theory* of the application of medicated "spray" to the genito-urinary tract, there seems to be a very obvious mechanical impediment in the way of its practical application.

When these old-fashioned notions are clearly shown to be wrong, and it is fairly demonstrated that "spray" is really applied to the parts designated, I see no good reason why medical men should longer hesitate to experiment with this method of treatment.

Benj. Edson, M.D.

140 Park Place, Brooklyn.

THE ELECTROLYTIC TREATMENT OF TUMORS.

To the Editor of The Medical Record.

Sir:—I have read, with much interest, Dr. Neftel's paper on "The Electrolytic Treatment of Malignant Tumors," in No. 278 of The Record, and sincerely hope that the "brief reply to the inquiries of some of the numerous readers," etc., is more satisfactory to others than to myself. We are told that "the most malignant tumors (cancers, etc.), at a certain stage of their development, can be radically cured by electrolysis, employed according to certain methods," but we are not informed what these *certain methods* are. The histories are related very imperfectly, where we are assured that the author effected cures in apparently hopeless cases. But he does not go into minutiæ, promising to do so in a separate monograph. Having owned for the past six years a part of this same work (I suppose), which was published separately, and the preface of which says the rest was then "preparing for publication," I fear that the American public may lose many valuable lives before its appearance.

On reference to Virchow's *Archiv*, vol. 57, 1873, we find that a paper had been published in vol. 48, 1869, reporting the case of Congressman T. T. D., and "the case gave rise to much misunderstanding, as I had published it very incompletely, proposing shortly to issue a very complete work on the subject."

In vol. 57 of Virchow's *Archiv*, the case of Mrs. H. (given in The Record, No. 278) is more fully reported, the *exact* line of treatment pursued being given. This may be either because our German brethren, being further advanced than ourselves, are better able to appreciate the improvements recounted, or because they will not so readily put up with half-finished journal articles.

Perhaps it might be as interesting to your other readers as it was to myself, to know what the "certain method" in this case was.

While Mrs. H. was under chloroform, three negative needles were introduced into the tumor, and a large positive electrode applied at some distance from the tumor; a current from 35 Siemens' elements was applied for 30 minutes. This was done April 19 and 28, May 2 and 6. From May 8 to June 10, the patient was treated daily with weak currents; a small plate-shaped negative electrode, covered with a moist cloth, being applied over the tumor, especially over the punctures of the electrolysis needles, and a similar positive electrode being applied at some distance for a time, then changed around. From six to ten elements were employed for fifteen to thirty minutes.

This account having been published in a German journal some three years since, and "reprinted in the leading journals of Germany, France, England, etc.," there certainly can be no impropriety in my quoting it here.

Yours, etc.,

C. E. H.

New Instruments.

AN IMPROVED FEVER THERMOMETER.

Messrs. F. G. Otto & Sons have contrived a self-registering thermometer, which promises to be of service to the practitioner. Its peculiarity of construction is such that there is no danger of losing the register by contact with the mercury in the bulb. This is such an annoying and oftentimes unaccountable accident, that any device calculated to make it impossible will be considered as a real improvement. It is proposed to prevent the descent of the register below a certain point in the tube, by means of a slight enlargement of the bore a short distance above the bulb. This is, so to speak, a supplementary reservoir, B, which is capable of holding the small pencil of mercury, and not allowing it to go farther, despite the most violent jarring. In addition to this, there is another contrivance which enables any person of ordinary skill to make a register for himself. Although this is obviously unnecessary in the instrument before us, it can serve as a very useful modification to the ordinary plain-bore tube. It consists of a globular excavation at the end of the tube, and continuous with the canal. Suppose the register is lost, that is, the small pencil of mercury has attached itself to the main column in the bulb. The tube is cautiously heated until the column of mercury is forced to the extremity and partly fills the excavation; a gentle tap with the finger detaches that part of the mercury already in the excavation, or cell, and the main column is allowed by the cooling of the tube to recede. Next the detached portion of mercury is shaken into the tube, or driven downwards by gentle heat, and the registering pencil is made.

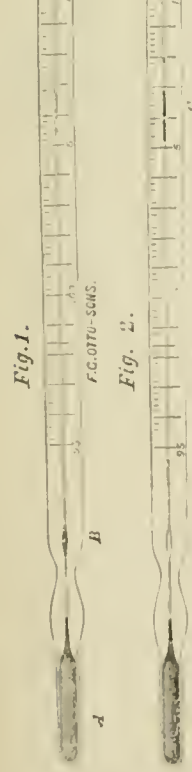

Fig. 1.

Fig. 2.

The cuts represent the register in the reservoir, and in the body of the tube respectively.

ARMY NEWS.

Official List of Changes of Stations and Duties of officers of the Medical Department, U. S. Army, from March 5th to March 11th, 1876.

Kimball, J. P., Assistant Surgeon.—Assigned to duty as Chief Medical Officer, with the troops in the field under command of Lieut.-Col. Geo. A. Custer, 7th Cavalry. S. O. 27, Department of Dakota, March 2d, 1876.

Medical Items and News.

Jefferson Medical College Alumni Association.—The annual commencement of the Jefferson Medical College took place March 11th. The degree of Doctor of Medicine was conferred upon one hundred and forty-six graduates. Professor William H. Pancoast delivered the valedictory address.

At the last annual meeting of this alumni association, Prof. Gross was elected President; Drs. W. C. Atlee, Elwood Wilson and J. M. Nolty, Vice-Presidents; Thomas H. Andrews and Richard J. Dunglison, Secretaries; and Prof. B. H. Rand, Treasurer.

Presbyterian Hospital.—The letter of resignation of Miss Woolsey, Resident Directress of Presbyterian Hospital, which has been under consideration by the managers of that Hospital for more than one year, was accepted at the last meeting of the Board, to take effect at the end of the year, in April. Dr. William T. White has been elected one of the attending surgeons.

Statue of Prof. Stokes, of Dublin.—The statue to Prof. Stokes, which has been placed in the Examination Hall of the Royal College of Surgeons, was unveiled on the 16th ult. He was president of the College in 1849. This is the third statue which has been erected in the hall, the others being those of Sir Dominic Corrigan and Sir Henry Marsh. A vacant corner is intended for that of Dr. Graves, the statue of whom is now in the hands of the sculptor.

Reduction of Salaries of the Health Board.—A bill is now before the State legislature for the reduction of the salaries of the city officials. It is proposed to reduce that of the President of the Health Board from $7,000 to $4,000 per annum, and that of the other commissioners from $6,000 to $3,000.

Army Medical Service in England.—There is a great deal of anxiety manifested concerning the proposed bill for the short service term. The measure is strenuously opposed by the profession and the medical press.

J. G. Adams, M.D., has been appointed Centennial Orator for the N. Y. Academy of Medicine.

Death of Andral.—Gabriel Andral, the eminent and venerated French physician, died on the 13th of February last, of bronchitis, at the age of 79 years. He was honorary Professor of the Faculty of Medicine in Paris, Member of the Institute, and of the Academy, and Commander of the Legion of Honor.

American Clinical Lectures.—Professor Roberts Bartholow, of Cincinnati, opens the second vol. of this series with an article on "The Principle of Physiological Antagonism as applied to the Treatment of the Febrile State."

Lectures on the Pathology and Treatment of Diseases of the Central Nervous System.—Dr. Eugene Dupuy will deliver at the College of Physicians a course of lectures on the Pathology and Treatment of the Diseases of the Central Nervous System, commencing March 21st, at 8 P. M., and continuing on every Tuesday and Thursday thereafter until completed. The course will comprise six lectures, fully illustrated by experiments, and will be free to the profession.

Analysis of Railroad Accidents.—In analyzing the many causes of accidents on railroads, a leading English authority has just stated, in a paper read before the Royal Institute, that human machinery was responsible for forty-one per cent. of these accidents, defective signals for twenty-eight per cent., defective roadway for eighteen per cent. and defective rolling stock for thirteen per cent. Taking a length of ten miles of railroad, for one passenger to be killed on this extent of travel, from causes beyond his control, he would have to travel some two hundred million eight hundred and ninety-six thousand miles before losing his life. If a person, then, was to travel ten hours a day, at a speed of thirty miles an hour for each of the 365 days in the year, he would probably be killed at the end of 1,835 years.

Medical Alumni Association of the University of Michigan.—The Medical Alumni of the University of Michigan organized last year, and the following officers new elected: President—R. C. Kendzie, Lansing; First Vice President—B. Barnum, Jackson; Second Vice-President—J. J. Mulheron, Detroit; Third Vice-President—I. E. Brown, Monroe; Fourth Vice-President—C. N. Metcalf, Eaton Rapids; Fifth Vice-President—W. J. Herdman, Zanesville, O; Secretary—W. F. Breakey, Ann Harbor; Treasurer—John Kapp, Ann Harbor.

The next meeting will be held the evening preceding the Commencement exercises. It is urgently requested that all who learn of the organization will promptly forward to the Secretary their own address and that of any Alumni they may know; also the names of any they may know to have died, with any interesting facts of their professional lives, and of the time and place and circumstances of their death. And that all who cannot meet with us will send some greeting to those who attend. Notice of the place and hour of the business meeting and of the supper will be given, and it is expected that a large number of Alumni will on this and each succeeding anniversary of their professional birth visit their Alma Mater and greet old friends.

American Medical Journalism.—The editor of the *Boston Medical and Surgical Journal* says:

"A glance at the list of our present periodical publications will show a peculiarity which is in marked contrast to those of other countries. Each separate medical community, however diminutive in proportions, is usually provided with a journal of its own. Most medical schools, particularly those whose qualifications for their work are of an uncertain character, consider an 'organ' a necessity. The result is a series of journals of purely local character, whose very names, in the majority of cases, are unknown beyond the moderate limits of their circulation. Our basis of classification may be considered rather geographical than scientific or literary. Indeed, the latter qualifications appear to be quite secondary to local interests. No sooner is the 'organ' fairly established than rival interests feel the need of protection, and an opposition journal springs into existence. The small stock of material which a busy community can muster can be divided between the two, and the gaps are filled with a large amount of borrowed plumage, while editorial space is devoted to a petty warfare, from which the cause of medicine receives but little benefit."

Pennsylvania State Board of Health.—An act has been passed by the Senate of Pennsylvania, and is now before the House of Representatives, for the creation of a State Board of Health, to consist of five physicians, to be appointed by the Governor. The duties required of them are *onerous*, and they are to receive *no salary*, but the actual personal expenses of any member while engaged in the duties of the Board shall be allowed and paid. Eight thousand dollars are appropriated for the purposes of this act and the expenditure properly incurred.

The editor of the *Medical News and Library* comments as follows: "The provisions of this act do not seem to us to be very promising of useful results. Gratuitous labor is rarely well performed, and to require services of physicians that would not be demanded of any other class of citizens is altogether unjust and unworthy of a rich State. It is also to be feared, that, as the appointment of the members of the Board rests with the Governor, political influence rather than merit will govern the choice."

Death of Dr. Z. W. Scriven, of Long Branch.—Dr. Scriven died suddenly on the 11th ult. One of his professional friends thus writes of him: "His sudden and unexpected demise has caused a gloom not only over this community, but to the hearts of the many of our transient visitors, who had learned to love him as a man and hold him in high regard for his devoted attention and professional ability. Possessing a vast fund of general knowledge, together with a generous, loving, and genial disposition, he had by an arduous practice of twenty-three years gained the confidence, commanded the respect, and endeared himself to the hearts of this community, and especially to the writer.—G."

Vital Statistics.—In the Bureau of Vital Statistics for the past week there were reported 679 deaths, against 651 for the week previous. The increased mortality was due chiefly to diphtheria, phthisis, bronchitis, and pneumonia. There was a decrease of six in the number of cases of small-pox.

The New York Dispensary has printed its 86th Annual Report, for 1875. During that year 42,162 patients were treated, and the aggregate number of persons treated since the foundation of the Dispensary is 1,659,950.

DR. S. S. PURPLE, PRESIDENT, in the Chair.

THE TREATMENT OF DIPHTHERIA.

THE object of the paper read upon the above subject by DR. C. E. BILLINGTON was, to contribute to the proof of the doctrine that the primary disease was a local affection and the source of constitutional manifestations. The doctor admitted that there were many cases which seemed difficult to explain upon this theory, but claimed that the exceptions were too few to weigh against that doctrine, which he couched under three heads:

1st. In the great majority of constitutional cases which have been under his observation, the local affections have been much more severe than in the other class of cases;

2d. The constitutional disease, as he had seen it, had been, not antecedent to, but consequent upon the local affection;

3d. The results of treatment on the principle of local disinfection strongly confirmed this view. The paper was based on observations made in 300 cases, of which 150 were under his own care; and the great majority of all the cases occurred in patients under 12 years of age.

Three elements entered into the study of the treatment of that affection:

1. Contagion; 2. Inflammation, and the formation of the pathological exudation and the accompanying nerve irritation, symptomatic fever, etc.; 3. The resulting specific and septic poisoning.

The indications in the treatment were, 1, to destroy the contagion; 2, to subdue the inflammation, which was most effectually done by removing its cause; and 3, to combat the absorption of the poisonous element from the spot at which the local disease was manifested.

Failing in these essentials, constitutional remedies were useless. In other words, local disinfection was the proper treatment for diphtheria. The physician should aim to destroy the poisonous exudation and fluids; but, at the same time, should exercise the utmost care, and not irritate the part affected.

That gave rise to two questions:

1. What were the best medicinal agents that could be employed for that purpose?

2. What was the best method of employing them?

The tincture of the chloride of iron was placed at the head of the list of remedies to be used as local disinfectants; and it also possessed other properties, which justly commended it as an agent to be employed in the treatment of diphtheria.

Lime-water, glycerine, chlorate of potash, carbolic and salicylic acid, and sulphite of soda were also mentioned in this connection.

With regard to the manner of employing these remedies for the purpose of obtaining their disinfectant influence, Dr. Billington recommended their internal use rather than topical application by means of a camel's-hair brush, sponges, etc. By that, however, he did not wish to exclude spray and the local use of remedies by means of the soft brush, for these means might be employed in certain cases with great benefit; but they should be used with the utmost care, lest a mechanical irritation should be produced. The following prescriptions were given:

℞ Tinct. ferri perchloridi..... ℥ iss.
Glycerini,
Aquæ, āā..... ℥ i.
M.

A teaspoonful to be given every two hours. For children under two years of age, one drachm of the iron was a sufficient quantity to enter into the prescription. When vomiting was a troublesome symptom, it sometimes became necessary to omit this mixture.

It was also recommended to administer teaspoonful doses of the following mixture, every two hours—that is, alternate with the above; but the administration should come after an interval of thirty minutes.

℞ Potassæ chloratis..... ℥ ss.
Glycerini..... ℥ iij.
Liquoris calcis, ad..... ℥ iij.
M.

The frequency of this dose was insisted upon by Dr. Billington as an item of very great importance.

It was also recommended to give teaspoonful doses of the following mixture, in addition to those already prescribed.

℞ Acidi salicylici.....grs. x to xv.
Sodæ sulphitis..... ℥ ss to grs. xlv.
Glycerini..... ℥ ss.
Aquæ, ad..... ℥ iij.
M.

It was recommended to use the following mixture in the form of spray for several minutes at a time, and just before the administration of each dose of medicine.

℞ Acidi carbolici.....m. x.
Liquoris calcis..... ℥ iv.
M

Applied by means of an ordinary perfuming atomizer. The doctor had found that children under two years of age so resisted the use of the atomizer that it was not available. He also recommended early resort to the nasal douché, and if offensiveness of the breath persisted, the nasal syringe should be resorted to and the salicylic mixture already mentioned.

For tough, unyielding membranes, the following was recommended.

℞ Tinct. of the chloride of iron....two parts.
Glycerini.....one part.
M.

Applied with a camel-hair pencil, but the greatest care should be exercised not to treat the affected parts roughly.

Dr. Billington regarded quinine as worse than useless, especially in young children, except as an agent to reduce the temperature. It was to be used for this purpose only when the temperature remained high after the initial stage had passed. For the high temperature, sometimes present early in the disease, a single dose of calomel was recommended. The doctor also maintained that the great majority of cases required no medication except the disinfectant measures, to which allusion had been made. Taking all the cases, probably 60 per cent. would recover spontaneously. Stimulants should not be used indiscriminately. The patients might have ice freely when they would take it; should be sustained by cold milk, perhaps eggs; and the juices of fruits, and the fruits themselves were regarded as beneficial.

Dr. Billington reported astonishing results, which he had obtained by following out this plan of treat-

ment. Membranous exudation was present in every one of the cases referred to in the paper.

Out of one hundred and twenty-four dispensary cases, there were ninety recoveries. Of these, one hundred and two were under his own care, and eighty-eight recovered. The largest number in a single month occurred in the month of August, 1875. In his private practice, the doctor had had seventeen cases, and all recovered, with but a single exception. Of these, seven were of the severe tendency; the others were mild. The average duration of the doctor's cases was from four to six days. These cases, added to those treated by Drs. Darkin and Bullard, in accordance with the same plan, raised the number to fifty-one, and with but a single death, already mentioned. The inhalation of steam was regarded unfavorably. Dr. Billington believed that he could prevent systemic infection, and also subsequent serious laryngeal complication, by early, thorough, and faithful resort to and continuance of the measures for local disinfection which he had recommended.

The paper was listened to with marked attention.

Dr. Barry, in discussing the paper, remarked that the success obtained by Dr. Billington in the treatment of diphtheria had been wonderful, and that he had not been able to obtain any such results by any plan of treatment he had ever adopted. Dr. Barry was of the opinion that diphtheria was strictly a constitutional disease, and the local manifestation was simply an indicator. His treatment, therefore, was local and general. He discarded the promiscuous use of irritating substances in the throat. Where the amount of exudation was small, he used tincture of iron or muriatic acid with glycerine; and if the patient was of sufficient age, an astringent gargle: alum, chlorate of potash, etc. If the patient was young, the vapor of hot water or vapor of iodine was recommended. In those cases in which the tonsils were pretty well covered, he had been accustomed to use a powder composed of sulphate of iron, chlorate of potash, and muriate of ammonia. This was blown through a quill into the throat every two hours.

His general treatment was supporting in its fullest sense, for the tendency to death was by asthenia. Iron with quinine, chlorate of potash, carbonate of ammonia, milk, beef essence, milk-punch, should be employed. The surroundings of the patient should be cheerful and pleasant; the unaffected children removed, if possible, from the house; the room continuously disinfected; and the sick quarantined. In his cases the ordinary duration had been about two weeks if the patient was to recover. The more acute symptoms passed away in from four to six days; and if the case were to prove fatal, it usually did so about the fifth or sixth day. He had not met with a single fatal case in an adult patient in his own practice.

Dr. Burke was also of the opinion that diphtheria was a constitutional disease with a local manifestation. He also regarded local applications by means of brushes and sponges as harmful. "The mild cases," said the doctor, "would get well of themselves, but perhaps they had better have given them a little cubebs mixed with mucilage." "The malignant cases," continued the doctor, "would die in spite of all treatment."

There was a class of patients between these extremes that could be saved, a certain portion of them, by the use of constitutional remedies, such as quinine, iron, etc. etc.

Dr. Burke mentioned the use of bromine with bromide of potassium, as recommended by Prof. Thomson; and in some cases it had evidently done good, but in many cases it had done no good whatever. He also recommended inhalation of the vapor of lime-water, especially where croupy symptoms became developed.

Dr. Hanks remarked that Dr. Billington's paper was exceedingly interesting to him, for two reasons: first, because of the remarkable success which had attended his mode of treatment; and second, because it was the expression in words of convictions which had been slowly but surely maturing in his own mind during the past fourteen years.

Dr. Billington's success was truly remarkable, for he well knew the type of the disease as it had appeared in the twenty-first ward; having had in his private practice, during the last five years, in that district, from twenty to thirty cases every year. He knew that many of these cases attended by Dr. Billington had been severe, and not a few malignant. Therefore, when the large per cent. of recoveries was considered, a cause must be looked for, and he believed two excellent reasons could be found for this satisfactory result. One was the kind of medicaments used locally and internally, and the other was the great care he bestowed in teaching the parents or nurses the *proper manner* of administering the remedies presented. This carrying out to the letter every little detail has had much to do, more than many had been led to suppose, in the cure of diphtheria.

He wished he could sufficiently emphasize the vast importance, in treating diphtheria, of careful attention to the minutiæ. Many had been, and still were in the habit of looking at the patient's throat, writing a prescription to be taken, ordering a gargle every few hours, and the nose to be syringed twice a day, believing that their directions would be followed. He knew, however, that one-half of the best class of patients even did not receive the full benefit of the medicaments through lack of proper, intelligent nursing.

He mentioned that the paper was interesting to him, because it was the concise and practical expression of views that had been maturing in his mind for several years. He remembered the disease as it appeared in New England fourteen years ago. Then it was not alone a disease of childhood, but adults were frequently attacked, and it seemed to him that nearly one-half the deaths were among those over fifteen years of age. The prize essay of Slade was the only authority for the treatment at that time. They were taught to cauterize the throat, and use severe remedies, etc., etc. He remembered how, while performing the part of nurse for his preceptor, he applied strong nitrate of silver, locally, twice a day, gave strong solution of tincture of iron and quinine, brandy and whiskey, and made external application of poultices of various kinds. About one-half of the patients died, both young and old. When he commenced practice in Massachusetts, the disease was prevalent in a malignant type, and he treated his patients as he had been taught. He could not conscientiously continue the use of strong caustics, and began to use tannin dissolved in glycerine. Also Huxham's tincture with aromatic sulph. acid, in frequent doses, internally, with a little pyrophosphate of iron occasionally. His success was better, and he learned thus that the disease did not require nitrate of silver in the first stage; and never, excepting in the necrotic or ulcerative stage, which appeared in some cases from the eighth to the fifteenth day. Within the last few years he had not changed the internal treatment, except that he had found more quinine necessary in New York than in Massachusetts. For local treatment, he had changed the glycerine and tannin for pleasant solutions of carbolic acid as a gargle, or

equal parts of powdered chlorate of potash and sugar thrown through a glass tube into the mouth and on the affected parts. He liked Dr. Billington's medicaments, and especially his preparation of carbolic acid and lime water, which he used with the admirable little atomizer.

The success of his treatment would not equal Dr. B's, yet he had been led to suppose that it compared favorably with most of his brother practitioners. During the year 1875 he had had twenty-seven cases, with twenty-one recoveries and six deaths. As one of the latter number occurred out of the city, and he saw the patient for the first time after it was too late to do any good, he deducted it in making his per cent., and therefore reckoned this 70+ per cent. of recoveries as a fair record, considering the type of the disease. There was one practical suggestion on which he laid greater stress than had Dr. Billington. He believed he had met with marked success in enforcing a sort of quarantine regulation when the disease had appeared. A careful and thorough disinfection of the room and apartments of the patient and family could not be too strenuously insisted upon. For this purpose he used sulpho-carbolate of lime. He also compelled a persistent administration of the antiseptic remedies, carbolic acid in solution, or pulverized chlorate of potash, to all the unaffected members of the family. In carrying out that régime during the past year, he had had the satisfactory result of preventing the spread of the disease to other members of the family. In several instances where there were four or five small children that result had been attained. In conclusion, he wished to say that we could not be too careful, using all the means our knowledge could command, in preventing the ravages and spread of that fearful disease.

Dr. E. G. Loring, President, in the Chair.

PERI-NEPHRITIC ABSCESS IN CHILDREN.

Dr. V. P. Gibney read an interesting paper upon the above subject, in which he reported and analyzed the histories of nine cases. Of these, seven terminated in abscess with external opening, and two in resolution. The existence of that affection had been denied by some authors; and, excluding all cases in which the abscess had been clearly of a secondary character, only three cases had heretofore been placed upon record. The ages of the patients, in the cases reported by Dr. Gibney, were respectively, 8, 1½, 6, 9, 3½, 2½, 6, 10, and 2 years. Six were females, and three males. In seven cases no exciting cause could be found. Six out of the nine gave no evidence of struma. In seven cases the abscess (including the three cases reported by others) were upon the right, and in five upon the left side.

SYMPTOMS.

The disease usually began with a rigor, followed by febrile symptoms, more or less severe, loss of appetite, general indisposition, lancinating pains, and the locality of the pain was perhaps not positively determined.

Constipation was always present. There was elevation of the shoulders, a disposition to stand with the body leaning forward, flexion of the thigh, pain in the region of the kidney, tenderness upon pressure, prone position, tumefaction, and, finally, fluctuation. These symptoms, associated with the fact that the attack was an acute one, were regarded as those chiefly to be relied upon in making a diagnosis. Dr. Gibney regarded diagnosis of peri-nephritic abscess in the very young child as impossible. The most prominent portion of the abscess in these cases was situated near the centre of the crest of the ilium, some three or four inches to the right of the vertebral spinous processes. In one case the tumefaction in the right lumbar region was five inches in longitudinal, and eight inches in transverse measurement. In this case jaundice was present. Spasm of the psoas muscle was regarded as a notable symptom, and in the cases reported was relieved in a marked degree after the evacuation of the pus. The practical diagnosis of this affection from hip-disease was not always easy.

While studying some of his cases, Dr Gibney had felt almost prepared to admit the impossibility of making a differential diagnosis between peri-nephritic abscess and caries of the vertebræ. But when a case came under observation in which were present rigors, fever, nausea and vomiting, constipation, loss of appetite, pain in the side, etc., and the attack acute, spinal disease was believed to be very easily excluded. In primary uncomplicated cases the prognosis was favorable, and the treatment consisted in attention to the general condition of the patient; and, as soon as fluctuation became distinct, evacuating the contents of the abscess, either by means of the aspirator or bistoury. Dr. Gibney remarked that he had not derived any special advantage from injecting the cavity of the abscess after the pus had been evacuated.

Dr. Gibney's paper can be found in full in the *Journal of Obstetrics*.

Stated Meeting, March 10*th*, 1876.

Dr. F. P. Foster, Vice-President, in the Chair.

THE PROPER CONSTRUCTION OF GALVANO-CAUTERY APPARATUS.

Dr. H. G. Piffard read an interesting paper upon the above subject, in which he referred to the fact that the treatment of disease by means of the galvano-cautery had been restricted, because of certain inconveniences, such as size of instruments, non-portability, the presence of noisome fumes, etc., etc. These obstacles, however, had been almost entirely removed by instruments latterly devised, the more notable of which were the battery of Dr. Byrne, of Brooklyn, and that of Dr. Dawson, of this city.

Dr. Piffard inclined to give Dr. Dawson's apparatus the preference; consequently, the interest of his paper centred upon the question, Was it possible to construct an apparatus still more powerful (than Dawson's), without increase in size? To this question the doctor gave an affirmative answer, and proceeded to speak of the qualities which a desirable battery should possess. These were the following: It should be in the highest degree portable, reliable, durable, convenient and compact, as far as these essentials could be made compatible with each other. The problem, then, was to combine these elements in such a manner as to give the greatest possible efficiency to the apparatus. Here Dr. Piffard entered into a detailed description of the various portions of the apparatus, the battery, the electrodes, the fluid, the poles, and cord, etc. Dr. Piffard then exhibited a battery constructed in accordance with the principles detailed, and which corresponded with the Dawson battery in all its essentials, except the agitator. To summarize: In Dr. Piffard's, and also in Dr.

Dawson's battery.—for these were the two placed in competition,—platinum was employed as the negative plate; the measurements adopted by Dr. Piffard were nearly the same as those employed by Dr. Dawson; the number of wires (pure copper) in Piffard's conducting cord 500, in Dawson's 125; and Dr. Piffard employed the air agitator, while Dr. Dawson used an agitator which he had patented.

The special points of superiority which Dr. Piffard claimed for his battery were, a larger surface of platinum, hence more electricity, without increasing the size of the apparatus, and the air agitator.

His battery had four negative plates; *i.e.*, two platinum plates, and three zincs in each cell. Dr. Dawson's battery had two negative plates; *i.e.*, one platinum plate and four zincs in each cell, and his conductors contained 125 wires. The platinum plates in Dr. Dawson's battery were somewhat larger than those in Dr. Piffard's.

The strength of the fluid used in each apparatus was the same, but the quantity required by Dr. Piffard's battery was somewhat less than that required by Dr. Dawson's apparatus. The two machines were then brought out for trial, and the same wire, somewhat larger than the commercial, used by each operator.

Dr. Dawson was able to heat it without using the agitator, so that one could simply smell woollen when the two were brought in contact; but with the agitator it was quickly brought to a bright-red heat, which remained for some time.

Dr. Piffard was able to heat the same wire visibly red without using the agitator, and with the agitator close to a white heat, which also remained for some time.

"But," said Dr. Dawson, "why not?—for Dr. Piffard's battery had double the negative surface."

Dr. Piffard remarked that it proved that what he had aimed at had been accomplished.

Dr. Dawson maintained that a battery stronger than his own was unnecessary for purposes of galvano-cauterization.

Dr. Dawson exhibited a battery which Dr. Piffard acknowledged was more powerful than the one he had devised, but at the same time claimed that it was not the instrument against which he had made his competition, for it was not the apparatus which Dr. Dawson had placed upon the market.

Dr. Dawson admitted that it was not the instrument upon the market bearing his name; and furthermore, he recommended that it should not be used for galvano cautery purposes, because it was altogether too powerful, and would destroy the platinum knives too freely.

As the batteries were operated, it was a fair conclusion that the effect produced by Dr. Dawson's agitator was quicker and more durable than that produced by the air agitator employed by Dr. Piffard. It was also quite evident that the air agitator was not in good working order. Dr. Piffard also recommended a single connecting-piece into which all the knives can be fitted. This he regarded as a convenience, for the operator was then able, by means of a pair of pliers, to construct an impromptu instrument from a piece of platinum wire. Some device in the handle for breaking the current, the button-break and others then exhibited, were regarded as essential, for it placed the degree of heat under the immediate control of the operator. The use of blue eye-glasses was regarded by Dr. Piffard as a valuable accessory in some cases, as they protected the eyes of the operator from the dazzle of the heated wires or knives, and enabled him to be more exact in making certain delicate applications.

The discussion was quite sparkling, and at times rather electrifying.

Stated Meeting, March 17th, 1876.

Dr. E. G. Loring, President, in the Chair.

GENITAL IRRITATION AS A CAUSE OF NERVOUS DISEASE.

Dr. A. McLane Hamilton read an interesting paper, in which were embodied the results of observations he had been led to make on account of the frequent occurrence of nervous disease depending upon irritation of the external organs of generation. Dr. Hamilton considered these cases under two heads:

1. Those depending upon reflex irritation, independent of sexual excitement, although the latter might enter as a complication; and
2. Those in which erethism acted as a cause of central disease. This erethism might be continuous or frequently repeated.

The doctor was of the opinion that these causes had much to do with the functional nervous disturbances met with in infancy and childhood, and that these cases were not to be thrown upon the medical scapegoat, dentition, intestinal irritation depending upon worms, etc. But, while recognizing the fact that a new channel for observation had been opened which might lead to a more intelligent explanation of many disorders incident to infancy and childhood, "yet," Dr. Hamilton felt compelled to believe that, with regard to the external organs of generation in the adult, the field was more restricted, especially in the male subject. At this point the doctor proceeded to study the complex character of the nerves which supplied the genito-urinary apparatus, and also the relation which this bore secondarily to the cerebro-spinal axis. In this anatomical study, the fibres of the sympathetic and the cerebro-spinal systems were found to be intimately associated; and this intimacy was manifested in the external organs of generation in both sexes, as seen in the glans penis, clitoris, etc. etc. Arndt was quoted as authority for the statement that the paccinian corpuscles found in the glans penis and clitoris were in some manner connected with the vaso-motor fibres.

Attention was next drawn to the physiological action of the nerves supplying those parts; and from that part of the study, together with the anatomy, the fact had been derived that erection of the penis and clitoris was due to paresis of vaso-motor nerve fibres. That being the case, they ceased to stimulate the vascular walls, dilatation of the blood-vessels occurred, the organ became distended with blood, and an erection was displayed.

Reflex sensations from those parts produced a variety of phenomena, both motor and sensory, which depended upon impressions conveyed to the brain and spinal cord. These phenomena might also be developed by peculiar psychical states.

The general influence which excitement of the external organs of generation had upon the nervous system could be seen by studying the physiological condition, known as orgasm. It was not difficult, now, to understand how pathological conditions might be developed by any disturbance of the normal condition of that anatomical and physiological arrangement.

Carrying the physiological study a little further, the part played by other ganglia and nerves than those immediately connected with the generative apparatus was reached, and psychical, sensory, and motor manifestations found, which showed that the cerebro-spinal system in general was affected. The vaso-motor influence attending an erection might be from remote centres,

as many of these filaments distributed to the penis had their origin in the vaso-motor centre of the medulla. Now, the original sensory impression might be conveyed directly to an inhibitory centre of the cord, and give rise to changes in its vascularity through the medium of the vaso-motor fibres; or the original disturbance of the vaso-motor filaments might be in the organs themselves.

Again, a sensient impression might go directly to the medulla and produce a secondary change in the centres there, chiefly in the way of ischæmia.

Dr. Hamilton then proceeded to the statement of certain other physiological facts which had a direct connection with the pathology of the conditions under consideration. The first was, that gross stimulation, passing from the periphery of a nerve, did not always go to a definite nerve centre, but generally went to a number.

Oft-repeated special impressions would make a new channel for themselves; and a particular variety of irritation might be reflected so frequently upon one spot that the function of the locality would be impaired. We might have, for instance, sensory impressions, certain forms of contraction, and mental disturbances in three different cases as the result of certain external impressions.

Turning attention to the pathological field, there were three things which should engage attention: 1. Sensory impressions at the periphery; 2. Their transmission; 3. The results. Under the first head, the irritation might be painful or purely agreeable, but both were liable to be conveyed to the nerve centres and do harm. Why these forms of irritation should be received and transmitted in a different manner, and why these special nerves received a peculiarly distinct sensation, remained to be explained. The prick of a pin never produced the same result obtained by friction. There was nearly always motor response resulting from the latter morbid impression; which manifested itself either by convulsions of both lower limbs, with a disposition to flexion of the legs and thighs, and marked adduction of the toes; or there might be general movements of both upper and lower limbs. There might be epileptiform convulsions, and there was frequently mental disturbance, varying from simple irritability to confirmed dementia. In this connection, the doctor expressed the doubt that there were any cases of mental trouble, associated with genital irritation, where masturbation, either unconscious or wilful, had not been practised.

Attention was next directed to the various dysæsthesia mentioned by the patients of hysterical tendency, such as coldness and moisture of the glans, or peculiar burning sensations, etc. There was really no such condition, for the temperature of the parts was normal. Patients who made these complaints were nearly always masturbators or suffered from spermatorrhœa. It was also important that the physician should determine whether the condition of the genital organs was primary or secondary; and that led to the consideration of such diseases as myelitis, etc., etc., and their attendant symptoms. With regard to change in physiological functions that might follow a formidable reflex irritation, Dr. Hamilton took issue with Brown-Séquard as follows: Brown-Séquard held that there was first, contraction of the blood-vessels; and second, that there were no nutritive changes. In reply to these, Dr. Hamilton suggested that prolonged spasm or contraction must give way to an opposite condition; and, therefore, hyperæmia instead of anæmia was present. This was the view entertained by Anstie. Dr. Hamilton also believed that secondary nutritive changes were very probable results.

The prominent nervous symptoms which attended continued morbid peripheral irritation sent from the genitals either to the bladder, spinal cord, or medulla were divided as follows: 1. Those expressed by want of muscular power, such as paresis, including paraplegia and partial paralysis of isolated groups of muscles, and the muscular fibres of the bladder. 2. Sensory, such as hyperæsthesia, anæsthesia, and dysæsthesia. 3. Vaso-motor, such as local hyperæmia and priapism. 4. Hyperkinesis, including choreaic movements and transitory contractions. 5. Psychical disturbances, such as loss of consciousness, impairment of memory, irritability, melancholia and dementia. The patient might present many of these symptoms at the same time. In children, various congenital defects and acquired bad habits had preceded the appearance of some of these symptoms; and in adult life they were developed in consequence of venereal excess, which was common, and, more rarely, by stricture and other urethral difficulties. The above acted by inhibitory reflection; and, beside these, there were certain idiopathic and traumatic neuroses of the penis. In the cases which had been reported with morbid conditions of the organs under consideration, attention was directed to phimosis or other genital irritation, and stricture of the urethra. Dr. Hamilton then gave a brief analysis of the ten cases reported by Dr. Sayre, and added the histories of four which had fallen under his own observation. From these cases the following conclusions were drawn:

1. That convulsive movements, more particularly of the lower extremities, the spastic contractions of the flexors of the thighs and legs, were connected in some children with a continued irritability of either the glans penis or the clitoris.

2. That, as a rule, beyond irritability, there were no mental symptoms.

3. That exaggerated power, or hyperkinesis, was the rule.

4. That atrophy or actual paresis were exceptional.

Dr. Hamilton next turned his attention to these nervous conditions depending upon another form of irritation, namely, that associated with sexual excitement. That venereal excesses and masturbation were causes of nervous disease, in the greater number of instances, there could be no doubt. Clinical experience attested that statement. The disease might be a neuralgia, epilepsy, and even insanity. Insanity depending on that cause was thought to be less common among adults than among children. Reference was then made to nervous symptoms depending upon

STRICTURE OF THE URETHRA,

and the opinion expressed that that rarely produced other than local trouble. To his support he brought Drs. Keyes and Sturgis of this city, while Drs. Gouley and Otis held to opposite views. With reference to the cases reported by Dr. Otis, Dr. H. remarked that any long-continued irritation at any peripheral part of the body, particularly where the nerve supply was abundant, might produce serious neuric symptoms. There could be no manner of doubt but that those troubles were not as constant and common as Dr. Otis suggested, was, to his mind, not at all certain. The doctor also disagreed with Dr. Otis as regards the normal calibre of the meatus and urethra; and regarded extreme dilatation, sudden and severe, as very liable to be followed by bad results. It might be assumed, however, that when the meatus was closed after ulceration, or failed to admit a moderately large sound, it should be enlarged. So too with the urethra; very large sounds did more harm than good. Dr. H. was of the opinion that vastly too much importance was attached to irritation of the geni-

tals as a factor in nervous disease; and, while recognizing the important part it might, and often did, play in the production of such derangements, he believed that some were inclined too frequently to remove the foreskin or dilate the urethra, when in one case the covering of the glans was a normal condition, and in the other the canal was large enough to permit the performance of the functions designed by nature.

The paper was discussed by Drs. Gibney, Post, Stein, Ludlum, and Sell.

Progress of Medical Science.

Rheumatism and Traumatism.— M. Verneuil recently communicated to the *Académie de Médecine* some interesting observations on the relations of rheumatism to traumatism, prefacing them, however, with the remark that they were still too few and too incomplete for synthesis. He divided all cases of wounds or operations on rheumatics into three classes: 1st, those in which the injury followed its normal evolution; 2d, those in which the diathesis seemed to manifest itself at the point of injury; 3d, those in which the injury excited rheumatic manifestations. The first class was by far the most numerous, the rheumatism ordinarily creating no special action on the seat of injury, and not modifying the process of cicatrization. In certain cases, however, the diathesis manifested its influence by serous effusions, œdemas, and simple or hemorrhagic congestions of the pseudo-phlegmons, accompanied by intense pains; in a word, by all the signs which characterize the arthritic conditions of wounds. In concluding, M. Verneuil maintained that the facts adduced proved: 1st, that traumatism can awaken a latent rheumatismal diathesis, and extend its manifestations to organs previously respected; 2d, that the most various forms of injury possess this exciting power; 3d, that the diathetic manifestations excited by it are of very different kinds (articular inflammations, cutaneous eruptions, neuralgic pains, pericarditis, etc.). How this exciting power acts in awakening a diathesis; why, once aroused, its manifestations affect one organ rather than another; and why the seat of injury is only occasionally affected, are questions still *sub judice*.—*Gazette Hebdom.*, Jan. 14, 1876.

The Formation of Sugar in Animals.—The following extracts from a paper read by M. Cl. Bernard, before the *Académie des Sciences*, are interesting, as epitomizing the labors and discoveries of the great physiologist on the glycogenic function of the liver.

I. "The blood of man and of animals is invariably saccharine. I have shown that the constant glycæmia depends on a normal function of the liver. About the same time I showed, by other experiments, that this physiological production of sugar in the liver is dependent on the influence of the nervous system, and that after injuring a particular spot in the fourth ventricle, not far from the origin of the pneumogastries, the saccharine matter is poured into the blood in such quantity as to render the animal diabetic. It was the ensemble of these facts that led me to admit the existence of a function of the hepatic organ, until then unknown, which I named the *glycogenic function of the liver*. . . . Next I found sugar in the allantoid and amniotic fluids, and in the urine, showing that diabetes is in some measure the normal condition in the fœtus. I obtained, moreover, especially from the muscles and the lungs, a substance that can produce sugar by a sort of special fermentation. I added, finally, some experiments on the influence of saccharine matter on the development of organic cells. From that time glycogenesis seemed to me to be, both in animals and in vegetables, a general physiological phenomenon, accompanying everywhere the manifestations of life. . . .

II. "But it was not sufficient to have ascertained the formation of sugar in the liver, it was necessary to penetrate deeper into the phenomenon, and to endeavor to make out its mechanism; this I called the second period of the question. It was marked by the *experiment of the washed liver*, and the discovery of the glycogenic matter, a discovery that in a manner changed the aspect of the problem by uniting it to one of the most difficult questions of General Physiology, that of the intimate nutrition of the tissues. . . . I have demonstrated that, in place of seeking the substance which precedes and produces the sugar immediately in the blood, it was necessary to locate it in the liver itself. . . .

"I finished by being convinced that the liver continued its glycogenic function after its removal from the body, and that after a certain time the quantity of sugar increased really and rapidly, after which time the quantity remained almost fixed. This was an unforeseen but most instructive fact. It demonstrates clearly the instability of the vital properties, and at the same time makes us appreciate the delicacy and all the difficulties of chemical analysis applied to the fluids and tissues of the organism. The same organic tissue, analyzed in exactly the same way, at intervals of five, ten, or fifteen minutes, is no longer the same tissue and does not give similar analyses. This applies not alone to the hepatic tissue—it is a general quality. All the animal fluids and tissues, within as well as without the organism, present a rapid and incessant chemical change.—*Gazette Hebdom.*, Jan. 21, 1876.

Thrombosis of the Cavernous Sinuses.—At the annual meeting of the Clinical Society of London, Dr. Dowse reported a case of a patient, robust and well built, who had received a blow on the occiput by being tripped up. He was slightly stunned, but able to walk home. No cerebral symptoms followed till the third day, when severe headache set in. The attacks of headache were varied by seizures of faintness and shivering, and he complained of the perversion of taste. The day before he came under Dr. Dowse's care, his vision became cloudy, and in a few hours was totally lost. The other special senses were good; cranial and spinal nerves normal; pupils dilated; the optic discs were swollen, and patches of retinal hemorrhage were discovered, the veins being large and tortuous. Death supervened upon an attack of erysipelas of the scalp, and the day before death, there were paraplegia and coma, but no convulsions or rigidity. No fracture of the skull was detected after death, but both cavernous sinuses were found completely occluded by fibrous clot. There was a recent hemorrhage into the right anterior cerebral lobe, which contained a clot, surrounded by punctiform hemorrhages. At the base of the brain there was a protrusion of cerebral substance, apparently due to the pressure of the clot. Dr. Dowse thought that thrombosis of the cerebral sinuses was more frequent than was supposed. Hemorrhage into the anterior lobe was rare. In the after-discussion, Mr. Hulke wished to know whether there was a pulsation of the orbital tissues, closely simulating aneurism, a symptom which was often described in cases of thrombosis of the cavernous sinus. He had himself seen it, and thought it explained by the diastole of the ophthalmic artery, being accompanied by

tension of the fluids in the tissues of the orbit. Mr. Holmes remarked that in many of these cases a loud murmur could be heard with the stethoscope. Dr. Dowse said that these signs were absent in his case. No stethoscopic examination of the head was made. Mr. Hulke, in reply to the President, Sir William Jenner, as to the nature and seat of the murmur, said that it was rhythmical with the pulse, and was attributed to compression of the carotid artery in the sinus, probably intensified by its conduction through the bones of the skull.—*The Lancet*, January 22, 1876.

Invasion of the Lymphatics of the Lung by Pleurisy.—At a meeting of the Pathological Society of London, Dr. Moxon presented a specimen of this kind, taken from a man, twenty-nine years of age, who was seen shortly before his fatal illness in good health. Three days later he was found in a sinking condition, half unconscious, with pulse 160, respiration 60, and hiccough, and died suddenly. At the post-mortem, ten hours after, the body was found already decomposing; the blood was of a dark color, staining the tissues, and the peculiar odor found in blood-poisoning was present. The only morbid condition discovered was that there were three ounces of sanguineous pus in the right pleura. Further examination showed the network of the lymphatics of the lungs to be filled with pus, which oozed from them on section, this condition extending as far as the bronchial glands. The lymphatics of the pleura were unaffected. At the posterior surface of the right bronchus there were two patches of coal-black color, and the bronchial glands behind this were much diseased. Two years ago two similar cases had been exhibited, in which intense pleurisy had invaded the lymphatics of the lung, and in both these cases there was obstruction of the bronchial glands. Dr. Moxon thought that in the case under observation the nutrition of the texture of the lung was probably impaired by the bad drainage, due to obstruction of the bronchial glands, and that it then was rendered liable to undergo more intense inflammation. As to the idea of blood-poisoning, he quoted the opinion of Dr. Wilkes, that in cases of inflammation of the pleura from blood-poisoning the process was always secondary to affection of the lung tissue.—*The Lancet*, January 22, 1876.

Method of Preparing Diseased Tissues for the Microscope.—Some time ago it occurred to Mr. John Stevenson that a mixture of glycerine and tragacanth might be used for the purpose of imbedding tissues, both recent and hardened. He takes two drachms of glycerine and mixes it on a slab with one drachm and a half of powdered gum tragacanth. The piece of organ to be sliced is placed in a two-dozen or smaller pill-box, and the mixture, lifted on a flexible knife, is poured into the box. It is allowed to stand in a cool place for from eight to twelve hours, when, if not wanted for cutting, the bottom is taken off the box and slit up the side, and a solid, somewhat elastic cake is obtained, with the piece of tissue imbedded in it. This is placed in methylated spirit until required. The tissue should be placed near the margin from which it is to be cut, and the cutting conducted in the usual way. It will be found best to moisten the surface by dipping it in spirit, and wetting the upper surface of the section knife with a camel's-hair pencil dipped in spirit, so that the section may float as it is cut. When it is to be kept in spirit for twelve to twenty-four hours, the mass is better mixed with two drachms of glycerine, one drachm of tragacanth powder, and fifteen grains of gum arabic powder. The properties of the mixture are quite in accordance with the chemical nature of its constituents, for glycerine dissolves gums and resins freely, being at the same time hygroscopic; and tragacanth has twenty-five times the power of ordinary gum arabic in communicating the property of viscosity to water. If the tissue has been previously in spirit, it must be steeped for a few hours in cold water before imbedding.—*Edinburgh Medical Journal*, January, 1876.

Observations on Revaccination during an Epidemic of Small-Pox.—Dr. William B. Davis, in a paper read before the Cincinnati Medical Society, comes to the following conclusions, from observations in that city during an epidemic of small-pox: *First*, That exposure to infection and intense epidemic influence largely increase the susceptibility of the system to the influence of vaccine virus, and accounts for the unusual number of successful revaccinations during the existence of an epidemic. *Second*, That variola and varioloid give no more protection from a recurrence of variola than vaccination. *Third*, The cicatrix is not a safe criterion of the degree of protection given by the vaccination from which it resulted. *Fourth*, It is advisable to revaccinate upon every exposure to infection, unless it has been done recently with success. *Fifth*, Those who were successfully revaccinated were, to some extent, susceptible to the variolous influence; not that all would have taken the infection, for an epidemic never takes all the unprotected. That they are in some danger is proven by the results of vaccinations in the hospitals and standing armies of Europe. In the Prussian army the annual death-rates from small-pox, before revaccination was introduced, averaged 104. During the twenty years immediately succeeding the establishment of systematic revaccination, there were but forty fatal cases, and Simon says, but four of these had been successful revaccinations.

The Causes and Treatment of Sleeplessness.—Dr. J. Milner Fothergill thinks the experiments of Durham, Hammond, Donders, and others, have clearly shown the relation of sleep to cerebral anæmia. This condition of anæmia is produced by the co-operation of two factors, one a modification of the vascular system, the other a diminution of activity in the cerebral cells themselves. It is the combination of these two factors in the production of sleep that must ever be borne in mind in the treatment of each case of insomnia. Sleeplessness, among other causes, is due to a condition of high cerebral vascularity. There may be a local (cerebral) hyperæmia, a general vascular excitement, and a rise of temperature. Opium alone will not meet these complex states. In order to procure its hypnotic effects, it is necessary to combine it with a direct vascular depressant. In chloral-hydrate we have a drug which acts upon the nervous system, lessens the heart's action, and lowers the temperature. But the very qualities which may here render it so valuable, constitute the objections to its use in other forms of insomnia. A different form of sleeplessness is found where patients have cerebral anæmia. Here there is sleepiness felt during the day, especially when in the upright position, but at night when the body is recumbent a state of wakefulness is instituted. Such a condition is most pronounced in melancholics. Bromide of potassium and chloral in such cases, however effective in procuring sleep, are injurious, from their tendency to aggravate the condition of anæmia. Authorities advocate, instead, alcohol and opium, accompanied by a generous diet, and by the exhibition of iron and quinine in fair quantities. There is a form of passive cerebral hyperæmia, in which insomnia is present, due to partial vaso-motor paralysis of the in-

tracranial blood-vessels, usually associated with mental overwork. One constituent factor of the treatment must be to lessen this cerebral activity by some suitable agent. Bromide of potassium, of all remedies, is the most efficient, and with it digitalis may be advantageously combined. In such cases it is the action of digitalis upon the peripheral vessels, rather than its effect upon the heart which renders it so valuable here. Dr. Fothergill, after reviewing the different forms of sleeplessness, mentions some of the chief forms of hypnotics in common use. Opium is indicated in conditions of insomnia, which originate in pain. Hyoscyamus may be resorted to in cases where opium or morphia disagree, as in chronic renal disease. Hydrate of chloral is useful in conditions of vascular excitement, either alone or in combination with opium. In cases of sleeplessness, where there is continuous high blood-pressure, or where there is distinct pyrexia, chloral-hydrate is the hypnotic *par excellence*. It is to be avoided, however, where inability to sleep is due to worry and to brain exhaustion. The utility of bromide of potassium is shown where cerebral activity is kept up by distant peripheral irritation, especially where that irritation lies in the pelvic viscera.—*The Practitioner*, February, 1876.

On Benign Polypoid Excrescences of the Bladder in the Male.—Dr. Hermann Maas, of Breslau, has recently met with three cases of mucous polypi of the male bladder, which are interesting from their rarity and from the means adopted to diagnosticate and cure them. The first occurred in a previously healthy man of fifty-three, and his only complaint was of the occasional passage of blood with his urine, particularly after taking spirituous drinks. Of late, however, the blood had come so frequently and in such large quantities as to weaken him very seriously. Careful examination revealed nothing to account for the hemorrhage. Suspecting that possibly there was a small ulceration, Dr. M. introduced a large double-current catheter into the bladder, and poured in weakly carbolized water. All of a sudden the outward flow of water was arrested, and on withdrawing the catheter, which required some little effort, a mucous polypus, pedunculated, and of the size and shape of a small hazel nut, was found engaged in its eye. On a second attempt Dr. M. was fortunate enough to secure a second polypus in the same way, and after its removal there was no return of the hemorrhage. The second case was in an officer of thirty-three, who had suffered for some years from a stricture of the membranous urethra, which had been very irregularly treated. His history was that at times he had had attacks of complete retention of urine, which had been relieved by the passage of smaller bougies and had been called "spasmodic." Dr. M., when he first saw him, could pass a No. 5 Charrière, and soon was able to increase it to No. 9. All of a sudden the urine was arrested, and could not be made to flow until a catheter of corresponding size had been several times passed well into the bladder. Being unable to diagnosticate a stone, and remembering the last case, the doctor endeavored to entrap the polypus he suspected by similar means. As the circumstances of this case forbade the use of the double catheter, he introduced a No. 8 elastic English catheter, after enlarging its eye. This was connected by rubber tubing with a ⊥ shaped glass tube, and by means of a funnel the bladder was fully distended with warm carbolized water. Depressing, then, the outer end of the tube, gravity, aided by the expulsive force of the bladder, caused a rapid flow of water, and after several trials the suspected polypus was engaged and removed. It was 17 mm. long and 7 thick. There was no further retention. The third case was almost precisely similar to the second, the polypus being the size of a strawberry.—*Berl. Klin. Woch.*, Jan. 24, 1876.

Alkaptonuria.—The following observations on a case where alkapton was found in the urine are reported by Dr. Fürbringer, from the Clinique of Prof. Friedreich. The patient was a consumptive in an advanced stage of the disease, and the urine, which was scanty, of a dark color, acid reaction, and of normal specific gravity when treated with Trommer's test, showed a precipitate of the red and yellow oxides of copper, though no sugar was present. The dark color, which was due to the presence of an unusual amount of urophæin, was ascribed to co-existing chronic disease of the liver. Proof of the existence of alkapton, which was suspected, was found in the absorption of oxygen when the diluted urine was agitated with caustic potash. The absence of sugar was determined by first precipitating with an abundance of acetate of lead, and then testing the filtrate by Trommer's method, for the alkapton is carried down with the precipitate. This then will be found the best method of eliminating alkapton from any suspected fluid, and afterwards determining the presence or absence of sugar. Thus tested, there was not the slightest trace of reduction of the copper salt. Various other tests corroborative of the absence of sugar, and the presence of alkapton were employed, notably Böttger's, depending on the reduction of a bismuth salt, the fermentation test, Mulder's indigo test, and the silver and quicksilver test. A number of others are also referred to of interest to the chemist. Several were also rendered ineffectual by the large amount of coloring matter contained in the urine. The post-mortem examination was made by Dr. Thoma, and nothing of special significance was found. No anomaly was discovered in the urinary passages, nor was alkapton found in any other fluids of the body. Hence Dr. F. concludes that alkapton is first formed in the secreted urine within the organism. Boedeker's case is the only other one which the author can find reported, and in the absence of a larger number for comparison, the presence of alkapton in the urine remains wholly unexplained.—*Berl. klin. Woch.*, June 7 and 14, 1875.

A Case of Splenic Fever.—The following case is reported by Prof. Bollinger, of Munich. A cow was sick, and although, when she was killed, the intestines were found full of blood, and the spleen four times its natural size, still the flesh was eaten by men. A few days later the butcher observed a small red spot on the ball of his right thumb, which soon acquired a red areola and a dark-blue vesiculation. At the end of four days, when general symptoms with great depression had appeared, the sore was cauterized with the hot iron. Nevertheless, the man died on the eighth day, after having convulsions, trismus, high fever, etc., At the autopsy the characteristic features of a splenic fever carbuncle were found in the arm, viz., dark coloration with red areola and distinct vesicles, together with oedematous swelling of the the lymphatic glands. There was also hemorrhagic effusion into the stomach. Many bacteria were found in the spleen, but few in the carbuncle or in the blood. Inoculations of the blood upon sheep caused their death in from two to five days, with pronounced symptoms of apoplectiform anthrax; nor did the addition of salicylic acid serve to disinfect the poisonous blood. *Aerztlich. Int. Bl. No.* 4, 1876.—*Allg. Med. Cent. Zeit.*, Feb. 2, 1876.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

PUBLISHED BY

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, March 25, 1876.

THE PROGRAMME OF THE INTERNATIONAL MEDICAL CONGRESS.

THE Centennial Medical Commission has, through its Committee of Arrangements, so far perfected its plan of the work to be accomplished during the week ending September 9th at Philadelphia, as to be able to publish its preliminary programme. We can well appreciate the amount of thought and labor expended in making the various features of the entertainment blend and harmonize into one uniformly attractive whole. We infer from the employment of the qualifying term "preliminary," that the programme is as complete as it is now possible to make it; but that it may still admit of extension by additions, possibly from foreign sources. Indeed, it must be very difficult at the outset to impress upon gentlemen from abroad the urgency of these early preparations for a great undertaking, and the necessity of immediate responses to the solicitations of a Secretary or a Committee. A Congress to meet six months from this date should be more than a mere outline to-day. Happily, this Congress has long since advanced beyond the shadows of coming events, and has already passed into a structure of a very substantial character, indicating clearly the scope of its practical work and its various projected paths of usefulness.

The almost total absence of foreign names strikes one at a glance, that of Prof. Lebert of Breslau University being the only one upon the list. This is no fault of the Committee, however; for we learn that other gentlemen have been invited to address the Congress and have declined. It was part of the original plan of the Commission, that four addresses should be delivered by distinguished foreigners, before the Congress in its entirety, at the morning session. It is of course impossible to carry this feature into execution, if gentlemen who may be selected are unable to accept; but there is plenty of opportunity offered for good volunteer papers from medical men the world over. These may be even more provocative of discussion than those already included in the programme of work of the sections, of which there are nine. While it is absolutely essential to the success of such a Congress that the labor should be systematically prepared beforehand, a great deal of the interest attached to the sectional discussions in the American Medical Association has resulted from their spontaneousness. Much more sparkle is associated with such voluntary efforts, and a greater amount of agreeable effervescence constantly bubbles up to the surface under their influence.

The programme of addresses before the general Congress embraces an excellent selection of representative men, judiciously apportioned from various localities. There is no very good reason, however, why Philadelphia should have so thoroughly ignored her own just claims to a prominent place upon the list. She was certainly entitled to one representative man in this portion of the programme. It would be an act of injustice to her, and to her excellent corps of able and active thinkers and workers—many of whom have adorned the paths of professional labor, and of medical literature—if the inference should be drawn by foreign visitors or readers, or even by our fellow-countrymen, that any lack of originality, or of ability was the cause of such exclusion. Our friends in that city who have arranged the programme of the congress have only themselves to blame if their modesty has been carried to the extent of self-immolation. Even in the work of the sections we find the names of but four Philadelphians out of the thirty-five who are to open the discussions on scientific subjects. New York, in addition to her representation in the list of morning addresses, supplies the names of fourteen reporters for the section. Their names will be found in another column. Only four subjects will be discussed in each section, one being allotted to each afternoon. There will then be abundant opportunities for the presentation of voluntary papers; the fifth day, it is presumable, being also devoted entirely to them. Hundreds of distinguished men in all portions of the world will be invited to attend the sessions of the Congress. It is to be hoped that the responses will be of such a nature as to make this meeting a memorable one by the presence of numerous representatives of science, learning, and skill from foreign countries as well as from our sister states of the Union.

"SHALL IT BE A PROFESSION OR A TRADE?"

IT will not be forgotten that, on more than one occasion, we have impressed upon our pharmaceutical friends the importance of regarding themselves as members of a worthy profession, which should be elevated beyond and above the baser considerations and temptations of trade. We shall be gratified if, as a result of the

proper digestion of this food for reflection which we have given them, pharmacy shall attain the elevated rank it deserves to occupy. We are fortified in the correctness of our views, when we find them endorsed by one of the oldest colleges of pharmacy in the country—that at Philadelphia. In his valedictory to the graduating class of that school, delivered March 14, 1876, Prof. Joseph P. Remington employed the following language, which is almost identical with that of the RECORD (in its editorial, Oct. 9, 1875, "Shall it be a Profession or a Trade?") in its allusion to the same topic: "A very important subject must soon be solved. Do you regard your avocation as a profession or a mere business calling? * * * You must make a decision. What shall it be? Profession or trade, pharmacy or a black art, pharmacopœia or price current?" These queries, coming from such an authoritative source as the rostrum of the College, were doubtless well received. They are our own, and we therefore return the compliment, and ourselves endorse them.

THE EAGLEY EPIDEMIC.

THE account of the Epidemic at Eagley, which we are enabled to give in another column, is a suggestive comment upon the dangers to which every one who uses milk may become exposed. If the present example were an isolated one, we might offset the apparent sensationalism connected with it. It is true, instances of the sort are not common, but this should not deter us from appreciating them when they do occur, and guarding as much as possible against their recurrence. How this latter can be accomplished is a problem which is engaging the attention of the legislators of Great Britain; and it is now quite possible that some means will be adopted by the English Government to prevent a repetition of such wholesale poisoning. Probably the only thing that can be done in this direction is a periodic inspection of all dairy farms. Doubtless in this country any enactments having such an end in view, would be looked upon as an unnecessary refinement in sanitary science; but its reasonableness can hardly be denied by any one who is willing to admit the possibility in any dairy district of a similar set of causes as those operating at Eagley producing similar results. Until we look into the whole matter of our milk supply, it is impossible to conjecture how many cases of fever, diarrhœa, and various anomalous and apparently inexplicable symptoms, may not be traced to the admixture, accidental or designed, of putrid material in the water used. At this time, when such a general interest is manifested in the subject, it may be a matter of curiosity, if not of profit, for some of our readers residing in the rural districts, to study the causation of some of the fevers and diarrhœas which they may be called upon to treat in connection with the water supply of the barn yard and the dairy.

THE CARE OF THE INSANE.

DR. H. B. WILBUR, the accomplished Superintendent of the Syracuse Idiot Asylum, has just submitted a report to the State Board of Charities founded upon personal observations concerning the management and construction of the insane asylums of Great Britain, in which is embodied some interesting conclusions bearing upon the care of the insane in our own country. From an economic point of view the cost of the construction of our asylums does not bear a very flattering comparison. Dr. Wilbur found that the Commissioners of Lunacy gave the maximum cost of construction as £150, or about $750. per patient, including land and furniture. In Massachusetts, on the other hand, the cost of two asylums in the course of construction is estimated at the enormous sum of from $2,500 to $3,000 per capita; while one in New Jersey, also being built, is fully up to the last high figure, and the three asylums in process of erection in this State will range from $4,000 to $5,000 per patient. Regarding the cost of maintenance of each patient after his or her reception, there appears to be a similar difference, in this State at least, in favor of the economy of management in the British asylums. For instance, in the three State Lunatic Asylums in this State the average weekly cost of maintenance exceeds six dollars for each patient. In one of these institutions, during 1874, it even exceeded that amount. On the other hand, the average cost per patient in the county asylums in England, institutions corresponding to our State Asylums, is less than three dollars, including clothing; and in like asylums in Scotland and Ireland considerably less. These are very important facts for the consideration of every one interested in the economical and yet proper care of our insane.

From this point of view, at least, we have something to learn from our transatlantic cousins. On a previous occasion we alluded to the beneficial effects of engaging the patients in some sort of employment; and we again take the opportunity of referring to the matter, by way of showing the actual per cent. of those who can be placed under such influences. In this country the employment system has gone so much out of fashion that we are almost without statistics for comparison. The Utica Asylum, however, furnishes a starting point by showing that the average of male labor was less than eighteen per cent. of the entire number of male inmates. Dr. Wilbur found in the English asylums which he visited that the employed patients averaged fully sixty-two to sixty-eight per cent., while the percentage in Scotland was even greater. This gives us a very marked difference in figures; and, taken in account with the statement that the patients "are a better-looking set physically than the patients in some American asylums," is, to say the least, quite suggestive. In this connection we may quote the following statement as having a significant bearing in this connection:

"Within a few years, in a certain Scotch asylum where the employment of patients had been pushed to its maximum, the sagacious and kind-hearted Superintendent thought that he would try the experiment of unlocking the doors of one of his best wards and patrolling the patients. This worked well; he tried the next, and so on till a large degree of personal liberty was enjoyed by nearly all the patients. Though the Superintendent, Dr. Batty Tuke, has retired from this asylum, his successor, Dr. Fraser, has administered its affairs in the same benevolent spirit."

We will also remind our readers, in passing, of more unequivocal testimony as to the benefits of the employment system, which is embodied in the extract from a letter of Dr. Wilbur, to which reference was made in our recent comments upon the paper of Dr. Nathan Allen on *State Medicine in its relations to Insanity* (*vide* vol. x., page 41).

In regard to extravagance in the construction of our asylums, Dr. Wilbur very truly says:

"There is in Great Britain a safeguard against squandering money on buildings that, most unfortunately, does not apply in the construction of State Asylums in America. It is this: the tax to meet such outlay is drawn from the same locality where it is expended, and the members of the boards of management are among the largest tax-payers of the region. Thus, their own pecuniary interests, and a sense of responsibility to an immediate constituency, equally interested together, act as a strong check against extravagance."

We have, however, said enough to give the general drift of the report, and will close by quoting the conclusions of Dr. Wilbur:

"That in this country the welfare and comfort of the insane, and the various correlated interests of society, would meet on common ground, not until every State in the Union had some legally constituted board, alike in powers and functions to those of the British Boards of Lunacy."

There are many other very interesting matters referred to in the report which we shall take occasion to notice at some future time.

OVERCROWDED SCHOOLS.

We are pleased to learn that the Committee on By-Laws of the Board of Education have given the subject of overcrowding in the public schools such a consideration as its importance demands. They very frankly admit that the evil of which so much complaint has been made exists to an alarming extent, and show a very commendable spirit to remedy it as far as it may lay in the power of the Board. They make a provision for increased capacity for each scholar, which, although it is still inadequate, is still a great improvement of the former condition of things. The following sensible regulation was recommended and adopted:

"It shall be the duty of every principal to reject all applications for the admission of pupils into any school or class, whenever the room occupied by the same is filled to the extent of its sitting capacity."

PROPOSED AMENDMENTS TO THE PHARMACY BILL.

In the year 1872 the Legislature of this State enacted a law to regulate the practice of Pharmacy and the sale of poisons in the city and county of New York. It is within the recollection of many of our present readers that this law was the result of a determination on the part of the pharmacists in this city, represented by the College of Pharmacy, not only to supersede the one at that time in force but to improve the status of pharmacy in general by the establishment of a system of registration which should ensure qualification and responsibility on the part of every one who dispensed medicines. Through the energy of Senator Weismann and the hearty co-operation of Assemblyman Loughran the desired result was obtained, and since that time the working of the law has been in the main satisfactory. One of its provisions was to the effect that the members of the college should elect five competent pharmacists, three of whom should be also graduates in medicine, and two graduates of the college, who should constitute a board for the examination and registration of all those not already graduates and not already licensed, who desired to conduct the business of pharmacists. Experience has now proved that the difficulty of constituting the board in accordance with the letter of the law is so great that an amendment has been offered to remedy it. The latter consists in a recommendation that the said board shall be composed entirely of graduates in pharmacy, the reason for this being that it is exceedingly difficult to find a sufficient number of physicians who, being competent for the appointment, are willing to act.

Another amendment consists in a provision that, from the first of July, 1878, only graduates in pharmacy from an American or foreign College of Pharmacy shall be allowed to establish themselves in the city and county of New York; and that after 1878 the board shall restrict itself to the examination of candidates for a licentiate's degree.

It is also proposed that the clause in the present law that junior assistants or apprentices shall not be permitted to prepare physicians' prescriptions until they have become graduates or licentiates, be so amended as to give all such persons opportunity to dispense prescriptions under the supervision and upon the responsibility of their principals. A bill embodying these provisions, presented to the State Senate by Senator Booth, has already passed that body, and will soon come before the Assembly for its action. The changes proposed in the present law have received the sanction of all the leading pharmacists of this city, and there is every reason to suppose that the Assembly will follow the lead of the Senate.

If this be the case, we shall doubtless have a law for the regulation of pharmacy in this city and vicinity which shall be as near perfection as ordinary legislation can make it. The profession are certainly enough interested in the result to throw the weight of its influence in the scale.

Correspondence.

THE ELECTROLYTIC TREATMENT OF MALIGNANT TUMORS.

To the Editor of The Medical Record.

Sir:—I am not in the habit of entering a journalistic controversy, especially when the assailing person, the critic, is unwilling to sign his name. In the first place, such polemics never promote scientific knowledge; and besides, very few readers take the trouble to examine the facts, thus leaving much room for incorrect statements and vague insinuations.

My critic, C. E. H., in the last number of the Record, intentionally tries to confuse the readers by mixing up different articles written by me on different subjects, at different times, and in different places, reviewing them as "*a part of the same work*," adding in parenthesis, very adroitly, for any future emergency, that he supposes so. The critic acknowledges, however, that he owns my "*Galvano-Therapeutics*," and therefore he ought to know that it contains only articles on the auditory, sympathetic, and pneumogastric nerves. At the time of their publication, they supplied a want in the American medical literature; and, besides containing original researches, gave a complete, though concise exposition of our knowledge on these subjects.

The critic quotes a few phrases from my researches in *Virchow's Archives*, where on the first page I say, that I published, some years ago, a short preliminary notice on the electrolytic treatment of malignant tumors, that gave rise to misunderstandings; but he does not explain that the very article from which he quotes is the one containing a full and minute exposition of my views and methods. He thus leaves the reader under the wrong impression, that I had not fulfilled my promise.

If the critic has really read my researches in Virchow's Archives, he ought to be the last to complain that "*I do not go into minutiæ, &c.*," as I have given a most detailed account of my cases, and an exhaustive exposition of my views and my methods of treatment. He refers to the case of Mrs. H., which I mentioned merely as a corollary to the preceding case described on five pages, and to the following one described on four pages. His quotation as regards the treatment is of no practical use without a general knowledge of the whole theory. But even in these few lines, the critic misquotes me, and is incorrect.

The last fault the critic finds with me, is that I published my researches *in extenso* in German, while I gave only a short resume for American physicians. But this has certainly been against my will.

I herewith, Mr. Editor, send you for inspection the English manuscript of my researches on the electrolytic treatment of malignant tumors, a monograph containing more than one hundred and thirty pages, certainly too voluminous to be published in a medical weekly.

An American journal refused to publish these researches; and I have asked in vain for an opportunity to read my paper before the Academy of Medicine, but the late president denied me this opportunity, on the ground, as he wrote me at the end of two years, that the subject did not present sufficient interest, and added, to enable me "to accumulate more interesting facts."

Truly the old French adage can still justly be applied to those learned critics who scarcely ever make original researches: "la critique est aisée, mais l'art est difficile." Yours very truly

Wm. B. Neftel.

DEATH FROM RUPTURE OF AN ANEURISM—SUPPOSED CAUSE, PENETRATING WOUND OF THE HEART.

To the Editor of The Medical Record.

The first officer of a merchant ship, during an altercation with one of his men, received a stab in the chest with a sheath-knife and fell back dead.

Being summoned to the case, we found the man, as had been reported, laying on the ship's hatch lifeless.

On baring the chest there was disclosed a wound an inch long on the left third intercostal space, directly over the heart.

Having no other idea than that the instrument had penetrated the organ, and was the immediate cause of death, we reported the case to the coroner.

On making a post-mortem we found that the knife had barely passed into the cavity of the chest, and was consequently not the cause of death, as had been supposed.

A further examination, however, disclosed a ruptured aneurism of the pulmonary artery, the immediate cause of which was doubtlessly the excitement of the scuffle and the shock of the blow from the knife.

The two points of special interest in connection with this case are:—

1st. The location of the aneurism. As Flint, in his chapter on thoracic aneurisms, does not mention a single case as occurring in the pulmonary artery, we concluded it must be rare.

2d. The medico-legal question which might arise, as to the degree of criminality of the assailant. It is clear that, had there been no post-mortem, the case would have been declared one of murder in the first degree.

The revelations of the autopsy, however, converted it into a simple assault with a deadly weapon; at least such was the wording of the indictment, which was carried out by the decision of the court, as the prisoner received some six or eight months only.

D. B. Simmons,
Chief Surgeon to Ken Hospital, Yokohama, Japan.

Yokohama, Japan, *January*, 1876.

College of Pharmacy of City of New York.—The Forty-Sixth Annual Commencement was held on Tuesday evening, March 21st, 1876, at Chickering Hall. After the opening address by the President, Paul Balluff, the degree of "Graduate in Pharmacy," was conferred upon thirty-nine gentlemen. Prof. P. W. Bedford awarded the alumni prizes: the first, a gold medal, to Henry C. Schrank; the second and third of equal value, and for equal grades, to Adolph Henning and Henry Millar. Prof. Edward Curtis, M.D., delivered the address to the graduates, after which the valedictory was pronounced by H. Lieber Coit, of the Graduating Class.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department United States Army, from February 12th to February 18th, 1876.

MILHAU, J. J., Surgeon.—Leave of absence extended four months. S. O. 49, A. G. O., March 13, 1876.

FORWOOD, W. H., Asst. Surgeon.—Granted leave of absence for one month, with permission to leave limits of the Department. S. O. 43, Department of Texas, March 11, 1876.

ADAIR, G. W., Asst. Surgeon.—Assigned to temporary duty as Post Surgeon at Fort Richardson, Texas. S. O. 43, C. S., Department of Texas.

MAUS, L. M., Asst. Surgeon.—When relieved at Nashville, Tennessee, by Asst. Surgeon Greenleaf, assigned to duty as Post Surgeon at Chattanooga, Tenn. S. O. 39, Department of the South, March 16, 1876.

Medical Items and News.

INTERNATIONAL MEDICAL CONGRESS, Philadelphia. Preliminary Programme.—The Congress will meet at noon, on Monday, September 4th, 1876, in the University of Pennsylvania. The following addresses will be delivered in general meeting:—On Medicine, by Prof. Austin Flint, M.D., New York. On Hygiene and Preventive Medicine, by Henry I. Bowditch, M.D., of Massachusetts. On Surgery, by Prof. Paul F. Eve, M.D., of Nashville. On Obstetrics, by Prof. Theophilus Parvin, M.D., of Indiana. On Medical Chemistry and Toxicology, by Prof. Theodore G. Wormley, M.D., of Columbus, Ohio. On Medical Biography, by J. M. Toner, M.D., of Washington, D. C. Address, by Prof. Hermann Lebert, of the University of Breslau. On Medical Education and Medical Institutions, by Prof. Nathan S. Davis, M.D., of Chicago. On Medical Literature by Prof. L. P. Yandell, M.D., of Louisville. On Mental Hygiene, by John P. Gray, M.D., of Utica, N. Y. On Medical Jurisprudence, by Prof. S. E. Chaillé, M.D., New Orleans. Discussions on Scientific Subjects will be opened in the sections as follows:—

SECTION I. MEDICINE.—Typho-malarial Fever; is it a special Type of Fever? J. J. Woodward, M.D., Assistant-Surgeon, U.S.A. Are Diphtheretic and Pseudo-membranous Croup Identical or Distinct Affections? J. Lewis Smith, M.D., of New York. Do the Conditions of Modern Life favor specially the Development of Nervous Diseases? Prof. Roberts Bartholow, M.D., Medical College of Ohio. The Influence of High Altitudes on the Progress of Phthisis. Charles Denison, M.D., of Denver, Colorado.

SECTION II. BIOLOGY.—Microscopy of the Blood. Prof. Christopher Johnston, M.D., of Baltimore. The Excretory Function of the Liver. Prof. Austin Flint, Jr., M.D., of New York. Pathological Histology of Cancer. Prof. J. W. S. Arnold, M.D., of New York. The Mechanism of Joints. Prof. Harrison Allen, M.D., of Philadelphia.

SECTION III. SURGERY.—Antiseptic Surgery. Prof. John T. Hodgen, M.D., of St. Louis. Medical and Surgical Treatment of Aneurism. Prof. William H. Van Buren, M.D., of New York. Treatment of Coxalgia. Prof. Lewis A. Sayre, M.D., of New York. The Causes and Geographical Distribution of Calculous Diseases. Claudius H. Mastin, M.D., of Mobile, Ala.

SECTION IV. DERMATOLOGY AND SYPHILOLOGY.—Variations in Type and in Prevalence of Diseases of the Skin in Different Countries of Equal Civilization. Prof. James C. White, M.D., of Boston. Are Eczema and Psoriasis Local Diseases, or are they Manifestations of Constitutional Disorders? Lucius Duncan Bulkley, M.D., of New York. The Virus of Venereal Sores; its Unity or Duality. Prof. Freeman J. Bumstead, M.D., of New York. The Treatment of Syphilis, with Special Reference to the Constitutional Remedies appropriate to its various Stages; the Duration of their Use, and the Question of their Continuous or Intermittent Employment. Prof. E. L. Keyes, M.D., of New York.

SECTION V. OBSTETRICS.—The Causes and the Treatment of Non-puerperal Hemorrhages of the Womb. Prof. William H. Byford, M.D., of Chicago. The Mechanism of Natural and of Artificial Labor in Narrow Pelves. Prof. William Goodell, M.D., of Philadelphia. The Treatment of Fibroid Tumors of the Uterus. Washington L. Atlee, M. D., of Philadelphia. The Nature, Causes, and Prevention of Puerperal Fever. Prof. William T. Lusk, M. D., of New York.

SECTION VI. OPHTHALMOLOGY.—The Comparative Value of Caustics and Astringents in the Treatment of Diseases of the Conjunctiva, and the Best Mode of Applying them. Prof. Henry W. Williams, M. D., of Boston. Tumors of the Optic Nerve. Hermann Knapp, M. D., of New York. Orbital Aneurismal Disease and Pulsating Exophthalmia; their Diagnosis and Treatment. Prof. E. Williams, M.D., of Cincinnati. Are Progressive Myopia and Posterior Staphyloma due to Hereditary Predisposition; or can they be induced by Defects of Refraction, acting through the Influence of the Ciliary Muscle? E. G. Loring, M. D., of New York.

SECTION VII. OTOLOGY.—Importance of Treatment of Aural Diseases in their early Stages, especially when arising from the Exanthemata. Albert H. Buck, M.D., of New York. What is the Best Mode of Uniform Measurement of Hearing? Clarence J. Blake, M.D., of Boston. In what Percentage of Cases do Artificial Drum-membranes prove of Practical Advantage? H. N. Spencer, M.D., of St. Louis.

SECTION VIII. SANITARY SCIENCE.—Disposal and Utilization of Sewage and Refuse. John H. Rauch, M.D., of Chicago. Hospital Construction and Ventilation. Prof. Stephen Smith, M.D., of New York. The General Subject of Quarantine, with Particular Reference to Cholera and Yellow Fever. J. M. Woodworth, M.D., Supervising Surgeon-General U. S. Marine Hospital Service. The Present Condition of the Evidence concerning "Disease germs." Thomas E. Satterthwaite, M.D., of New York.

SECTION IX. MENTAL DISEASES.—The Microscopical Study of the Brain. Walter H. Kempster, M.D., of Oshkosh, Wisconsin. Responsibility of the Insane for Criminal Acts. Isaac Ray, M.D., of Philadelphia. Simulation of Insanity by the Insane. C. H. Hughes, M.D., of St. Louis. The Best Provision for the Chronic Insane. C. H. Nichols, M.D., of Washington, D. C.

Gentlemen intending to make communications upon scientific subjects, or to participate in any of the debates, will please notify the Commission before the first of August, in order that places may be assigned them on the programme.

In order to facilitate debate, there will be published

on or about June 1st the outlines of the opening remarks by the several reporters. Copies may be obtained on application to the Corresponding Secretaries.

The volume of Transactions will be published as soon as practicable after the adjournment of the Congress.

The public dinner of the Congress will be given on Thursday, September 7th, at 6.30 P. M.

The registration-book will be open daily from Thursday, Aug. 31, from 12 to 3 P. M., in the Hall of the College of Physicians, N. E. corner 13th and Locust Streets. Credentials must in every case be presented.

The registration fee (which will not be required from foreign members) has been fixed at Ten Dollars, and will entitle the member to a copy of the Transactions of the Congress.

Gentlemen attending the Congress can have their correspondence directed to the care of the College of Physicians of Philadelphia, N. E. corner of Locust and Thirteenth Sts., Philadelphia, Pennsylvania.

There is every reason to believe that there will be ample hotel accommodation, at reasonable rates, for all strangers visiting Philadelphia in 1876. Further information may be obtained by addressing the Corresponding Secretaries.

All communications must be addressed to the appropriate Secretaries at Philadelphia.

S. D. Gross, M. D.,
President.

William B. Atkinson, M.D., 1400 Pine Street, *Recording Secretary.* William Goodell, M.D., 20th and Hamilton Sts., Daniel G. Brinton, M.D., 115 S. 7th Street, *American Corresponding Secretaries.* Richard J. Dunglison, M.D., 814 N. 16th Street, R. M. Bertolet, M.D., 113 S. Broad Street, *Foreign Corresponding Secretaries.*

Philadelphia, March, 1876.

The "Milk Epidemic" at Eagley, to which we have made reference two weeks since, is still causing a great deal of sensation in England and awakening a considerable amount of interest in medical circles in regard to its origin. As the result of a thorough investigation on the part of the health authorities, it seems that the fever—a mild form of typhoid—was clearly traceable to milk contaminated with water which was "so foully polluted as to render it little better than liquid sewage." It seems from more detailed reports which comes to us from across the water, that the earliest case was brought before the notice of the local authorities on Wednesday, the 9th of February, and that before the following Saturday evening there were between eighty and ninety persons confined to their beds with fever, eleven of whom eventually died of it. The suddenness and violence of the attack and its limitation to a small locality naturally suggested some local cause, and investigations were at once instituted to discover it. Eagley does not contain more than five hundred inhabitants, and the majority of these are employed in some tape and cotton thread works which are built on the stream running through the valley and passing by the lower part of the hamlet. It was soon discovered that in every case of sickness during the epidemic, the sufferers had been accustomed to drink milk from one particular farm, while those who had not been in the habit of drinking that milk, although living in the same house, invariably escaped the disease. A visit was next made to the farm, which showed that the milk cans were always washed with water from a brook which ran by a mill in course of construction, and that the workmen employed in the latter work had, for want of better conveniences, deposited their excrement upon the banks, whence the said excrement was washed into the stream by every fall of rain. The milk had been in this manner evidently contaminated with sewage matter. An examination of the water in the tubs left little doubt as to its sewage contamination, as it contained large quantities of free ammonia, albumenoid ammonia and chlorine.

The *Medical Press* and Circular (Mar. 1), in a leading article upon the subject from which we have condensed the above facts, says:—

"But as far as the etiology of typhoid fever is concerned, the great question is, whether this sewage-contamination was or was not of a specific nature. In most outbreaks of this kind, the water has been found to have been polluted with fever evacuations, and a more strict investigation will be necessary before it can be said that such was not the case in the Eagley epidemics. At all events, this and similar outbreaks show the necessity of ensuring the purity of all water that is used in dairy farms, and in the premises of all milk-venders."

Uniformity of Weights and Measures.—Dr. E. Seguin of this city, who has within the past three or four years given a great deal of attention to the development of an idea to establish a unity of method in scientific observation throughout the world, proposes through the next International Medical Congress to infuse a more practical interest into the subject among medical men throughout the world. After referring to what has already been done in advocating the claims of such a uniformity of system, he says:—

"In furtherance of these antecedents, it is now proposed to submit the same question to the next International Medical Congress—to ask the Congress to constitute National Commissions, similar to the French one, which has volunteered its services in Paris; to appoint the next meeting of the International Medical Association, as the place where these Commissions will present a joint report on the most practical means of *uniformising* the methods, instruments, and records of observation; to consider the feasibility of this plan in connection to—but not by confounding it with—the adoption of the French Metric System; to entrust all the executive measures demanded for the realization of this plan to Dr. W. B. Atkinson, the General Secretary of both the American and the International Associations."

Slaughtering-Houses.—The Health Commissioners, as the result of a recent tour of inspection of the different slaughtering-houses of this city, suggest that on the east side the butchers erect a capacious building near the water's edge, provided with all the modern improvements to preserve cleanliness and prevent waste of blood and the other matter now carried off by the sewers. This waste material can be made into fertilizers worth $40 a ton. They maintain that no matter how much pains the butchers may take, they cannot profitably conduct a small slaughter-house in such a manner that it would not prove detrimental to the health of those living in the neighborhood. On the west side the butchers could hire "baulks" in the abattoir at the foot of Thirty-fourth street, or unite and build such a building as is suggested for the east side. They are, therefore, convinced that the best interests of the city demand the removal of slaughter-houses beyond the more thickly inhabited quarters, and they will call for the enforcement of the ordinance that limits their remaining below One-hundred-and-tenth street to July 4, 1876.

Medical Relief Tickets.—The New York Orthopædic Dispensary and Hospital issue recommendations in blank for physicians who may desire to send any of their poor patients for treatment. A surgical clinic is held every Wednesday at 2 P. M., and an orthopædic clinic every Friday at 2 P. M.

The Italian Medical Association is to be held in Turin, commencing September 18th, 1876.

Religious Insanity.—Dr. Gray, of the Utica Insane Asylum, declared, some time ago, that he had yet to see a case of insanity which could be clearly traced to religious excitement as its cause. Rather a remarkable statement; but it must be recollected that his patients coming, as they do, from New York, are not very susceptible to such exciting causes.

Centennial Exhibition.—Dr. William Pepper, of Philadelphia, has been chosen medical director of the Exhibition.

Medical Colleges of Philadelphia.—The Jefferson Medical College of Philadelphia, held its commencement exercises on Saturday, March 11th, at 12 M., in the Academy of Music. One hundred and forty-one gentlemen received the diploma of Doctor of Medicine. Dr. Addenell Hewson presented to the college, in behalf of the Alumni Association, a portrait of the late Prof. Dunglison, after which Prof. Pancoast delivered the valedictory address.

The University of Pennsylvania, medical department, held its commencement exercises March 10th, in the same place. There were 124 graduates. The valedictory was delivered by Prof. Alfred Stillé.

Dr. Henry F. Askew, of Wilmington, Delaware, died of apoplexy, March 5th, 1876, aged 76 years. He was a successful practitioner, an ardent and leading politician, and was at one time named for Governor of his State, and at another time United States Senator. Both of these nominations he declined. In 1867 he received the high honor of an election as president to the American Medical Association.

Hospital Appointments.—In Dublin large premiums are paid for hospital appointments. In the Jervis st. Hospital five hundred pounds sterling—three hundred to the foreman incumbent and two hundred to the hospital—is said to be the customary sum.—*Philadelphia Medical Times.* Some of our friends in New York have paid more than that to secure a simple professorship.

The Presbyterian Hospital Affair.—The *London Medical Examiner*, at the conclusion of a lengthy editorial on the subject, says: "It amounts to this, that unless the members of the medical staff consent to be the creatures of the Board, to have no opinion of their own, and to think, and speak, and vote according to the ascertained wishes of the leading member of the Board, they are to be cashiered. A secret tribunal—a star-chamber—is to be constituted, in which personal pique is to arraign and condemn unheard, and without appeal, all whose views are suspected to be at variance with those of the judges; private information being accepted, and trial by jury being set aside. A more monstrous claim than this to be made in the nineteenth century by the managers of any hospital we cannot conceive, but it is only a little more astonishing than the fact that eleven medical men in New York have been found willing to accept office at the hospital under such conditions. The candidature of these gentlemen is greatly to be regretted, because it strengthens the Board in the maintenance of a position morally untenable, and weakens injuriously the influence of the medical staff as a body. All who are acquainted with the management of hospitals must be aware that there are occasions when it becomes necessary for the medical staff to oppose some contemplated action on the part of the lay authorities, or to support with all the weight of their united influence some improvement or alteration which the Board may be unwilling to effect. These are the occasions when union is shown to be strength, and disunion is equivalent to disregard and defeat."

Effect of Extreme Cold on Mind and Body.—M. Payer, the eminent Arctic explorer, referring to a certain day on which the thermometer indicated 58 Fah. below zero, says that so great an amount of cold paralyzes the will, and that, under its influence, men, from the unsteadiness of their gait, their stammering talk, and the slowness of their mental operations, seem as if they were intoxicated. Another effect of such cold, mentioned by M. Payer, is a tormenting thirst, which is due to the evaporation of the moisture of the body. It is unwholesome, too, to use snow to quench the thirst, as it brings on inflammation of the throat, palate, and tongue; besides, a temperature of 35½° to 58° below zero, Fah., makes it taste like molten metal. Snow-eaters in the North are considered as feeble and effeminate, in the same way as is an opium-eater in the East.

The Use of Well-Water in the Cities.—The State Geologist of New Jersey, in his recent report, calls attention to the habit still in use in some of the older cities of New Jersey, of people drawing their supplies of water from old wells. In an analysis of the water coming from some nine wells in Princeton, five of them were found to contain free ammonia, albuminous matter, and chlorides in excess. In tracing the effects of these waters, it was found in almost all cases that diarrhœa and typhoidal fevers accompanied their use. It is almost impossible to be sure of the good quality of any well which is surrounded by houses, where drains and sinks empty into the surrounding soil. It would be well if not only the proprietors of large country hotels of summer resort would look more closely to their sources of water, but should eschew well-water entirely. For the health of their guests, it is better in all cases, where running water does not exist, to seek their source of water from cisterns which are fed from the rain-fall on the roofs. Wherever such rain-water is used it may be safely stated that there is an entire exemption from the diseases which always attend the use of water contaminated with putrefying organic matter.

Infant Mortality.—*Le Bulletin Français* has called attention to a plan which has in view a diminution of the extraordinary death-rate among infants. It is stated that among 100 individuals in France there are reckoned only 2.55 births, while in Russia there are 4.77. Other countries offer intermediate proportions. Thus 100 marriages in Prussia give 460 infants; in France, only 300. The annual excess of births over deaths calculated for a million inhabitants is in Norway and Prussia about 14,000; in Russia and Sweden about 12,000; in Spain and Portugal, 8,500; and in France only 2,400. It appears from such statistics that the population of France would double in 170 years, while 42 years would suffice for Prussia, 52 for England, and 66 for Russia. Worse than this, however is the fact, as stated by M. Brochard, that 100,000 nurslings annually die in France from starvation and misery. It appears, too, that while infants who are

nursed by their mothers or by wet nurses at home die during the first year in the proportion of 8 or 10 in 100, those who are placed away from home, under hospital care and municipal direction, give a mortality of 30 to 36 in 100, and those who are intrusted to nurses in the provinces show the enormous mortality of from 50 to 70 in 100. With the design of developing maternal nursing, therefore, and of caring for the nursling when it has to be removed from the family, there has been instituted in Paris, under efficient auspices, the Protective Society of Infancy.

Medical Degrees for Women in Great Britain.—A bill to amend the medical act as far as it relates to the registration of women who have taken the degree of doctor of medicine in a foreign University, is now before the British Legislature. The present law refuses to recognize men as practitioners of medicine who are not possessed of British qualifications, but it is proposed to make exceptions to this in favor of females. On this subject, the London *Lancet* truly says: "If certain foreign boards of examination are to be recognized as competent to say what persons are fit to practise medicine in this country, it is absurd to restrict the recognition of their competency to the case of females only. The Legislature would surely not commit itself to so silly an enactment as that of two persons, one a female and the other a male, possessed of foreign degrees, the female should be admitted to the Medical Register, and the male should not. This would be a curious way of remedying the partiality of past legislation. It is not by such measures that the doctrine of the equality of the sexes is to be promoted."

Weston's Pedestrian Feats are attracting considerable attention in London with scientific men. Among others Mr. Ashburton Thompson, of that city, has been keeping account of his condition, with a view of a full report of the case, and Dr. Pavy, of Guy's Hospital, has been more particularly engaged on the analysis of the urine, with a similar object in view.

Alumni Association of the Miami Medical College, Cincinnati, Ohio.—The regular annual reunion of the Alumni Association of the above college took place February 28, 1876. The following officers were elected for the ensuing year:—*President*, Dr. B. Stanton, City; *Vice-Presidents*, Dr. R. C. Bond, Aurora, Ind.; Dr. T. S. Neal, Dayton, Ohio; Dr. J. D. Gatch, Laurensburg, Ind.; Dr. W. M. DeWitt, of Longview, Insane Asylum; Dr. F. R. Evans, Franklin, Ohio; Dr. S. L. Ensininger, Crawfordsville; *Secretary*, Dr. William Judkins. *Treasurer*, Dr. J. L. Cilley. *Ex-Committee*, Drs. Wm. B. Davis, A. D. Bender, and L. A. Shepard.

Dr. Thos. A. Neal, of Dayton, Ohio, Class of '54, was elected orator for the reunion of 1877.

The retiring President, Dr. W. T. Brown, in an eloquent and appropriate speech, addressed the association, and welcomed the graduates of '76. On behalf of the latter, Dr. Allison Maxwell made a fitting and a very happy response. The oration, *the* feature of the evening, was delivered by Dr. G. R. Patton, Class '55, of Lake City, Minn. His subject, the "Medical Pendulum," was handled in a very scholarly way. The usual toasts were responded to, and the affair was altogether a great success.

The City Mortality for the Past Year.—From the Report of the Board of Health for 1875, now in the course of preparation, we learn that the number of deaths for 1875, from all causes, in this city, was 30,709, which is an increase of 1,984 over the number reported for 1874. Of this number, 10,908 were from zymotic diseases, an increase of 1,106 as compared with the mortality from this cause for 1874. There were only 1,186 violent deaths reported for 1875, which was 62 less than during the previous year. There were 646 more deaths from diphtheria in 1875 than in 1874. There was also a considerable increase in the mortality of children under five years of age, as compared with that of 1874. Dr. Elisha Harris, the ex-Register of Vital Statistics, states in his report that for three years diphtheria has been adding largely to the mortality among the children in this city. Until recently there has been only a small amount of this disease south of Fourteenth street, and that has been chiefly confined to the Seventeenth Ward, the region of the old Stuyvesant meadows. In this ward, in 1873, there were 2,302 fatal cases of diphtheria; in 1874, 2,193, and in 1875, 2,486, in a population of 101,094. In the Nineteenth Ward the number of deaths from diphtheria was 13,589 for the three past years in a population of 117,835. In the Twenty-first Ward, including the Murray Hill district, in a population of 58,883, in the past three years, there were 6,284 deaths from diphtheria. Cleanliness and disinfection of the premises are recommended, and the isolation of cases as much as possible. In 1875, 3,352 children under five years of age died from diarrhœal diseases in this city. Great improvements have been made in the tenements, in consequence of which it is claimed that the poor of New York enjoy greater advantages than in the great European cities, particularly Berlin, Munich, Breslau, or Liverpool.

How to Preserve Leeches.—Dr. Andberg has given the results of his experiments on the preservation of leeches. He experimented by placing five unhealthy leeches in a glass jar half filled with water, and containing about an ounce of the common black oxide of manganese well pulverized. For the sake of comparison he also placed five healthy animals in another glass jar similarly prepared. Both jars were then exposed to strong daylight. After four or five days small bubbles began to rise from the bottom, and the diseased leeches began to present a more lively and healthy appearance. The water was not changed for three weeks, when it became necessary on account of the death of two of the animals. The remaining three continued well, and no further change of the water was necessary for many weeks. The other five leeches continued to remain healthy, though the water was not changed for eight weeks.

In another jar, prepared in the same way, he placed four leeches that had just been used. The water was changed in a few days, as the leeches had thrown off much blood, after which no further change was necessary for two months.

Dr. A. says that much time and expense may thus be saved in hospitals where leeches are extensively used. —*Usp. Läkareför. Förhandl.*, I.

THE DISCOVERY OF MODERN ANÆSTHESIA:—A CRITIQUE.

By H. P. STEARNS, M.D.,

HARTFORD, CONN.

Columbus conceived the idea, or received it from the records of voyages made by mariners before his time, that one, by sailing due west, would discover land. He accordingly acted upon this suggestion, left Spain on the 3d of August, 1492, and on the 12th October discovered one of the Bahama Islands.

To avoid references to authorities in the several portions of this paper when they might seem to be required, I will here remark, once for all, that every essential statement made has been substantiated by the sworn testimony of disinterested persons—holding the highest social positions in Hartford, as well as of physicians, clergymen, and lawyers—such evidence as would be deemed sufficient to vindicate claims in any of the courts of justice in this or other countries.

He afterwards made these voyages, discovering several islands and the main-land of the new continent, though not himself aware of the fact. Through the machinations of his enemies, he was sent home from the field of his discoveries in chains; and, finally, after suffering disgrace and the ingratitude of his king during seven weary years, he died in poverty and neglect; not even knowing, himself, that he had added a continent to the wealth of the world! During the latter part of his life, and for years after his death, others claimed the honor of his discoveries, and sought to reap the emoluments arising from them.

Jenner, when a student in medicine, heard from a young woman that she could not take small-pox, because she had already had cow-pox. This suggestion he never forgot; but not until 1796 did he actually make the test, and demonstrate it to be a fact, by vaccinating James Phipps. He immediately wrote to his friend Gardner, that he had at length accomplished what he had so long been waiting for; and with exultation declared that the boy had since been vaccinated for small-pox without success, as he had ventured to predict. After making other experiments (unfortunately we do not know how many) he went to London, to make known, more widely than before, his discovery. His reception was disheartening in the extreme. Not only did the doctors refuse to make trial of the process, but the discoverer was accused of an attempt to "bestialize" his species by introducing into their systems diseased matter from a cow's udder. He returned home, with surprise and chagrin, and afterwards published an account of seven (7) successful cases.

But it was not until about a year afterwards that his discovery began to be looked upon with any favor, and then it was brought about by one Mr. Cline, who had been successful in vaccinating some persons. Some of his medical brethren undertook to rob him of the honors of his discovery; and it was not until some three or four years after his first experiment that vaccination with vaccine from cows came to be accepted by the profession, and he honored as its discoverer.

Wells, on the 10th Dec., 1811, witnessed some experiments made with nitrous oxide, and saw one person while under its influence bruise himself severely. After the effects of the gas had passed away, he questioned this person as to his injuries, and learned, to his surprise, that he was unaware of any. He then made the suggestion to David Clarke that one could have a tooth extracted without pain while under the influence of that gas. The next day he took the gas, and had a molar tooth extracted without pain by his friend Riggs. During the next few weeks he tried the experiment upon fifteen (15) persons, extracting teeth in all cases without pain, except two. These thought they felt a little pain. Elated with his grand discovery, he started for Boston to make it known more widely than could be done in Hartford. He at once went to his former pupil, Dr. Morton, and to one or two surgeons, all of whom received his statements with much incredulity. After waiting several days, he succeeded in getting an opportunity to test his theory once, in the extraction of a tooth; but, as the bag containing the gas was removed too soon, the patient made some noise and shouted; and in consequence the audience of medical students hooted and hissed, and called the whole affair "*a humbug*."

Wells returned home annoyed and disappointed; and being of a sensitive nature, and in delicate health, was quite unwell for several months. He, however, continued to use the gas in his own offices when engaged in dentistry, or with his friend Riggs; and, during the succeeding two years, in as many as fifty (50) cases successfully. One of the surgeons of the city, Dr. Marcy, after a conference with Wells, in relation to the properties of sulphuric ether as compared with those of gas, used ether, and removed an encysted tumor without pain, while Wells was present. He encountered great obstacles in vindicating his claim as discoverer, because his former pupil, Dr. Morton, laid claim to the honor of discovery, in consequence of having succeeded with ether in 1846. Wells, having exhausted his slender resources, and stung by the treachery and ingratitude of one to whom he had revealed the steps to his discovery, both in respect of gas and ether, after nearly two years of effort to vindicate his claim, became insane and died.

The above three cases rest upon precisely the same kind of evidence, and have points of remarkable similarity. Each of the parties had a definite idea in his mind and announced it to others. The first, that by sailing due west from the southern portion of the European Continent, one would discover land. The second, that the system was so constituted that it would become insensible to the poison of small-pox, by first becoming vaccinated with cow-pox. The third, that the system was so constituted, that by inhaling enough nitrous oxide gas, it would become insensible to the pain of surgical operations.

Each of them succeeded in demonstrating that his idea was a truth, before any other person laid claim to having done so. Two of these parties found great difficulty in convincing the medical profession that they had made a discovery of incalculable value to the world. They all had rival claimants to the honor of discovery, and years passed before the completeness and full significance of their discoveries were understood.

There no longer exists any doubt as to whom the honor of discovery belongs in the first two cases; and the third is so similar, in all the essential points pertaining to a discovery, that a mere statement of the case, in conjunction with the others, would seem to be enough to place it beyond dispute.

And, since the American Medical Association, and other learned bodies, and men, both in this and other countries, have pronounced in favor of Wells as the rightful discoverer of modern anæsthesia, his friends

might well rest content, and let posterity do, as it has done in the other cases, award to each his rightful niche in the gallery of discoverers.

But the friends of one of the claimants, with a pertinacity as great as that shown by the Court of Spain in its efforts to detract from the honor of Columbus, still persists in keeping his case before the public, and in endeavoring to secure honors and emoluments which rightfully belong to another. In fact, our Boston friends, with a pardonable pride in matters of *scientific discovery*, not unfrequently formulate their convictions thus:—

"W. has shown this, and J. that; but it was reserved for our own M. to make the imperishable discovery. And it seems probable that the average Bostonian still believes that modern Anæsthesia was first discovered by inhaling ether."

Therefore it is a matter for special congratulation on the part of the friends of Wells, that this latest effort on behalf of Morton has been presented by no less a person than Professor Henry J. Bigelow, M. D., of Harvard University.* This is specially gratifying, because we may be sure, that one who has from the first been deeply interested in, and identified with, the ether claim, and has done far more for it than Morton himself, will be sure to present the case with learning, as well as every available argument in its favor. If, therefore, a critical examination of Dr. Bigelow's arguments shall eventuate in showing that they are unsound; that, in fact, they are wide of the subject he undertakes to discuss, pertaining to improvements since, rather than to the subject of discovery; and that Morton obtained his knowledge of anæsthesia from Wells, in the first instance, instead of by discovery; and that his work was a mere continuation of what Wells had already shown, and to be ranked with the labors of Sympson, Richardson, and others—I think we may let the case rest.

Let us therefore examine the views of Dr. Bigelow, in reference to Wells's claim, in the light of history, as shown in the two cases already presented. And that there may be no misunderstanding in the use of terms, it may be well to define two or three as preliminary.†

1st. A discovery is "the finding out or bringing to light something before unknown."

2d. "*An Anæsthetic* is an agent which produces anæsthesia by being received into the lungs in the form of vapor or gas, and passing with the blood to the nervous centres on which the action is exerted."

Examples: chloroform; sulph. ether; nitrous oxide; chloric ether.

Using these definitions, we find the discovery of modern anæsthesia to be the bringing to light or making known what was before unknown, viz., that the body can be rendered insensible to surgical pain by the inhalation of one of the above-named substances.

Did Wells conceive this idea and convert it into a certainty before Morton did? Dr. Bigelow admits his priority of inception, but denies that he demonstrated its truth. He considers that thirteen (13) cases of painless extraction of teeth were insufficient for this purpose—that the partial failure in rendering two of his first fifteen cases insensible vitiated his proof and rendered it inconclusive. Let us look a little more closely into this view of the subject. What did these two partial failures render inconclusive? Was it that the body could be rendered insensible to pain by breathing nitrous oxide? Certainly not! That must, in the nature of things, have been a fact since man and nitrous oxide have existed. Neither Wells, nor any one else created this fact. It is a fact now; it was a fact then; it has been such in all ages; and Wells, when he brought to light this fact on the 11th Dec. 1844, thereby became a discoverer. We now know, and he suspected, why he partially failed in those two cases. A few more inspirations of gas would have rendered them just as perfect as his other cases; and I fail to see how this circumstance affected in any way the essential fact.

Let us see how Jenner would have fared in Dr. Bigelow's review. When he had made but *one* successful vaccination, he proclaimed to his friends that he had demonstrated his prediction; and the date of that first successful vaccination has been celebrated ever since as the time of his discovery. Was it made then or afterwards? If afterwards, when? Was it with his second, or fifth, or seventh case? Jenner evidently thought it was with his first.

If, then, Jenner's discovery is universally conceded to have been when his first case proved successful, why not Wells's also? Wells no more needed fifteen or one hundred and fifty cases to make his a discovery, than Jenner.

Again, take the case of Columbus. When do we date the discovery of a new continent by him? Why on the day that he first descried that little island. The continent was not discovered, except prospectively, for years afterwards, or until his third voyage. This developed or grew out of the island discovery. Was it, therefore, any the less discovered? Or if Columbus had died previous to his third voyage, would he any the less have been entitled to the honor of having discovered a new continent?

Let us now refer to the question of *certainty*. Dr. Bigelow lays much stress upon the seeming failure of Wells in his experiment before the Medical Class in the Massachusetts Hospital. Does this failure (if it was one, which is by no means certain) in any way invalidate Wells's claims. I think not. The anæsthesia had been perfect in his former thirteen (13) cases. Dr. Bigelow admits that insensibility by nitrous oxide at the present time is "unfailing." Does a failure to secure it on one occasion affect the question at all? Would it do so now? If not now, why then?

Suppose Columbus had perished in his second voyage; on account of the unseaworthiness of his vessels; or for any other reason, had failed to reach the islands he had discovered during his first voyage, would this failure have, in any way, affected the fact of his discovery during his former voyage?

Or let us suppose that the first case in which ether was given in the Massachusetts Hospital, had been one, such as we are all familiar enough with now—a person of full plethoric habit and accustomed to the free use of stimulants; and, in consequence, that after ether had been given a few minutes, he had begun to shout and struggle, that his face had become livid, his eyes partially fixed, and he had exhibited symptoms of becoming asphyxiated. Let us suppose Morton to have been a stranger, with only one or two friends who really knew nothing about the effects of ether, or if anything, only enough to make them doubt as to its safety—that the audience was one of students, attracted by curiosity; under such circumstances, which we all know might have occurred, can we doubt there would have been shouts of derision, and, if the operator had continued, of denunciation and interference, long before etherization had become

* Dr. Bigelow's paper appeared in the January number of "The Journal of the Medical Sciences," with the title of "The Discovery of Modern Anæsthesia."

† This really becomes necessary, as there seems to be so much confusion in the mind of Dr. Bigelow with reference to the ordinary signification of terms.

complete? Yet it would simply have been a repetition of Wells's experiment, or rather worse, and signified nothing in reality as to the merits of the case.

Again, Dr. Bigelow says that Wells failed, because he did not show that anæsthesia by nitrous oxide was "*inevitable*." In another place, he admits that anæsthesia by nitrous oxide is now inevitable. If so now, why not then? Do facts in nature change? Hear his explanation—We now give a much larger dose!! Does he know how much Wells gave. We know he gave enough to produce anæsthesia in thirteen cases. He knew no reason why he should not do so in all cases. If, through inadvertence or mistake, he, or any one else, gave too little, twice or thrice, does it affect the fact of discovery? Would it have affected Jenner's discovery, if vaccinations had failed in three or four of the first fifty cases, through neglect to use fresh matter, or through its imperfect introduction? How often do we now fail for this very reason. There has never been a time when such failures have not occurred. Vaccination is not now, nor has it ever been as *inevitable* as anæsthesia by nitrous oxide.

Do we any the less honor Jenner as its discoverer?

Why, then, should Dr. Bigelow think that too small a dose in a few of the first cases of anæsthesia should render Wells's claim void? If now, after thirty years of experience, we found that only nine (9) out of ten (10) persons could be rendered insensible to pain by inhalation, anæsthesia would be still one of the most wonderful discoveries of the age, and of inestimable value to mankind.

Again Dr. Bigelow says, Wells failed because he did not prove that anæsthesia by nitrous oxide was "*safe*." Is it safe now? If now, it was then. Wells never found it otherwise. Was anæsthesia by ether safe during the first month of its use? Neither Dr. Morton or Dr. Bigelow knew that it was safe in the first case, or the first fifty cases. In fact, some time after it had been used in the hospital, Dr. Bigelow says Morton did not know in what the danger of using it consisted, but was on hand with a bag of oxygen. But, surely, we need not argue the question of safety, as we all must know that it has nothing whatever to do with the fact of discovery, but is merely an incidental. I very well remember hearing, when a medical student, Dr. Bigelow, while discussing the question of the safety of anæsthesia, say, that if it were certain one person out of a supposed number (I forget precisely the number, now) who should be rendered insensible by etherization, would die, still the discovery of anæsthesia would be one of inestimable value—that the risks should be taken as we take them in travel by railways and steamships. So much for Dr. Bigelow's three points which he considers essential to modern anæsthesia. They are all incidentals, merely; and, though important, as indicating the value of the discovery, yet, in the nature of the case, could only become known, long after both Wells and Morton made their claims.

It appears to have dawned on the mind of Morton after some years, that his claim could not rest on the fact of discovery, and in another part of Dr. Bigelow's paper the line of argument is changed. He says, "But Morton also urged that this was not a discovery in science, but in art; that surgical anæsthesia was due, not to any scientific novelty in the long recognized ether insensibility; but to his having worked out the application of this insensibility to use in art, with enterprise, and perseverance, through many details, in the midst of dangers, till he gave to the world a perfected system of efficient and safe anæsthesia. Morton was right again."

Let us analyse this view a little. Not a discovery in science, but in art; *i. e.*, the *manner* of administering ether! Neither Morton nor Dr. Bigelow took this view, when his claim was made, nor until years afterwards. They at first claimed that he had discovered a *fact*, and one of the most wonderful and useful ever brought to light in sciences. But finding, later, that they could not vindicate this claim, because Wells had proved his earlier discovery, they then try to make the *manner* of administering ether cover the whole ground.

If this view is correct, anæsthesia has been discovered every time any one has found an improved method of giving ether; or ascertained that it could be produced by chloroform, or chloric ether, or other anæsthetic. No one now gives ether in the same way in which Morton first gave it; the *modus operandi* has changed again and again. The great fact of modern anæsthesia lies back of any *manner* of producing it, and this it was which Wells discovered, when he demonstrated that the body could be rendered so insensible to pain that a nerve could be lacerated or torn and the person not know it. No person had ever done this before, or made any such claim. The argument as to *method*, if used by any one less eminent than Dr. Bigelow, would be deemed puerile by scientific men. We might as well say, that the discovery of America consisted in improving the art of navigation, because one could, by this improvement, reach the continent more *certainly* and *safely*!! or that the discoverer of a new planet is he who succeeds in so improving a telescope, or in making a better one, that a planet discovered two years before, could be more easily or certainly found again!!

Again. Does the working "out the application of this insensibility to use in art, with enterprise and perseverance, through many details, in the midst of dangers," rightly constitute Morton the discoverer of modern anæsthesia? I fail to see how it does.

The truth is, there has never been a great scientific truth discovered, concerning which there was not additional knowledge afterwards coming to light. Newton is supposed to have conceived the idea of the law of gravitation, when he saw the apple fall while sitting under the tree, and afterwards demonstrated the existence of such a law or condition; but how little did he at first comprehend the whole system in all its details and extent.

The Brothers Pinzon, with wonderful perseverance, and in the midst of great dangers, succeeded in making many discoveries additional to those of Columbus; and either they, or somebody else, first showed that Columbus had discovered a continent, instead of the confines of Asia. In fact, they and others did immensely more towards developing and bringing to light, and thereby rendering the discoveries of Columbus valuable, than Morton has ever done in relation to Wells's discovery. All this has not changed the verdicts of mankind, nor in any measure dimmed the honor of Columbus. Can it be possible that posterity will not render a like verdict for Wells?

Before proceeding further, I must refer to an effort by Dr. Bigelow in the first part of his paper to rank the results of Wells's labors with those of Sir Humphrey Davy. He says: "In 1844 Horace Wells appeared, exactly repeating the hypothesis Davy had pointed. Davy commenced it, and the scientific world knew it. Did Horace Wells convert into a certainty the probability of Davy? He did not."

Let us examine this proposition a little. As preliminary, however, we will refer to a remark of Dr. Bigelow, in his preface to the extract containing Davy's

suggestion. He says: "It is impossible to read the annexed statement without renewed amazement, that this great blessing to animal existence was distinctly offered to scientific men, and as distinctly rejected by them, for half a century. The great discovery was here clearly pointed out to every tyro in medicine and chemistry. It only remained for somebody to test this hypothesis, this guess, and to convert the guess into a certainty."

What "great blessing to animal existence" was so distinctly offered to scientific men by Davy? Was it an improved method of administering ether? Not exactly! What was it? Why that "as nitrous oxide in its extensive operations appears capable of destroying physical pain, it may probably be used with advantage during surgical operations." This is the suggestion, the guess. It has nothing whatever to do with *mode, safety* or *completeness*. Yet Dr. Bigelow says it only remained for somebody to test this guess, and convert it into a certainty. He here seems to have a correct idea as to what constitutes modern anæsthesia. He is now, however, dealing with Davy. Is anæsthesia one thing with him when discussing Davy's suggestion, and another when discussing what Wells did? It has this appearance.

But it only remains to test this "guess." Pray how shall it be done? How is it likely Davy would have done it? If he had been a dentist, very likely he would have drawn a tooth. If he had been a surgeon, he might have opened an abscess or amputated a finger. Either of these would have been a test, and if there had been no pain a very conclusive one; and he would very likely have said, as Jenner did after his first successful case of vaccination, that he had converted his prediction into a certainty. Do we think there would have remained any doubt in his mind if he had found the same result in a dozen cases? Would he not have been warranted in saying to the world, "I have tested my prediction, I have demonstrated its truth?" If he had done this, would Dr. Bigelow have questioned his conclusions, or denied him the honor of discovery to-day? His whole language indicates the contrary. Yet he says Wells did not apply the test to this guess. So far as I know, there is not the slightest reason for supposing that Wells had any knowledge of Davy's suggestion, or that he obtained it from any one. We have seen how he came to have it—and that, to test it, he lacerated the nerves of more than a dozen persons, and then went to Boston for the purpose of making known the results and using it in a case of amputation in the hospital. His failure in Boston was no greater than that of Jenner in London. He and his friends continued to use it till his death. And yet Dr. Bigelow says he left the knowledge of anæsthesia "just about where Davy left it half a century before." I do not believe a more unjust, harsh and illiberal statement has been made in the discussion of any question of discovery or science during the last half century.

During the whole anæsthetic controversy great stress has been laid on the fact that Wells, after his disappointment in Boston, in a measure left the practice of dentistry and engaged in other pursuits which furnished him a more active life. This has been magnified by Dr. Bigelow and others into a total abandonment of his discovery. His family and his professional friends have testified again and again that this was not true. Moreover, his widow now has the bags for holding the gas which she made for him in the year 1845, and she was making them from time to time because he wished to increase the doses in certain cases. His friend Riggs was using it during the same year, and now has the book containing the original entries of his charges. Dr. P. W. Ellsworth wrote to this effect a letter, which was published in the Boston *Medical and Surgical Journal* in 1845; so that the evidence is indisputable; and yet Dr. Bigelow, in this centennial article on the discovery of anæsthesia, is so partisan as to ignore this evidence and reiterate the old story.

Again, not only were Wells, Riggs, and others using nitrous oxide in Hartford during 1845, but Morton was thoroughly aware of the fact; and during that and the succeeding year came to Hartford on at least two occasions, and is known to have had conferences with Wells on the subject, and from him and Riggs learned the fact that ether as well as nitrous oxide had been used. This last interview was only a short time before he drew the tooth of Eben Frost, under the influence of ether, in Boston. Therefore, as the whole truth stands, it is as clear as the light of noon-day that Morton's experiments were simply a continuation of Wells's. In fact, Dr. Bigelow himself, when discussing the claims of Jackson and Morton, says, "There can be no question that Morton knew about ether." Here we see how he came to know about it. He learned from Wells how he had produced anæsthesia with nitrous oxide and ether, as Mr. Cline learned from Jenner how to produce vaccination. The pupils in both cases were the instruments through whom the discoveries were to become more largely known; but what a contrast in their after-conduct!

The letters of Drs. Morton and Wells, dated respectively Oct. 19th and 20th, 1846, are again brought forward by Dr. Bigelow, to prove that Wells had given up anæsthesia by nitrous oxide as worthless. Yet this letter proves nothing of the kind, as we readily perceive, when we understand the impression under which it was written. Morton, in his letter, misled Wells by a false statement. He claimed to have discovered a new "compound" which was vastly superior to Wells's gas or ether. Wells, with the difficulties attendant on manufacturing, keeping, and transporting gas, and the supposed danger of ether, thought Morton had hit upon something likely to obviate these difficulties, as was claimed; and with this impression wrote this letter of congratulation to his quondam friend, as was natural. By doing so, he had not the remotest thought of yielding his claim to the discovery of anæsthesia; and after his visit to Morton, in Boston, returned home, not a little surprised at Morton's claim; having ascertained to his own satisfaction that the "*compound*," or "*letheon*," as Morton called it, was simply ether, which he had already used; knowing the effects to be similar to those of nitrous oxide. We might as fairly expect Morton to have relinquished his claim, because the next year Simpson discovered the anæsthetic properties of chloroform, which does away so far with the disagreeable properties of ether, that it very nearly superseded the use of the latter everywhere outside of Boston for several years.

Did space permit, I should like to refer to other portions of Dr. Bigelow's paper, but it seems hardly necessary to do so; I must, however, again draw attention to the inconsistency appearing between the opening and closing of the article. The subject of his paper he announces as "*The discovery of Modern Anæsthesia*." He closes with an all hail to "The INVENTOR *of the* ART OF ANÆSTHESIA!"

Surely the learned Professor cannot have forgotten, or expect others to forget, the distinction between a *discoverer* and an *inventor*—a *discovery* and an *invention*. His exclamation sounds very much as it would, in speaking of the discoverer of America, "All

honor to the discoverer of the art of steam navigation!" Or of the discoverer of vaccination, "All honor to the discoverer of the *art of vaccinating with a quill, or a spring lancet!!*"

In closing, I think we may fairly formulate what has been done in modern anæsthesia as follows:

1st. In December, 1844, Wells made the suggestion and applied the test in his own person, by inhaling a large dose of nitrous oxide, and having a tooth extracted without pain. He and his friends in Hartford continued to perform painless operations with nitrous oxide (except once, when ether was used) until his death.

2d. In September, 1846, Morton, a former pupil of Wells's, aware of his discovery and repeating his experiments, extracted a tooth without pain, while the patient was under the influence of sulphuric ether. He afterwards introduced the practice of anæsthesia by ether into the Massachusetts Hospital, and from thence it became known to the world.

3d. In 1847, Simpson first introduced the practice of anæsthesia in Midwifery, thereby making known more widely its value. He also discovered the anæsthetic properties of chloroform, and, by his writings and teachings, very largely contributed to introducing the practice of anæsthesia to the world.

4th. Others have since discovered the anæsthetic properties of different vapors, which are more or less used in practice.

The friends of Horace Wells have no desire to detract from the merits of what has actually been done by Morton, or Jackson, or others, in the field of anæsthesia; nor, on the other hand, do they propose to have the great fact of its discovery and first introduction by him ignored or set aside without protest.

THE TREATMENT OF FRACTURED CLAVICLE.

By FRANKLIN STAPLES, M.D.,

WINONA, MINN.

To mention the subject of fractured clavicle and its treatment, is sufficient occasion for a reply that nothing new can be said upon the subject. It is nevertheless a wrong conclusion, though one which we have been too much inclined to adopt, that a thing to be valuable and worthy of our attention must be new.

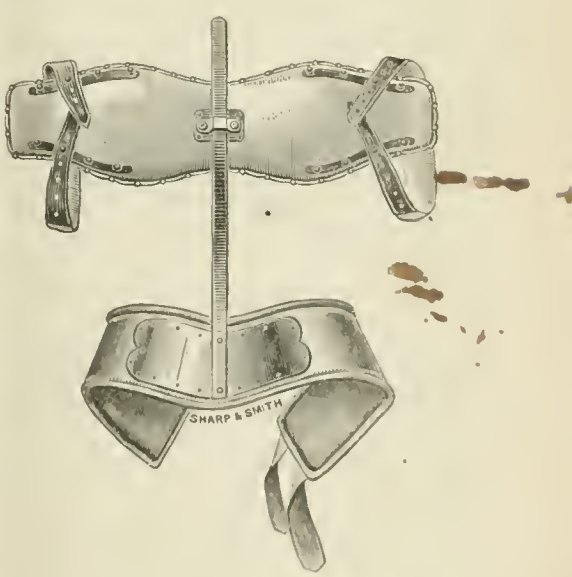
In the treatment which is here presented, it is only claimed that the more important principles of surgery, now fully established concerning this fracture in its more common forms, are met and complied with in a manner generally successful by a simple and convenient apparatus.

The more common fracture of the clavicle—and the one, whether in the child or adult, requiring efficient and careful treatment to avoid deformity, is known to be that generally produced by indirect violence—is usually in the middle third of the bone, is oblique, and presents itself oftener than otherwise with the inner fragment tilted upwards, and with the outer fragment tilted downwards and backwards. The deformity is from the overriding of these fragments with their relative positions as above; or where the fracture is incomplete, it is from an angular protuberance at the point of partial fracture. It is also true and well known that the displacement, especially of the outer fragment, is due to the weight of the arm and the mobility of the shoulder, it having now no bony support, together with the strong action of the muscles of the shoulder and thorax.

Treatment.—There are few cases of fractured clavicle with an overriding or angular deformity of the bone, in which the deformity will not disappear and the fragments fall into place, if the surgeon, standing behind the patient, with the latter in an erect, sitting, or standing position, will place his thumbs on the scapulæ of both sides and extend his fingers over the acromion processes; and thus, grasping the shoulder and pressing upon the scapula, draw the shoulders backward so as to cause the posterior borders of the scapulæ to approximate each other. And more especially will the displacement be found to disappear, if, while the shoulders are held in this fixed position, the arm of the injured side be brought directly against the side, and the shoulder relieved of its weight by a support placed under the elbow and forearm. Now, it is evident, and practical observation will demonstrate the fact, that if the scapulæ can be held thus fixed, the shoulders be kept thus immovable in their relation to the thorax, and the arm be kept thus supported, permanent extension will be maintained on the fractured bone, and in the recovery the least possible displacement and deformity will result.

The gliding of the scapulæ and shoulder, with its outer fragment of the clavicle, to some extent around the thorax, as around a cylinder, is the principal means of correcting the backward and downward tilting of the internal or fractured end of the outer fragment; while putting the whole bone upon a stretch, or at least relieving it of the exercise of its function as the brace of the shoulder, by supplying a permanent attachment for the shoulder behind, obviates the great tendency to displacement and deformity.

To serve the purposes above described, the apparatus represented in the accompanying cuts has been devised.



Five years ago a splint, in some respects similar to this, was presented by me to the Minnesota State Medical Society, and a description of the same published in the *North-western Medical and Surgical Journal*, and favorable mention of the same was made in the Report on Surgery by Dr. Marks, of Milwaukee, to the Wisconsin State Medical Society. The apparatus, as now presented, has been modified and improved, and is manufactured by Messrs. Sharp & Smith, of Chicago.

It has, of course, no patent, and can be improved by any surgeon having the requisite ingenuity. It consists of a curved and padded splint placed across the back on a line with the shoulder-joints. This not only presses firmly upon the scapulæ, but is so curved

as to fit upon the latter in such a manner as to hold them more firmly in a fixed position, both shoulders being brought back as much as may be required by means of stuffed bands attached to the splint at varying distances from the ends of the latter as the form and size of the patient may require. The splint is held in place by an adjustable upright slide of steel, slightly flexible and somewhat bent to the form of the spinal column, the lower end of which is firmly secured to a belt passing around the waist. The apparatus is light, quickly applied, adjustable to different sizes, and easily worn. It has no protuberances that prevent the patient from lying in bed upon the back. To complete the appliance, the usual handkerchief sling enveloping the elbow, supporting the forearm, passing over the opposite shoulder and fastened to the band there, is required.

Prof. F. H. Hamilton, in his treatise on *Fractures and Dislocations*, gives the names of Heister, Chelius, Miller, Keckerly, and others, who "prefer, for this purpose, some form of back splint extending from acromion to acromion, against which the shoulders may be properly secured." Dr. Parker says that splints of this kind, with a figure-of-8 bandage, are better than all other kinds of apparatus ever invented. The same principle is illustrated by the practice of compelling the patient to lie upon the back, with or without a pad between the shoulders, during the whole time required for the reunion of the bone. In this position the pressure from the weight of the chest firmly holds the scapula in position, while the shoulders, from their own weight, fall back into the same position as if bound to a splint. Although this cannot well be done in private practice, yet it was the treatment adopted by Dr. Buck, in the New York Hospital, and has the commendation of Drs. Post and Hamilton.

The splint of Keckerly, represented in the work of Hamilton, was faulty, and not likely to succeed in meeting the indications in any case, in that it was too narrow, without form to fit the back and shoulders, and not provided with suitable means to hold it firmly in position. The failure of this apparatus, and others of similar construction, to secure even the success of the apparatus of Fox, was not from error in principle, but rather from want of the proper application of the principle in the faulty and imperfect construction of the appliance.

The axillary pad is now generally ruled out of good surgical practice because of its uselessness and its liability to injure the nerves and vessels of the arm. Fox's apparatus has good points, but does not secure fixation of the scapulæ and shoulders, hence with its use deformity usually results.

The old trio of indications, "*backward*, *upward*, and *outward*," or rather the arbitrary attempts to meet them, have been productive of much mischief, and the usual want of success in securing good results in the treatment of this fracture has led to general dissatisfaction with all modes of treatment, and it has become quite fashionable among surgeons to adopt a kind of let-alone treatment, on the ground that more or less deformity is inevitable with any treatment. Moreover, it has been said that it is a matter of little consequence whether deformity results from a fractured clavicle or not. But I contend, that while it is far better to have a good result in all cases—for a perfect apposition, at least, favors a more rapid recovery—in some cases it is of the utmost importance to have as good a result as possible, this especially in the case of female patients. It is, then, important in this, as in all departments of medicine and surgery, to have within our knowledge and at our disposal at all times the best possible means of treatment.

THE EFFECT OF MEDICINES UPON THE TEETH.

By J. F. P. HODSON, D.D.S.,

NEW YORK.

It is an assertion very frequently made by patients to their dentist, in excuse for a largely decayed or much-filled set of teeth, or perhaps to account for their entire absence, that at such or such a time they had a severe illness, and that their physician had ruined their teeth with powerful medicines.* This is a very popular and deep-seated impression, and prevailing as it does among the most intelligent people, as well as those of other classes, it cannot be properly denominated a vulgar superstition or an ignorant prejudice, for the basal principle upon which they have built their pet theory is, alas, *very* true,—the teeth *have* decayed during the illness, and in some instances even more than during all the previous life taken together. I am persuaded, however, that as to the cause, the allegation is, in the great majority of cases, untrue,* and that the exhibition of acid remedies had comparatively little to do with the matter, and that this little may be reduced to a mere shadow by proper care. I hope to hereinafter show, as well as to offer some suggestions that may prove of service to the physician in warding off from the teeth of his helpless and practically unconscious patient, some of the terribly destructive influences which obtain during this period.

During the latter months of the period of gestation, and in fevers very especially, or the progress of

* It will be, of course, understood that reference is made in this article to substances which *decay* the teeth, and not to those which attack the alveolar and dental periosteums, as do the mercurial preparations.

any illness involving a feverish condition, the fluids of the mouth are constantly as intensely acid, as respects the teeth, as is any medicine administered by the physician; and, moreover, from the high temperature of the buccal cavity at such times, the power of these acids for evil is greatly augmented. Further, a direct consequence of these conditions is the especially rapid fermentation and decomposition of all food lodged between and around the teeth, and the consequent elimination of other deleterious acids,—all forming a mighty power, under which it is not surprising that tooth-structure should melt away like dew before the sun. It is indeed a *very* surprising thing that any tooth should live to tell the tale.

Still further, during such a period and condition of things—when of all times in one's life the mouth needs the best and most faithful care, it, in reality, because of the helplessness of the patient, receives *absolutely none*, and the teeth, poor victims, are left entirely at the mercy of this grand coalition of their enemies, who are all eager to advance their work of destruction, aye, complete it before they shall have again been brought to bay by the conditions of returning health and the tooth brush of the patient. And all this, forsooth, the physician's "powerful medicines" accomplish.

The physician is, however, the strong right arm upon which the patient should lean during illness, at least as to all things directly pertaining to it. To the physician, therefore, I appeal in behalf of all our mutual patients, that they may, by a few timely suggestions, looking to the neutralization of the acid condition then prevailing in the oral cavity, very essentially reduce the dreadful ravages of this period upon the teeth,—such, for instance, as directing the patient to rinse the mouth frequently with *liquor calcis*, diluted according to the sensitiveness of the mucous membrane, and flavored with a few drops of wintergreen or peppermint to make it agreeable; *or* to rub *creta prep.* freely about and between the teeth, and allow it to remain during the night; *or*, if the patient be able to use the tooth-brush, to add a small quantity of *sodæ bicarb.* to the usual tooth powder (for this purpose only, and not for general use); or, in short, the employment of any of the manifold methods of neutralizing the acid condition which may be most accessible at the time.

It may be objected to the foregoing that the mouth, during the progress of a fever, contains but little fluid of any kind; true, but this very circumstance makes the little which is there—the mucus principally—especially concentrated, and correspondingly baneful in its effects upon the teeth; whereas, in a normal condition of the system, the acidity of the mucus is entirely neutralized by the large influx of the alkaline saliva.

The tube through which acid remedies are usually directed to be taken *does not* prevent them from regurgitating upon the teeth in the act of swallowing, so that it practically accomplishes very little of the object sought to be attained by its employment; but if, in addition, the mouth be immediately and thoroughly rinsed with the solution of lime above referred to, or a solution of *sup. carb. sodæ*, the evil effects of any acid remedy upon the teeth will be entirely obviated.

In the exhibition of strong alkalies, on the other hand, which lay hold of the gelatinous constituents of the teeth, the fluids of the mouth during illness are, as has been stated, usually so pronouncedly acid as to entirely neutralize this condition; but if otherwise, a slight rinsing with a very dilute simple acid, like tartaric or citric, will accomplish the result desired, though the effect of these remedies upon the teeth is scarcely worthy of consideration, so entirely will the matter of their neutralization take care of itself. And even at other times than during actual illness is this the case with many of our people, who, with their irregularities, hot foods and drinks, the precipitate haste of their eating, and the half-masticated masses with which their stomachs are constantly insulted, are, even in health (?) much addicted to gastric disturbances, acid eructations, depraved and vitiated secretions, and a generally dyspeptic diathesis,—than which condition, by the way, none could be more inimical to the integrity of the dental structures.

Progress of Medical Science.

PARACENTESIS PERICARDII.—The following abstract is from a case presented to the Connecticut State Medical Society at its last session, by Dr. Irving W. Lyon, of Hartford, Conn.

A robust laborer, aged thirty-one years, was seized with pneumonia April 12th, 1874. The disease, which was confined to the right lower lobe, progressed favorably, so that resolution had commenced April 20th. On the 21st, the patient was seized with acute pain in the precordial region, auscultation of which gave the double friction sound of acute pericarditis. On May 5th, the patient was apparently dying; the area of cardiac dulness was greatly increased; the precordial region had notably bulged; head, face, and neck, very livid and swollen, and the entire body œdematous; pulse feeble and irregular, respiration labored. The vertical diameter of the liver on the mammary line was seven and one-half inches; resolution in the right lower lobe complete; every part of the left thorax yielded exaggerated resonance upon percussion, except that occupied by the distended pericardium.

The operation was performed by introducing a small trocar and canula through the fifth intercostal space, exactly three inches from the median line, and one inch to the right of the left nipple; the point was directed upwards and backwards, with an inclination towards the median line. The instrument entered just two inches, and upon withdrawing the trocar, pus flowed freely until thirty-two ounces were collected. The relief was immediate and marked, so that the patient was removed, in the space of a few moments, from a state of impending death to one of comparative safety and comfort. Six hours after the operation the pulse was 104 and regular, cyanosis nearly absent, and the liver dulness had diminished from seven and one-half to five and one-half inches. Twenty-two hours after the operation the pulse was 96, respiration 20, temperature 98⅘°, and the liver measured but four and one-half inches on the mammary line.

May 7th, two days after the operation, the former symptoms began to re-appear, and the patient gradually lost ground till May 12th, when it was determined to repeat the tapping. This was done in the same manner as before, but only one ounce and a half of pus flowed away, though all present felt confident that the pericardium contained much more. The patient died May 14th, having lived, after the first operation, nine days. No autopsy could be obtained. The trocar and canula were used because the contact of the heart with the aspirator needle, as the fluid subsided, was dreaded.—*Medical Communications of the Connecticut Medical Society*, 1875.

On the Origin and Spread of Carcinoma in the Female Pelvis.—Prof. Freund, of Breslau, believes he has found in the histories and autopsies of four cases, which he reports, new facts bearing upon the history and origin of malignant tumors. Whereas in married women of normal conformation the vaginal portion of the cervix uteri is subject to irritation, not to say injury, in coitus, in the cases of cancer he reports, such possible causes were, for one reason or another, absent. Thus the first case was in a *virgo intacta* of twenty-three, in whom a primary colloid cancer of the rectum extended through the connective tissue to the base of the right broad ligament and cervix uteri, death resulting from peritonitis from perforation. The second case was in a virgin of forty, in whom a villous medullary cancer, which began in the posterior wall of the bladder, gradually involved the anterior vaginal wall, the connective tissue on the left side of the pelvis, the left ureter, and finally occasioned deposits in the outermost layers of the left half of the cervix. In the third and fourth cases, owing to a constriction of the upper portion of the vagina, the cervix being protected, remained free from cancer, although the vaginal walls, and secondarily the rectum, were involved in the disease. These cases, he thinks, suggest the importance of thorough exploration in cases of obstinate catarrhs, or difficulties of excretion in the pelvic organs.—*Virchow's Archiv*, Bd. 64.—*Berlin. Klin. Woch.*, Jan. 18, 1876.

Bouton de Biskra.—Dr. H. Vandyke Carter read a paper before the Royal Medical and Chirurgical Society on this disease, as it occurred at Biskra in 1874. One-third of the soldiers, and more than one-half of the officers of the battalion, were afflicted with the disease. The "bouton" resembles the Delhi boil, so well-known in India, and has been compared with the Aleppo evil. A few days after its appearance, the "bouton" is found to be composed almost entirely of a granulation-tissue. But in addition he found a true parasitic organism, consisting of spheroids and mycelium, which occupied the distended lymphatic vessels in and around the "bouton." At a subsequent stage of the "bouton" these vegetable organisms seemed to disappear, and there were found besides pale, round and stellate granulation cells, numerous bright, orange-tinted particles, which were arranged as spherical or ovoid groups, everywhere disseminated throughout the tissues of the tumor. By microscopic scrutiny, the endemic limitation of the bouton de Biskra, its seasonable occurrence, incubation period, and limited duration, its multiplicity of local manifestation and non-recurrence, and its inoculability, were all satisfactorily explained on the supposition of the parasitic origin of the affection. In the after discussion, Dr. Tilbury Fox said he had examined two preparations of the "bouton" sent over by Dr. Carter, and had failed to detect the existence of any parasitic elements. In the deeper parts of the tissue, appearances like mycelium could be seen, but they seemed rather to resemble ordinary lymphatic tissue. There was very little question as to the inoculability of these affections. Dr. Thin was inclined to believe the disease was in a great degree syphilitic.—*The Lancet*, February 12, 1876.

Mania-a-potu.—Dr. L. A. Dugas, in a paper read before the Medical Association of Georgia, relates his treatment of this disease. It consists of the administration, once or twice a day, of cold water affusions, of such food as may be relished, and at times of two or three small glasses of toddy. If the patient is very unruly, one or two intelligent persons should attend him day and night, as long as it may be necessary. For the affusions, the patient should be stripped of all garments and seated in a tub, the physician should pour one pitcherful after another over the head in a regular stream, which will pass down over the entire body. The affusion is to be continued from one to three minutes by the watch. The pulse, at first full and strong, soon becomes small and frequent. The physician should watch this carefully, and cease whenever the patient is entirely rational and the pulse sufficiently subdued. After the patient is rubbed and dried, and the room darkened, he will generally sleep six or eight hours, and awake perfectly rational. With the exception of toddy, all narcotics are eschewed in the management of the case.

Anchylosis of both Elbow-joints.—At a meeting of the Medical Society of London, Mr. William Adams brought forward a case of this kind, where there had been anchylosis of both arms in the extended position, the result of rheumatic fever three years before. The treatment of the left arm proved successful by subcutaneous division of the shaft of the humerus just above the condyles, after which the forearm was flexed to a right angle, and placed in a rectangular splint. A fortnight subsequently, passive motion was commenced and steadily continued. Forcible extension was used in the right arm, which the left arm resisted,—therefore the subcutaneous division. Mr. Adams referred to the pathology of rheumatic anchylosis, observing that such cases were most favorable for the operation of forcible movement under chloroform, in consequence of the absence of any destructive disease in the articulation. This was the first case where subcutaneous division of the humerus had been performed.—*The Lancet*, February 12, 1876.

Mammitis and Mammary Abscess Treated by Bandaging.—Dr. L. A. Dugas read a paper before the Medical Association of Georgia upon this mode of treatment. To lessen the determination of blood to the mammæ while inflamed, the child is to be suckled as seldom as possible, and gentle compression sufficient to force out the blood from the distended vessels, and cool applications to the organ are the proper remedies. He has devised a bandage which, he believes, combines all the requisites. It consists of cotton or linen shirting, about ten inches wide, and long enough to surround the thorax, and to be secured in front by digitations, similar to other "many-tailed" bandages. This is to be applied from the axilla down, pass around the chest and over the mamma, and be tied in front of the sternum. It effectually compresses both organs, and can be loosened or tightened without any difficulty. The child may be nursed through an aperture for the nipple made in the bandage. As soon as the congestion becomes painful or threatening, the bandage should be applied with such moderate tightness as will relieve pain, and the treatment should be continued until the trouble has entirely subsided. When suppuration takes place, the pus should be let out by the free use of the bistoury, and a linen tent renewed daily. There should also be an opening in the bandage opposite the incision for the escape of pus. This bandage is adapted to every stage of mammary inflammation. If too late to prevent suppuration, it will lessen the size of the abscess, and after an opening has been made for the escape of pus, it will bring together the walls of the abscess and hasten the cure. One of its greatest advantages is that it relieves the patient of all pain as soon as it is applied, by removing the distension to which the unsupported tissues are subjected by the congestion, or the accumulation of pus.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

PUBLISHED BY

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, April 1, 1876.

SHORTENING THE TIME OF STUDY.

To any one who has taken the pains to follow the discussion regarding the relative merits of the different medical colleges at Louisville, the hope of reform in matters of medical education seems a long way off. In the ardor of defending the claims of their respective institutions, the editors of the *Louisville Medical News* and the *American Medical Weekly* are disclosing some rather refreshing facts for the contemplation of the uninitiated.

In Louisville, containing as it does three medical colleges, it is quite natural that a spirited struggle for preferment should be engendered, and that a considerable difference of opinion should exist between them in regard to the adoption of the best means for securing the largest classes and obtaining the most money. This is all well enough, and gives evidence of that commendable desire to aid in educational reforms which is so prevalent in other cities having the same facilities. One of the privileges of every medical school in this country is to claim that it is better than its neighbor, and that it deserves to succeed while the other merits ignominious failure. This is what is usually termed a generous rivalry, and the institution which makes the greatest pretensions and is loudest in its self-praise appeals the strongest to the sympathies of outsiders. If schools have medical organs, so much the sooner can this desirable end be accomplished, provided there is no one to dispute their claims. This is the trouble in Louisville; and it seems so difficult to settle which of the colleges is the best that the journals in question are discussing the matter with more ardor than discretion. The result has been that they have torn each other's drop-curtains, and the audience is allowed a glance of the sham stage machinery behind.

Evidently compelled, for the sake of success in obtaining classes, to meet the requirements of popular demand for short courses, small fees, and cheap diplomas, each school is striving to outdo the other in smoothing the road to graduation. The result of such endeavors can easily be foreseen. The limit of this medical auctioneering must be reached some time or other, and may in the end result as did the famous fight between the cats of Kilkenny. In the meantime each combatant is doing his best to injure the other,—scratch for scratch, blow for blow, and howl for howl. If one college gives two full courses in one year, the other does worse; if one grants beneficiary degrees, the other cheapens its instruction in another guise, and so the fight waxes hot. As far as we can see at this distance, neither one of the colleges is entitled to the countenance and support of the profession of that part of the country, and in fact the necessity for their existence at all, under their present respective managements, is a question which every impartial medical man has a right to consider. If the facts stated by either side are true, there is a system of corruption in the matter of medical teaching there which is melancholy to contemplate. We have not noticed any defence for the yearly two-course system; in fact it is virtually admitted in attempting to justify the course pursued by a reference to similar doings elsewhere. In regard to this particular phase of the question Dr. Gaillard, the editor of the *American Medical Weekly*, says:

"And now for the question of two courses of lectures in one year. Any student in any medical college in this country can go to the Long Island College or one of the Cincinnati colleges in March, and enter upon his second course of lectures; graduating in June of that year; that is in nine months. A good student can do this at these colleges, and also at the University of Virginia. This is well known, or ought to be well known to every journalist in the land. The colleges named are in full affiliation with all municipal, county, and State medical societies, and with the National Medical Association. But these facts are not the facts which suit the partisan purposes of those who have partisan objects to accomplish or personal spleen to gratify. Indeed, a Cincinnati Medical College has for years given and now gives two graduating courses in one year. The Atlanta Medical College has done the same thing."

If this be true, and we see no reason to doubt it, it is high time that the profession looked this matter fairly in the face; it is high time that this monstrous evil should be in some way remedied. What hope can there be for reform in medical education if the system of corruption in so-called high places is allowed to go on, not only unchecked but unrebuked.

THE INTERNATIONAL CONGRESS OF OPHTHALMOLOGY.

SOME twenty years ago, in the city of Brussels, a number of practitioners of medicine who were working specially in a department which the invention of the

ophthalmoscope had brought into great scientific prominence, organized what is called the "International Periodic Congress of Ophthalmology," a body which has held sessions every four years. It met first, as we have said, in Brussels; then in Paris on two occasions; and finally, in 1872, in London. The objects of this organization, as stated by its rules, are "to promote ophthalmological science, and to serve as a centre to those who cultivate it."

The sessions of the society take place every fourth year, and they have usually lasted for about three days. Many of the men most eminent in ophthalmic science have contributed papers and taken part in the discussions at the meetings, so that the volumes of transactions have a permanent value. At the meeting held in London in 1872, there were eleven delegates present from the United States—from Boston, New York, Philadelphia, Rochester, St. Louis and Davenport. The Boston and New York delegations invited the Congress to hold its next session in America; and, after a rather spirited discussion, New York was selected over Madrid. The Philadelphians, not then fully alive, perhaps, to the glory awaiting that city in Centennial year, made no offer of it for a place of meeting of the Congress. Since then, as was seen by the last number of this journal, the International Medical Congress to meet in that city has arranged for a section to be devoted to Ophthalmology, but this must not be confounded with this Congress. The New York committee appointed in London, have nearly perfected their arrangements for the meeting of the Congress of Ophthalmology. It will assemble at Chickering Hall on Tuesday, September 13th, at 12 o'clock noon.

A committee will be in attendance, on the Monday afternoon and evening previous, to enroll members of the Congress and candidates for membership. The American Ophthalmological Society will entertain the foreign guests, together with distinguished members of the general profession, on Thursday evening, Sept. 14, at Delmonico's, and there will be various receptions for the delegates. Professor Helmholtz is expected to visit America, expressly to be present at the Congress, with others nearly as well known. Communications are constantly being received from the old world, showing that the sea-passage does not deter some of our foreign brethren from their usual visit to this Congress when held nearer home. Inasmuch as the discussions of this body take in all of optical science, it is believed that all our eminent physiologists and physicists, as well as the ophthalmologists, will be glad to enrol themselves as members of a Congress which only prescribes that its candidates for membership shall be "either a doctor of medicine, or of surgery, or of science, or possess some other equivalent degree, or be distinguished for scientific knowledge."

The profession in New York, as well as our educated classes, will certainly cordially welcome the assembling of an International Scientific Congress, which is the first to appoint a meeting in the United States.

THE DISCOVERY OF ANÆSTHESIA.

The vexed question concerning the discovery of Anaesthesia being again before the professional public, Dr. H. P. Stearns, of Hartford, contributes, in the present number, a very interesting article upon the subject. Every one who has, during the past ten years, taken the pains to examine the validity of the respective claims of Wells, Morton and Jackson, must be surprised at the stand taken by Dr. Bigelow, and must applaud Dr. Stearns in his praiseworthy efforts to turn the current of opinion in its proper direction. There can be no doubt that Wells was the real discoverer of anæsthesia in its present accepted signification; and that to him, and to him alone, belongs the credit of conferring this priceless boon upon humanity. Dr. Stearns founds his statements upon fact, and the conclusions at which he arrives, based as they are upon sound argument, must carry conviction to the mind of every impartial reader.

MEDICAL ADVERTISING.

The correspondent who favors us with a communication concerning the Medical papers recently presented to the Public Health Association, very properly rebukes the action of their authors as an "abuse of privilege." There is no doubt that the Association is capable of doing a great amount of good in advancing Sanitary Science, and we wish it God speed; but its object can never be attained so long as medical advertising is an incentive for much of the work that is done. It is quite necessary that medical men should be members of such an organization, as they are eminently fitted to offer counsel on all subjects pertaining to preventive medicine. Their duties in that respect can always be satisfactorily performed without the slightest violation of the Code. Teaching the public is one thing, but medical advertising is another. Our correspondent very generously gives them the credit of unintentional wrong, and out of courtesy to such charity we shall not take issue with him.

Reviews and Notices of Books.

Phthisis: Its Morbid Anatomy, Etiology, &c. By Austin Flint, M.D. H. C. Lea. 1875.

Dr. Flint is one of the very few original writers on medicine of whom this country can boast. He neither translates, compiles, nor abstracts from foreign authors. All of his published works have been characterized by the same merit:—a careful study and analysis of cases of disease observed by himself.

In the present work he gives us the results of his observations of phthisis. The study embraces an analysis of 670 cases of this disease. From these cases he deduces conclusions concerning the morbid an-

atomy, the etiology, the symptoms, the fatality and prognosis, the treatment, and the physical signs and diagnosis of phthisis. From the insufficient character of his records, however, only a moderate number of cases can be used for the study of each of these different topics.

We must confess that our feeling, after reading the book, was of regret that Dr. Flint should have sacrificed so much labor for such unsatisfactory results. It is easy to appreciate the patience and the time which must have been consumed in comparing and analyzing so large a number of cases. And yet, as the result of all this time, labor, and patience, what do we find? hardly a single new fact.

While, then, we must thank Dr. Flint for adding to our collection of facts on the subject of phthisis, we must regret that so much good work should be of so little value.

ADDISON'S DISEASE. By EDWARD HEADLAM GREENHOW, M.D., F.R.C.S. Philadelphia: LINDSAY & BLAKISTON.

FROM time to time a monograph will appear on some medical subject, which is so complete, so exhaustive, and so lucid, that for many years all discussion is closed, and the monograph becomes the standard authority on that particular topic. Such is the character of this treatise on Addison's Disease by Dr. Greenhow. It exhausts our present knowledge of the subject. For the next five years at least it will be our authority for all that concerns Addison's Disease.

ON SPERMATORRHŒA: Its Pathology, Results, and Complications. By J. L. MILTON, Surgeon to St. John's Hospital for Diseases of the Skin. Tenth edition. London: ROBERT HARDWICK, 192 Piccadilly. 1875.

IN many respects Dr. Milton's treatise upon this subject is worthy of commendation. Although it is evidently the work of an enthusiast, using the word in the sense in which it is more commonly employed, yet there is sufficient evidence of true enthusiasm to convince the unprejudiced reader that its merits more than balance its demerits. Dr. Milton takes the ground that spermatorrhœa is a disease, and not a mere symptom, as it has quite generally been regarded. "Even though it is nothing but a symptom," says the doctor, "the subject merits all the attention he has given it," and it is quite probable that this is true. The author "rejoices that the battle of spermatorrhœa has virtually been fought and won," and in the present edition of his book the vigor with which he strikes his gatlings into some of his antagonists indicates that he is determined to have his clarion notes heard in triumph.

ILLUSTRATIONS OF CLINICAL SURGERY. (Part II.) By JONATHAN HUTCHINSON, F.R.C.S.

ATLAS OF SKIN DISEASES. (Parts II.—V.) By TILBURY FOX, M.D. Philadelphia: LINDSAY & BLAKISTON. Second notice.

HUTCHINSON'S illustrations include varieties of soft venereal sores, balanitis, melanosis, hydrocele of the neck, and two anomalous unnamed affections of the skin. The plates are excellent, both in the matter of selection and in artistic execution. The letter-press which accompanies them is particularly instructive, and contains many new and original views. With reference to soft venereal sores (chancroids) H. believes that they "are due to the contagion of the pus produced by syphilitic inflammation," and the hard (indurated) chancres "to that of the specific virus of syphilis. The pus acts almost immediately after its implantation, whilst the virus requires an interval before its effects can be recognized. Either may be implanted alone, or both together, and if the latter happens, then a sore which was for the first month quite definitely soft may at length take on induration." It is doubtful if this proposition will at present gain any very general acceptance, although to the mind of the writer there undoubtedly exists a much closer connection between the hard and soft sores than the professed dualist would be disposed to admit. What this connection is, it would be a little hazardous to assert. It is one of the problems which the future may perhaps solve.

FOX'S plates are of the same character as those already noticed, and illustrate strophulus, roseola, lichen, eczema, and impetigo. The text which accompanies them is in the main judicious and instructive, but the nomenclature is Willanic in the extreme; and, however useful in its day, must at the present time be considered as unphilosophical and perplexing, and calculated to hinder rather than increase a diffusion of sound knowledge concerning cutaneous affections.

Correspondence.

MEDICATED SPRAY TO GENITO-URINARY TRACT.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—In your journal of March 18th, Dr. Edson has an article, in answer to a communication of mine, on "The Application of Medicated Spray to the Genito-Urinary Tract."

The doctor, inadvertently, I presume, leads the profession to infer that I claim to have *invented* the Spray instrument; while the fact is, I explicitly state that the instrument I am using is the "*ordinary one*, with the addition of the long arm," &c.

He next calls attention to the illustration, and attacks the engraver for representing the Spray as "flying freely in all directions, and for some distance from the nozzle, indicating that the Spray, *as such*, impinges on the mucous membrane. Had Dr. Edson read my article *carefully*, he would not have made that criticism. I said, that "by the use of this instrument we are enabled to reach every part of the uterine cavity, and bring our medicated substances to bear directly on the mucous membrane."

It will be seen that the point which the doctor attempts to make in reference to "Spray *as such*," is purely at the expense of *the engraver*, and of minor importance.

I now repeat, for the benefit of the doctor, that our medicated fluids are brought in contact with the mucous membrane in such finely divided particles, as to reach the cavities of the womb, vagina and bladder completely, without shock; and the results of such treatment are eminently satisfactory.

Before calling attention to some well-known facts to sustain me in the above statement, I beg leave to protest against the habit in some of criticizing a matter of experience, a fact of practice, on purely theoretical grounds. How can a gentleman who "has had no experience" judge of the value of a fact which must of necessity, be founded almost entirely upon

experiment? The doctrine I maintain is, that in the investigation of morbid action, the physician has *nothing to do* with "preconceived notions." His mind must be free from bias. His convictions derived from an honest and intelligent exercise of judgment in each particular case which presents itself. The treatment of disease deals with pathological, not physiological conditions. However much the walls of the womb may be closed in the natural state, in a diseased condition more or less of a cavity exists; in cases of physometra, for instance, when the womb sometimes becomes *very much* distended with gas. Women lying on the back, with the womb gravitating into the hollow of the sacrum, will have air enter the vagina, pass up into the *cavity* of the womb, and be expelled on a change of position. Again, we know that injections thrown into the vagina have been known to pass through the cervical canal into the cavity of the womb and through the Fallopian tubes. Lastly, we are aware that the process of involution, following delivery, is often imperfect, leaving the walls of the womb flabby and not contracted upon themselves; which fact proves, beyond question or doubt, that there are certain diseased conditions of the womb which would easily admit of applications being made by means of the Spray instrument. For the sake of argument, admitting Dr. Elson's theories "that the cavities of the the womb, bladder and vagina, are always closed," the walls certainly are not *glued together*, (this is a pathological condition not *often* met with, as far as my experience goes,) and they can be separated by the introduction of any instrument. Without doubt, the larger the calibre the larger the cavity.

Now, if my friend will place his patient on her back, introduce any speculum he is in the habit of using, exposing to view the os externum; then, as soon as he is satisfied that the cervical canal is large enough to admit the tube easily, and allow free motion, let him pass the tube to the *fundus*, and, as he gradually withdraws it, let him work the hand-ball. He will succeed in throwing the fluid, finely mixed with air, into the *cavity of the womb*.

In withdrawing the instrument we will notice air and water escaping into the speculum, and since *no solid can occupy the same space at the same time with a fluid*, this in itself should convince him that there must at times be an open cavity in the womb, and demonstrate to him that the practical application of the spray is "as beautiful as the theory." He will have the satisfaction of seeing "the mechanical impediment" he speaks of disappear, and it will leave him with the comforting reflection that "his old-fashioned notions" have been considerably damaged.

E. Bradley, M.D.

TREATMENT OF DIPHTHERIA.

To the Editor of the Medical Record.

Sir:—Thanking you for your generally accurate report of my paper on Diphtheria, read before the Academy of Medicine, permit me to encroach on your space for the correction of a typographical error or two.

First and most important: instead of an ounce and a half of tincture of iron in the first prescription, the formula given was as follows:

℞ Tinct. ferri perchloridi. ..... fl ʒ jss
Glycerini,
Aquæ, āā..... ʒ j
M

The direction accompanying this prescription, and the following one is, "a teaspoonful to be given *every hour*," (not every two hours,) so that the two shall alternate at half-hour intervals. When the Salicylic Acid mixture is used, it is *instead* of the second prescription, not in addition to it. The total recoveries, out of 124 dispensary patients, was 94.

The quantity of glycerine in the third prescription, is, of course, ℥ss, not ʒ ss.

Yours very respectfully,

C. E. Billington.

A PLEA FOR EXACT BIRTH REGISTRATION.

To the Editor of The Medical Record.

Dear Sir:—Notwithstanding the earnest efforts of the "Department of Vital Statistics" to obtain an accurate record of births occurring in this city, it must be conceded that many physicians neglect the important means of accomplishing it, perhaps not wilfully, but from the present inconvenience, or forgetfulness, much to the disappointment of the department and to their own risk of penalty for the omission. I consider it a matter so intimately connected with the interests of the profession and of society, that we should all take a pride in its perfect fulfilment.

My own method has been to obtain the requisite information from some member of the family before leaving the house, rather than trust to the chance of procuring it subsequently. Whilst it may be objected that the record places the names of the new-comer and parent in a rather miscellaneous group, we may console ourselves with the thought that the inevitable "death record" has no rose-scented, gilt-edge page for millionaires different from that for the less-favored ones of fortune; so that in this, at least, we must all yield alike to the great leveller of our race. Some parties, married late in life, thinking it an impertinent inquiry, may be fastidious about giving their ages, but when informed of the possible future importance of the record for identity, etc., will usually be found to accede with a good grace.

It has always been my plan to enter in a day-book the *hour of birth*, and I propose to show incidentally what I consider may be its necessity in a legal point of view, by a possibility in a case at present within my own knowledge. A youth was left a legacy in trust, payable when he attains a certain age; supposing his birth to have occurred in the evening, the payment to be made in the morning of the day he reaches the required age, of the money disbursed at once by him in previous obligations, and death should overtake him before the hour shown by the birth-record, would not the trustee probably be held liable by the heirs of the young man for any deficiency in the sum thus paid? I think he would, but I may be in error. Again, it occurred to me to have been called on by a guardian to inquire the age of his ward (about to be married), who had asserted her right to the care of her large fortune, and also wished to dispense with further payment of commissions on it. As he had expected to have continued his office one year longer, he was evidently quite disappointed when I told him, on referring to my journal, that the young lady was entirely correct in regard to her age.

I presume that such instances might be multiplied

in the experience of others of the profession; but my object will have been accomplished, if I shall, by this brief statement, only awaken the interest of its members in a much neglected duty.

As somewhat germane to the subject, the following paragraph from this morning's newspaper is added:

"John Stevens, of Logansport, Ind., was heir to $12,000, and at his earnest solicitation the money was given to him when he was only nineteen years old. He has squandered it all, and now sues the trustees to make them pay him over again, his claim being that they should have held the property until he was twenty-one." K.

New York, March 13, 1876.

GLAZED BRICK IN HOSPITAL CONSTRUCTION.

To the Editor of The Medical Record.

Dear Sir:—I have read with interest your recent articles on "Hospital Construction," etc., and am glad to find that the subject is commanding increased attention from some of the most intelligent of our profession.

Nevertheless, the best system of hospital construction yet devised is far from perfect.

The vexed and vital question of drainage is still in an unsettled and unsatisfactory state, and no material yet suggested for interior walls fully meets all the requirements.

In addition to iron, stone, corrugated glass, glazed tiles, etc., suggested by various writers, it has occurred to me that an article of glazed *brick* could be made, that might be found nearly if not quite impermeable to moisture, and suitable for exterior as well as interior walls. Many of the difficulties attending the subject of drainage would not exist if, in the selection of sites for hospitals, this subject received all the consideration it is entitled to. In my opinion, no large, permanent hospital should be located within the thickly populated portions of cities.

In these days of railroads and steamboats, and consequent "rapid transit," all large or permanent hospitals should, if possible, be located outside of the city limits, at some point where all the topographic and and hygienic indications are best fulfilled.

At no distant day the withdrawal of the sick from crowded cities, and their location at points and under conditions most favorable to their recovery will be looked upon as a fundamental rule of hospital hygiene. Respectfully, etc.,

C. B., M.D.

St. Paul, Minn.

CLINICAL STATISTICS OF AN EPIDEMIC OF SCARLET FEVER.

To the Editor of The Medical Record.

Dear Sir:—In The Medical Record of November 20th, 1875, you published a record of the inception of an epidemic of scarlatina which has been in progress in my practice since October last. I have taken notes of seventy-five cases from the number occurring, which directly came to my notice. In fifty of these cases the initial symptom was vomiting—occurring in these fifty cases within the first twenty four hours of the first noted indisposition. In all the cases which proved fatal, vomiting was a persistent symptom.

In twenty five cases the affection of the throat was severe. In these twenty-five cases the only sequelæ which occurred was adenitis, which in some of the patients went on to suppuration. It is worthy of mention here that all of the cases in which a strong liniment of camphorated oil was thoroughly used, the termination was by resolution and not by formation of abscess. In the cases in which adenitis appeared, I discovered no affection of the kidney, no albuminuria, and no œdema, though I examined carefully for them in each case.

The complication of albuminuria and œdema occurred in fifteen cases noted; of these eight could be directly traced either to exposure at too early a period or to particular errors in diet; the other seven showed no complication whatever, save the disease itself. Convulsions occurred in six cases; two at the maximum of the eruption; both of these cases were fatal; four appeared about the eighteenth day. These were speedily controlled by the free use of bromide of potassium, except in one case which had convulsions quite frequently for nearly a week. In this case, a child of eleven years, the pupils were largely dilated, and, I think, the child was blind for the same period. On alternating the bromide with iodide of potassium, the improvement was marked, and convalescence soon occurred. In two cases, abscess of the tonsils appeared within the first five days, simultaneous with the irruption. These cases did perfectly well and recovered without sequelæ.

The shortest duration of any case noted was ten days; the longest, including sequelæ, fifty-five days.

Number of fatal cases, four; of these two died before the fifth day; one on the eleventh day, and one on the eighteenth day. Three of these cases were under the age of eight years, and one had reached the age of twenty-four years, which last had the complication of a diphtheritic exudation in the throat, which came off on the eighth day in the form of membrane, tough and of yellowish white appearance.

The case which was fatal on the eighteenth day had high fever and vomiting from the commencement. The fever was continuous from first to last, not at any time noted to fall below 104 F., nor above 106° F. Quinine was not tolerated by the stomach, and cold affusion was interdicted by the parents, so we had the benefit of neither.

In one case, in the person of my own child, the temperature rose to 107°; rash was purple, and child exceedingly restless; vomited often, and violently delirious. On the third day cold ablution was used, sponging with cold water eight times in one night. After the first bath, child slept one-half hour; awoke restless and delirious; another bath used, slept an hour; the other six used during the night with equally good effect. The baths were used, but not as frequently for the next three days, when desquamation occurred and child made a rapid recovery. The other remedies used in the case were carbonate ammonia and ammonio-citrate of iron, as recommended in Smith's Diseases of Children.

Of the seventy-five cases the respective ages appear thus: *Two* below *one* year; between one and three years, none; between three and six years, thirty five cases; between six and ten years, fifteen cases; between ten and fourteen, seven cases; over fourteen and under thirty years of age, sixteen cases.

David Dana Spear, M.D.

Freeport, Me., *February* 28, 1876.

MEDICAL ESSAYS BEFORE THE PUBLIC HEALTH ASSOCIATION.

To the Editor of the Medical Record.

Sir:—The comments in your issue of March 18th, on what you term "medical advertising," are no doubt based upon a fair and correct interpretation of the code of Medical Ethics. I would remind you, however, and through you, the medical profession, that the Public Health Association of New York is not a medical society. The plan and purpose of its organization had in view the establishment of a society to be composed of persons "selected with especial reference to their acknowledged interest in, or devotion to, sanitary studies and allied sciences, and to the practical application of the same." Consequently, the membership includes gentlemen representing various professions, as well as a number of merchants. It was never intended to be a medical society, and the presentation before it of such papers as those you criticise, in an abuse of privilege which should call for more vigilance on the part of the Executive Committee.

The attendance of reporters at the meetings, by invitation, originated in a desire on the part of the association to disseminate useful knowledge, which should prepare the way for public sanitary reforms. The society, as a body, has never given any encouragement to strictly technical medical discussion, beyond tolerating it with an easy good nature which has been fatal to its usefulness. I think the medical gentlemen who have read papers, and taken part in discussion, upon subjects of strictly professional interest, have in no case intentionally violated either the letter or the spirit of the code. They have merely—and without knowing it—made the mistake of bringing before a society organized for a specific work, matters foreign to its purpose, and, strictly speaking, "out of order."

It is to be hoped that the plan of reorganizing the work of the association, adopted at a recent meeting, will guard against such mistakes in future.

Lay Member.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department United States Army, from March 19th to March 25th, 1876.

Webster, W., Surgeon—Leave of absence extended 20 days. S. O. 49, Military Division of the Atlantic, March 18, 1876.

Meacham, F., Assistant Surgeon—Granted leave of absence for one month. S. O. 56, A. G. O., March 21, 1876.

Hospital Statistics.—The annual report to the Commissioner of Charities and Correction, made by Dr Daniel H. Kitchen, chief of staff of the Charity, Fever, Epileptic, and other hospitals on Blackwell's Island, contains the following statistics, with others: Remaining in the hospitals on Jan. 1, 1875, 388 males and 359 females; admitted during the year, 5,282 males and 4,046 females; discharged recovered, 3,035 males and 2,401 females; improved, 1,561 males and 1,138 females; unimproved, 235 males and 198 females; died, 464 males and 307 females—making a total of discharged patients of both sexes, 9,271; remaining at the end of the year, 435 males and 369 females.

Medical Items and News.

Contagious Diseases in New York.—Through the kindness of Dr. W. De F. Day, Sanitary Superintendent, we shall hereafter be able to present our readers with a weekly tabulated Statement of Contagious Diseases reported to the Sanitary Bureau:—

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-Spinal Meningitis.	Measles.	Diphtheria.	Small-pox.
March 18th.....	0	4	83	6	51	128	48
" 25th.....	0	7	70	3	62	71	28

Woman's Hospital, N. Y.—Prof. Fordyce Barker was, at a stated meeting of the Board of Governors of this institution, unanimously elected as one of the attending surgeons, to fill the vacancy created by the resignation of Dr. Sims. This election was the result of a unanimous recommendation of the Board of Lady Supervisors and of the Medical Board. Dr. Barker was previously connected with the institution as consulting physician.

Dr. James Warburton Begbie, the distinguished Scotch scholar and physician, died in Edinburgh, his native city, Feb. 25, of cardiac disease, aged 49 years.

Diplomas of Dead Men.—A correspondent in a recent number of the *Medical Times and Gazette* (London, March 4) asks what becomes of the diplomas of deceased physicians. He doubts not that the great majority of these documents are preserved by the survivors, but he believes that some escape this care, and find their way upon the diploma market.

Spontaneous Rabies.—Mr. Fleming, in a recent number of the *Veterinary Journal* (London) reports a case which bears somewhat upon the spontaneous origin of rabies. A retriever dog, which had always been carefully tended, and was never out alone, was on but one occasion attacked by another dog, healthy at the time and since, and in the course of a month afterwards was seized with all the symptoms of hydrophobia, and was killed. While suffering from the disease the retriever bit three other dogs, one of which was seized with "dumb madness," and was eventually killed. The original biter is still alive and well, but under observation. No one doubts Mr. Fleming's ability to diagnosticate hydrophobia, but it is barely possible that the retriever dog may have been bitten by an actually rabid animal, the fact being unknown even to his watchful master.

Scurvy in the British Marine.—Within the past half year the British mercantile marine has been accredited with more than seventy cases of scurvy. The causes of the occurrence are said to be insufficient anti-scorbutics and bad beef.

A new Clinical Thermometer, the index of which is coated with glass to prevent erasure, is manufac-

tured in London. This is a very desirable improvement, and should be adopted in this country.

Death from Septic Inoculation.—The *London Lancet* (March 4) mentions a case of a woman, "a layer-out," in the Isle of Man, who died as the result of inoculation. She was called to lay out the body of a person who had died of gangrenous erysipelas of the arm. The woman, having pricked her finger with a thorn, hesitated, but ultimately undertook the duty. Subsequently she showed symptoms of blood-poisoning, which ended in her death.

Muscular Exertion as a Cause of Albuminuria. Mr. Benj. Duke, writing to the London *Lancet*, says: "When a student at Guy's I entered for the mile race in the United Hospital Sports. Two days previous to the race I ran a mile. The same evening, happening to be reading a work on the urine, describing how to test the same, I thought, by way of illustration, to test my own. My horror may be imagined on finding it to be nearly solid with albumen. I did not feel ill at the time, and it disappeared within twenty-four hours. The next day but one previous to the race I tested my urine, and found it healthy, and again ran a mile, and on examining some urine passed immediately after, found it nearly solid with albumen, which again totally disappeared in about twenty-four hours, and may therefore be fairly attributed to exercise; for it is now nearly nine years since I have found any."

Prof. Frank Hawthorn, of University of Louisiana, New Orleans, died of Bright's disease, Feb. 24, 1876. He was born in Conecuh Co., Alabama, Sept. 20, 1835, graduated in medicine at medical department of University of New York in 1859, and during the war served as surgeon in the Confederate army. In 1866, he was appointed Prof. of Chemistry in the New Orleans school of medicine; in 1869 he was elected to a full professorship of clinical medicine in the University of Louisiana; and in 1874, he exchanged this chair for the one of diseases of women and children, which he held at the time of his death.

A New Convalescent Hospital.—The elegant hotel at West Point, known as Cozzens', was recently purchased on foreclosure by a lady of this city, who presented it to the Society of the N. Y. Hospital to be used as a home for convalescents. The governors of the hospital are taking immediate steps to adapt the building to its new purposes. Convalescents from the St. Luke's Hospital are also entitled to its privileges.

The Pay of Army Surgeons.—The bill to reduce the salaries in the army, provides that the pay of assistant surgeons shall be $1,500 per annum, and that of the full surgeon (major) $2,500.

Dr. Charles F. Rodenstein, of Tremont, N. Y., died March 10, 1876, from pneumonia. He was a graduate of the College of Physicians and Surgeons, Class of 1867, was Sanitary Inspector of the Board of Health, and a respected and successful practitioner. The following actions were taken by the respective associations of which he was a member.—At a meeting of the corps of Sanitary and Assistant Sanitary Inspectors, held at the Headquarters of the Health Department, Monday, March 10th, 1876, the following resolutions were unanimously adopted:

Whereas, It has pleased an all-wise Providence to remove from our midst our late friend Dr. C. F. Rodenstein, one who has endeared himself to us all by his many traits of kindness, geniality and manly worth, therefore, be it

Resolved, That, in the death of our associate, we have lost a true friend and earnest fellow-worker, whose example we emulate and whose memory we cherish.

Resolved, That a copy of of these resolutions be sent to the family of the deceased, as an evidence of our sincere sympathy, and another published in the Medical Record.

Wm. De F. Day, M. D., *Chairman.*
Allan McLane Hamilton, M. D., *Secretary.*

—At a meeting of the Yonkers' Medical Association, the following resolutions were adopted:

Whereas, Death has removed from our midst one of our most valued members and Ex-President, Dr. Charles F. Rodenstein, therefore, be it

Resolved, That in the death of Dr. Rodenstein, we mourn the loss of a valued brother, a true-hearted noble man, a skilful physician, and a devoted student of medical science.

Resolved, That we tender to the family and friends of our departed brother our heartfelt sympathy in this dark hour of their affliction.

Resolved, That we attend the funeral of Dr. Rodenstein, from his late residence at Tremont, in a body.

Resolved, That a copy of these resolutions be sent to the family of Dr. Rodenstein, and also published in the Medical Record, the *New York Medical Journal*, and the local newspapers.

Committee: J. Foster Jenkins, M.D., J. H. Pooley, Sr., M.D., E. Peugnet, M.D.

March 19th, 1876.

—At a meeting of the New York Obstetrical Society, held March, 21st, 1876, the following resolutions were adopted relative to the death of its late Fellow, Dr. Charles F. Rodenstein, of Tremont, N. Y.:

Whereas, This Society has learned with deep regret the death of Dr. Charles F. Rodenstein, therefore be it

Resolved, That this Society recognize in the late Dr. Rodenstein an active and invaluable Fellow, whose regular attendance at its meetings, costing him a journey of many miles, was a proof of his professional zeal and constant interest in the welfare of the Society.

Resolved, That the death of Dr. Rodenstein is a loss to the profession, of an able and energetic physician, and to society of a gentleman of large culture and genial disposition.

Resolved, That the Society tender to the bereaved family of Dr. Rodenstein their heartfelt sympathy in their affliction.

Resolved, That a copy of these resolutions be sent to the medical journals of this city for publication.

Committee: John Byrne, M.D., James F. Hunter, M.D., Charles S. Ward, M.D.

T. Gaillard Thomas, M.D., *President.*
Paul F. Munde, M.D., *Secretary.*

American Medical Association.—The twenty-seventh annual session will be held in the city of Philadelphia, Pa., on Tuesday, June 6, 1876, at 11 A.M. The delegates shall receive their appointment from permanently organized State Medical Societies, and such County and District Medical Societies as are recognized by *representation in their respective State Societies*, and from the Medical Department of the Army and Navy of the United States. Each State,

County, and District Medical Society entitled to representation shall have the privilege of sending to the Association one delegate for every ten of its regular resident members, and one for every additional fraction of more than half that number; *Provided*, however, that the number of delegates for any particular state, territory, county, city, or town shall not exceed the ratio of one in ten of the resident physicians who may have signed the Code of Ethics of the Association."

Secretaries of Medical Societies as above designated are earnestly requested to forward, *at once*, lists of their delegates, in order that the Committee of Arrangements may be enabled to form some idea of the number likely to be present.

Sections.—"The Chairman of the several sections shall prepare and read in the general sessions of the Association, papers on the advances and discoveries of the past year in the branches of science included in their respective sessions. * * "—By-Laws, Art. II., Section 4.

Practice of Medicine, Materia Medica, and Physiology: Dr. Francis G. Smith, Philadelphia, Pa., Chairman; Dr. B. A. Vaughan, Columbus, Miss., Secretary. Committee appointed to report to this section—On Clinical Observations: Dr. N. S. Davis, Ill., Chairman, Dr. H. A. Johnson, Ill., Dr. J. B. Johnson, Mo. Obstetrics and Diseases of Women and Children: Dr. S. C. Busey, Washington, D. C., Chairman, Dr. Robert Battey, Atlanta, Ga., Secretary. Committee appointed to report to this section—On the connection of the Hepatic Circulation with Uterine Hyperæmias, Fluxions, and Inflammations: Dr. L. F. Warner, Mass. Surgery and Anatomy: Dr. Alonzo Garcelon, Lewiston, Me., Chairman, Dr. E. T. Easley, Dallas, Texas, Secretary. Medical Jurisprudence, Chemistry, and Psychology: Dr. E. Lloyd Howard, Baltimore, Md., Chairman, Dr. V. L. Hurlbut, Chicago, Ill., Secretary. State Medicine and Public Hygiene: Dr. R. C. Kedzie, Lansing, Mich., Chairman, Dr. Ezra M. Hunt, Metuchen, N. J., Secretary. Committee to report to this section—On Form of Bill to establish a National Department of Public Health at Washington: Dr. H. B. Baker, Mich., Chairman, Dr. H. A. Johnson, Ill., Dr. M. Toner, D. C.

Papers appropriate to the several sections, in order to secure consideration and action, must be sent to the secretary of the appropriate section at least one month before the meeting which is to act upon them. It shall be the duty of the secretary to whom such papers are sent, to examine them with care, and, with the advice of the chairman of his section, to determine the time and order of their presentation, and give due notice of the same. * * * *"—*By-Laws*, Art. II., Sect. 5.

The following Committees are expected to report:—

On Mechanism of Accommodation of the Eye, Dr. D. S. Reynolds, Ky., Chairman; On New Remedies, Dr. Austin Flint, Jr., N. Y., Chairman; On the Medical and Surgical Uses of the Aspirator, Dr. E. S. Gaillard, Ky., Chairman; On Influence of Climate on Pulmonary Diseases in Minnesota, Dr. Franklin Staples, Minn., Chairman; On the same in Colorado, Dr Chas. Denison, Col., Chairman; On the same in Florida, Dr. E. T. Sabal, Fla., Chairman; On Proper Legislation to Prevent the Spread of Syphilis, Dr. Samuel D. Gross, Pa., Chairman; On Prize Essays; Dr. Samuel D. Gross, Pa., Chairman; On Necrology, Dr. S. C. Chew, Md., Chairman; On Rank of Medical Corps in the Army, Dr. H. A. Johnson, Ill., Chairmam.

W. B. Atkinson,
Permanent Secretary.

Periodical International Medical Congress.—The fifth session of this Congress will be held at Geneva in 1877. A committee of organization has been appointed by the medical society of the canton of Geneva, to act in concert with the scientific section of the National Genevese Institute. This committee is as follows: President, Professor C. Vogt; Vice President, Dr. Cl. Lombard; General Secretary, Dr. Prevost; Assistant Secretaries, Drs. D'Espine and Reverdin; Members, Professor Mayor, Drs. Dunant, Figuière, Julliard fils and Révilliod. The Congress will be exclusively scientific; it will last one week, commencing on Sunday, September 9, 1877. The official language will be French. All communications, whether in reference to the Congress or to questions which may be the subject of discussion, will be acknowledged by the committee. Such communications should be made before June 1st, 1876, at which time the committee will make their final decision as to rules and programme, and will appoint reporters. The Congress will open under the auspices of the Swiss Federal Council and the authorities of the canton, and of the city of Geneva. N.B.—All communications relating to the Congress, should be addressed to the General Secretary, Dr. Prevost, Geneva.

The International Congress of Ophthalmology will meet at Chickering Hall, Fifth Avenue, New York City, on Tuesday, September 12, 1876, at twelve o'clock noon. The following extracts from the rules of the Congress will give an idea of the general character of the Society, and of the terms of membership:

"1. The object of the International Periodic Congress of Ophthalmology is to promote ophthalmological science, and to serve as a centre to those who cultivate it. It will entertain no discussion foreign to this object.

"2. The number of members is unlimited.

"3. Every member must be either a doctor of medicine, or of surgery, or of science, or possess some other equivalent degree, or be distinguished for his scientific knowledge.

"4. Candidates for admission into the Society shall be admitted on presentation of their diploma or of their scientific title, unless ten members demand a ballot.

"5. The sessions of the Society shall take place every fourth year, and be limited to ten days.

* * * * * *

"XI. The Society gives no diploma. Before the opening of each session a card available for admission to all the meetings, and signed by the President and Secretary, shall be given to each member on payment of his subscription (fixed at $2), and upon signature of his name on the register of those attending the meeting."

ON THE TREATMENT OF ELEPHANTIASIS, WITH A TABLE OF FIFTY CASES.

By D. W. OSGOOD, M.D.,

SURGEON-IN-CHARGE OF FOOCHOW MEDICAL MISSIONARY HOSPITAL, FOOCHOW, CHINA.

Elephantiasis Arabum, Barbadoes leg, or maladie glandulaire, etc., are names given to various forms of skin diseases; but should be confined to that form of disease characterized by hypertrophy of the fibrous and intra-cutaneous tissues, and which, in a large majority of cases, is associated with enlarged lymphatic glands. Elephantiasis is comparatively common in the West Indies, in India, and in Southern China, while it occasionally occurs in Europe and the United States. The disease seems to show a partiality for the legs and scrotum. About three-fourths of the patients treated at Foochow have had the disease located in the legs, and the remaining fourth in the scrotum.

The usual history given by the patient is, "He had an ague fit or chill; and at that time, or a few days subsequently, he had enlargement of the part, accompanied by redness and pain, with swelling of the lymphatic glands." The ague may continue for months, or in exceptional cases there may be only one chill, at the time of the commencement of the attack.

Nearly all the patients have a sallow jaundiced look, are poorly nourished and come from malarious districts. In the early stages of the disease there is pain, swelling, and more or less of œdema. As the part enlarges, there is anæsthesia, and in some few cases ulceration. When the scrotum is involved, there may be constant pain, caused by the diseased mass dragging down and elongating the spermatic cords.

The size attained by these tumors varies from a few ozs., to one hundred and sixty lbs., the latter being the weight of a scrotum in the museum at Montpelier, preserved by Delpech. 3. A friend of the writer when in Formosa, saw a native whose scrotum extended to within six inches of the ground when he was standing erect. He utilized it by making it serve him as a chair, and it had the advantage of always being near at hand.

Passing to the treatment of elephantiasis, we may remark that internal medication avails nothing, except as the patient's general health is improved. With the latter object in view, quinine and iron may be advantageously administered in a large majority of cases. When the disease is recent, and located in the legs, we may hope for marked improvement, if not a complete cure. The leg should be carefully bandaged from the toes to the groin, and the patient confined to a horizontal position. Blisters should be applied over the enlarged glands in the femoral space; and it is a question worthy of careful consideration whether in some cases the enlarged glands ought not to be extirpated, thereby removing pressure from the deep veins and lymphatics. The bandaging should be continued until the leg regains its normal size, after which the patient should use a good elastic stocking when standing or walking.

With regard to the treatment of elephantiasis scroti we can speak with confidence, as over sixty cases have been operated on in China within the last fifteen years, and all have recovered, without a single exception. We know of no other capital operation which gives the same degree of relief to the patient, with as little risk, as that of amputation of the scrotum.

It may be asked, if the operation is as free from danger as represented, how is it that Liston and Key each lost his patient on the operating-table? And how is it that one of our best American authorities writes: *"If I had to deal with such a case, I should be tempted to cut away the mass piecemeal at several sittings, tying the vessels as they are divided, and using the actual cautery, to scar, if necessary, the raw surface. Or, instead of this, removal might be effected partly by the knife and partly by the écraseur."

We reply, that the principal danger to be apprehended is from excessive hemorrhage; and fortunately we have it in our power to arrest, or at least control it, by the use of Fayrer's tourniquet.

To show the necessity of some such appliance, we quote a few lines from the *American Journal of the Medical Sciences, No. CXXXIX.*, in which Prof. Neill records his experience in operating upon a case of elephantiasis. He writes: "Every incision was followed by free hemorrhage. There was great difficulty in securing the vessels, as they were dilated, tortuous and thin, and the structure in which they were imbedded was so dense that it was impossible to draw them out with the tenaculum. The veins were large sinews, and as the dissection progressed it became necessary to secure the bleeding orifices by needles and with ligatures. The operation was completed after four hours of most arduous labor." I am certain the danger or difficulty attending the operation, when performed without Fayrer's tourniquet, have not been overrated by the above-mentioned surgeons. The first case operated upon in the Missionary Hospital was for a scrotum measuring twenty-two inches in circumference, estimated weight twenty pounds. The operation required nearly two hours for its completion, and the hemorrhage was fearful, and we experienced the same difficulty in securing the bleeding vessels as Prof. Neill. In all our subsequent operations we have used Fayrer's tourniquet, and the hemorrhage has been trifling in amount.

Our usual method of operating may be conveniently described in connection with the history of case No. 5. The patient, aged thirty-four (34) years, presented himself for treatment with a scrotum measuring thirty-six inches in circumference. It had an unusually broad base, and came nearly to a level with the knees when the patient was standing. It was covered with verruncular growths, the largest of which were about the size of a pea, and together with the remains of an hypertrophied prepuce on its anterior surface, the growth presented all the usual appearances in such cases.

About an hour before the operation, the scrotum was elevated and compressed, so as to partially empty it of its venous blood. The patient being well under the influence of an anæsthetic, Fayrer's tourniquet† was applied about the neck of the tumor, and given in charge of two assistants, who were directed to make steady and firm traction. Two lateral flaps were dissected up, one from either side of the scrotum, the incision extending from the penis to within an inch of the anus. Next an incision was made through two inches of fibrous tissues, and one testicle dissected out from its abnormal covering; then the tissues anterior to and covering the penis were carefully divided upon

a director, until it was exposed to view. As the prepuce was diseased, it was entirely removed, and the penis dissected free from its surrounding adhesions; after which the remaining testicle was quickly found, and freed from the fibrous tissue in which it was imbedded. The genitals were given in charge of an assistant, who was directed to hold them well up out of the way, when the tourniquet was loosened and the tumor removed with a few strokes of the scalpel. An assistant, provided with a large sponge, was directed to make immediate pressure on the wound until the arteries could be ligated. In many instances torsion is quite sufficient to arrest the hemorrhage. The wound was dressed with carbolic acid solution, one part in forty, and afterward with a salve containing carbolic acid. It will be seen that the operation consists, I. In the elevation of the scrotum for an hour or more before the operation; II. The use of Fayrer's tourniquet. III. Dissecting up lateral flaps, which should not include any of the diseased skin; IV. Dissecting out the penis and testicles; V. Holding the genitals well out of the way, and removing the scrotum with a few well directed strokes of the scalpel; VI. Arresting the hemorrhage by pressing upon the wound and by ligating or twisting the arteries.

Should hydrocele exist, the sac should be opened with a free incision. In some cases the spermatic cords are much elongated, but they retract soon after the operation, and in a few days the testicles are drawn up close to the inguinal rings. The parts are usually covered with granulations in two or three weeks, after which time skin grafting may be advantageously resorted to. In conclusion, we append a table of fifty cases of elephantiasis scroti, which have been operated up in Southern China, all of which have recovered.

It will be seen by referring to the table that thirty-three of the patients had had ague. One had never had it, and in the remaining cases the record was defective in this respect. About one half of the patients have had hydrocele, and in connection with it the testicle has frequently been atrophied.

The average age of the patients has been thirty-eight, and the average duration of the disease eight and one-half years.

Case No. 4 we believe to be entirely unique. The tumor measured a foot in diameter and had its origin from the skin covering the linea alba and recti muscles. When the patient stood erect the tumor covered the genitals. As it gave him much inconvenience we decided to operate, but shortly before the appointed time the patient absconded, and we have heard nothing of him since.

Endocardial Vegetations in the Horse.—M. Trasbot, Professor in the Veterinary School of Alfort, presented to the *Académie de Médecin* recently, the heart of a colt aged eighteen months, which presented the following lesions; Chronic endocarditis with vegetations, and insufficience of the semilunar valves of the pulmonary artery; extensive dilatation, vegetation, and insufficience of the tricuspid valve.

M. Trasbot called attention to the following points in the history. When the colt was one year old, it was suddenly seized with marked lameness of the right leg, with red and painful swelling of the fetlock joint and pastern. This lameness lasted about three weeks, and was probably rheumatic in its nature. This was regarded as a new confirmation of the connection between rheumatism and diseases of the heart.—*Bulletin général de Thérapeutique*, February 29.

TWO CASES OF MUSCULAR RUPTURE IN WHICH MASSAGE WAS USED.

By DOUGLAS GRAHAM, M.D.,

of boston.

Case I.—Mr. J—— was a moderately corpulent, hale and hearty old gentleman, about seventy years of age. Nearly three years after rupturing the tendon of his left rectus femoris he called to see me, and I gathered from him the following history relative to his case: In getting off a horse-car, thinking it had stopped when it had not, he fell down, and as it was with difficulty he could stand when he got up, he was taken home in a carriage. The tissues above and around the left knee-joint were swollen and ecchymosed. As he bore with impatience the restraint of rest which his physician put him under, at the end of a week he attempted to walk, but falling down two or three times somewhat deterred him from further attempts at this means of locomotion. Immediately following this came a *merciful* (?) illness of gastric origin, which kept him in bed for a couple of weeks. At the end of this time the extravasation had been absorbed, leaving a depression above the patella, into which two fingers could almost be passed. Since then he had only been able to walk short distances, two or three squares or so, very awkwardly, and with his mind concentrated on the lame leg, for when he was off guard, which was quite frequently, he would fall.

About this time he consulted me, and after three applications of massage he walked from his house around the Common and Public Garden—about a mile and a half. The following week he had three more séances, when he again tried his pedestrian powers more than his business gave him any occasion to do, and this time extended his walk considerably beyond that of the previous week, "with greater ease and comfort," he said, "than he ever believed he would, and without scarcely thinking of the lame leg." After three more *massages* he went out of town to look at a country residence for the summer, and being seated in a rear car he thought they had not quite reached the depôt he wished to get out at. But when they started he discovered his mistake and pulled the bell-rope, got out when the cars stopped, and walked back to the depôt on the track, a distance of over a mile. The carriage he had engaged was, by that time, gone, and none could be got, for it was only a small country station. So off he started on foot and walked from and to the depôt, over a hilly country, in all about five or six miles, enough to tire almost any one, he thought, and yet the lame leg felt no worse than the other next day. He continued to have such good use of the limb without any more trouble for four months longer, when he was taken with a severe illness, which still keeps him prostrate.

The treatment was friction and kneading of the whole limb with the palm and fingers, varied with acto-passive or resisting movements of the foot, leg, and thigh in all their natural directions. While using the acto-passive motion it was interesting to observe from time to time the increasing strength and ease of movement which he was gaining. That such treatment often improves the nutrition and contractility and comfort of muscles, and consequently makes them more ready to obey the mandates of the will, or the automatic action of its subordinate centres, has been recognized from the most ancient times.

Case II.—Dr. Bull, of Worcester, has very kindly sent me his notes of the following case: Mrs. C., aged 45, a robust and muscular American lady, weighing 165 pounds, fell heavily on a slippery sidewalk, on March 13th, 1875. She did not bruise any particular part of her body, but made a violent effort to save herself, and was badly shaken. Her menses came on prematurely that day; * no other inconvenience was complained of, except a feeling as if she had taken cold in the neck. On the morrow there was decided pain in the neck and shoulder, which was not relieved by the usual household liniments, but grew steadily worse until I saw her on March 17th, four days after the fall. I found her carefully supporting the left elbow and hand, and inclining her head to the left side. When perfectly still, she felt only a dull ache; but the slightest movement of the head or arm caused her to cry out, with pain in the left shoulder, neck, and back of the head. The pain was distinctly cramp-like, and more severe than anything she had ever suffered, even in childbirth. The skin was not at all bruised, nor was there any signs of injury in the shoulder-joint. There was only great tenderness above the scapula, covering an area as large as one's hand. After half an hour's massage of the muscles of the neck and shoulder, the tenderness was found to be confined to a spot on the side of the neck, a couple of inches above the scapula, where the slightest pressure caused acute pain and spasmodic contraction of the anterior fibres of the trapezius, running up to the occiput two inches or so behind the ear. Light rubbing was soon tolerated over the spot, and the pain no longer radiated to the occiput and shoulder. Before leaving I was able to move the arm freely in all directions without causing pain, and the patient could move her arm and her head a little while my hand supported the trapezius, without the spasm coming on.

Diagnosis.—Rupture of anterior fibres of the trapezius, in the effort to save herself from falling.

The improvement continued, and the patient was tolerably comfortable lying on her right side. The spasm occurred occasionally in the night, and half a dozen times next day. There was thought to be a slight depression at the seat of pain, and a swelling behind it. On the 18th, after massage, the head could be raised and nodded, and moved to the right without spasm, but any attempt to move it to the left was followed by spasm, and was not persevered in. Massage was used by me for several days; voluntary motion of the trapezius was encouraged, and on the 31st of March all symptoms had disappeared. At present, August 4th, 1875, if the lady sweeps much or takes cold, she has some pain in the old spot, but rest soon relieves it. The doctor adds: "I have not given my notes in full, as they contain little else of interest; but I have said enough to show how a lady, not in the least nervous or hysterical, was relieved by *massage* of a very severe pain—restored to a healthy condition more speedily than could have been accomplished by any other therapeutic means."

Gently administered massage is soothing and hypnotic, hence its tolerance at the commencement of its use in this case. More forcibly applied, it is capable of producing an agreeable sort of anæsthesia,† so that by working at some distance from the painful spot, we can gradually approach it. The circulation at the same time being freely excited in the vessel and tissues near the cardiac side of the objective point, has a favorable revulsive effect. As soon as massage could be tolerated upon and about the seat of the injury, the effused products would be distributed over a greater area, their points of contact with the veins and lymphatic vessels increased, and, consequently, absorption—aided still further by the *vis-à-tergo* of the *massage* upon the returning circulation—could be carried on more rapidly; all of which, it seems to me, would be as likely to favor recovery in cases of this kind as in sprains.

These are the only two cases of the kind I know of. All the reading I can find about the matter is the following from Estradère, page 141: "In muscular rupture of small intensity, *le massage*, by favoring the resorption of effused liquids is one of the good therapeutic agents."

* A patient of mine, æt. 42, convalescing for a year from rheumatism, fell heavily on her nates, and the menses, which had been absent for three months, came on again.—(D. G.)

† A familiar example of this is the pinching up of the fold of skin between the thumb and forefinger, and working it for a minute or two before introducing the needle of the hypodermic syringe, which may then be done without the patient's even knowing the moment at which it penetrated the skin.

A CASE OF DISLOCATION OF THE RIGHT FEMUR ON THE PUBES.

By ERSKINE MASON, M.D.,

PROFESSOR OF CLINICAL SURGERY, MEDICAL DEPARTMENT OF THE UNIVERSITY OF THE CITY OF NEW YORK; SURGEON TO THE BELLEVUE AND ROOSEVELT HOSPITALS.

P. C., a strong muscular man, aged 55, was brought into my wards at Bellevue Hospital, Dec. 31, 1875, and gave the following history. On the evening previous to admission, while leaning against a railing which enclosed an area, in some manner, unknown to himself, he fell over the railing into the area, a distance of nine or ten feet. He was insensible when picked up (which was immediately after he fell); but on returning to consciousness he found he was unable to stand, and that there was great immobility of the right limb.

As the patient lay in bed the limbs were parallel, the right foot was strongly everted and fixed. He was unable to move the limb of his own accord beyond drawing up his knee to a slight extent. A globular prominence, which was evidently the head of the femur, was observed in the groin pushing upwards Poupart's ligament. By measurement, the head of the bone was found one inch from the anterior superior spinous process of the ilium, the femoral artery was pushed inwards and upwards, rendering its pulsations very apparent. He preferred to cross the sound limb over the injured one, as in this position he said he felt easier. The great trochanter was situated half an inch below and behind the anterior superior spinous process, and there was a marked depression in the normal situation of the trochanter. As he lay in bed, he could abduct the limb only to a slight degree. Two inches below the tuberosity of the right tibia was a recent abrasion of the skin. Upon making careful measurements of the limb from the anterior superior spinous process of the ilium to the end of the inner malleolus, I was surprised to find that the shortening was but a quarter of an inch. In order to be correct in these measurements I went over them several times, and they were all confirmed by Drs. Frank H. Hamilton and James R. Wood. Upon placing him in the erect position, he stood with the foot strongly everted, the heel slightly raised from the ground and resting just behind the inner malleolus of the sound limb, the knee a little flexed and thrown outwards. We could not bring the limb backwards or forwards, and could only abduct it slightly.

Patient being placed upon the floor and etherized, I proceeded to its reduction by manipulation. Present —Drs. Hamilton, Wood, the members of the house staff, and my class of students. The various manipulations that were resorted to are given in the order in which they were used.

First attempt. I slightly flexed the thigh, then made extension and rotated outwards, Dr. Hamilton at this period of the manipulation drawing upon the upper portion of the thigh by means of a jack towel in an outward and upward direction, while I brought the limb down to the floor. This attempt failed.

Second attempt. Flexing the thigh at a right angle to the pelvis and rotating outwards. This failed.

Third attempt. Flexion to same degree as before, and rotating inwards and bringing the thigh across the middle third of opposite thigh, pressing the knee down, at the same time making extension and bringing the limb down by the side of the other. Failed. During this manœuvre I felt the head of the bone slip, but upon examination it apparently had not changed its position.

Fourth attempt. Flexion to same degree as in the other two attempts, and making strong extension. Extension being made by a jack towel passing under the knee of the patient and over my shoulders, the pelvis of the patient being held down by means of a folded sheet passing over his pelvis and under the feet of two assistants, who stood on either side of the patient, the ends of the sheet being held securely in their hands (this device, which was suggested by Dr. Hamilton, answered admirably in holding the pelvis steadily to the floor). This attempt also failed.

Fifth attempt. Patient was turned upon his left side, and counter-extension made by means of a jack towel passing over the perineum, and held by assistants. I then, with the assistance of Dr. Wallace of the house staff, made extension from the leg and thigh, and after a moment or two of extension I pressed the thigh a little backwards behind the other, and the head of the bone glided into the acetabulum.

Patient was then placed in bed, where he remained for some two or three weeks, and left the hospital Jan. 25, 1876. He could walk without crutches, but preferred, he said, to rely on them a little longer.

I have regarded this case of sufficient interest for publication for several reasons: First, the position of the limb did not correspond to the usual description of this rare form of dislocation given in our text-books. There was not the marked abduction of the limb that is usually ascribed to this dislocation; on the contrary, the limbs were parallel, and it was with difficulty that any degree of abduction could be produced. With reference to the amount of shortening, it was less in this case than I should have expected or regarded before very careful measurements had been taken, and this point was particularly noticed by those who had the opportunity of examining the case.

With reference to the method which should be employed in the reduction of this form of hip dislocation, there would appear to be no fixed plan of procedure. Indeed, if we examine, as we have done, reported cases of this dislocation, we find that the methods that have been adopted and proved successful have been various. We are told, it is true, by Bigelow, that reduction may be effected in a variety of ways; and he describes, in his most excellent work on Dislocations of the Hip, no less than five or six methods of manipulation; though, as he states in his book, he has never met with this dislocation, we have no means of knowing which would be the most effectual. As far as we are aware, the only two dislocations of this kind that have been reduced by precisely the same manipulations are those occurring in the practice of Dr. Fountain, of Iowa, and reported in Hamilton's work on Fractures and Dislocations. Though in one of our attempts we employed almost the same kind of manipulation as did Dr. Fountain, we were unsuccessful; as were also other methods, which in other cases had proved successful.

From our study of this dislocation upon the cadaver, it would appear that this luxation should readily be reduced by flexion of the thigh, nearly if not quite to a right angle, then rotating the head of the bone inwards or outwards, and gently rocking the same towards the acetabulum, while we bring the thigh down parallel with the other. Experience, however, with these dislocations in the living subject, proves this not to be the case, and it seems probable that but few of these cases will be reduced by precisely the same mode of procedure.

In this connection I should like to place upon record an observation I made upon the cadaver while illustrating the several dislocations of the hip, and modes of reduction by manipulation before the medical class of the University last winter. It is well known to surgeons, that in the reduction of dorsal dislocations, either by the pulleys or manual manipulations alone, that the head of the bone, instead of at once passing into the acetabulum, will often fall into the thyroid foramen, and this may occur several times before its reduction is effected. We found that when the obturator internus was intact, this accident did not occur; but upon rupturing or cutting this muscle, without the greatest care on our part this mishap would occur; and, indeed, on two occasions, in spite of all our care, the bone slipped into the thyroid foramen. These experiments were done on a cadaver, where all the soft parts were removed with the exception of the obturator internus muscle and the ilio-femoral and capsular ligament proper.

113 West 44th Street, *March* 21, 1876.

THE TREATMENT OF FRACTURE OF THE NOSE.

By PHILIP A. BISSELL, M.D.,

MAHANOY CITY, PA.

The Medical Record (N. Y.), Vol. 10, No. 17, Nov. 20, 1875, contains an article upon the treatment of fracture of the nose, by means of a cog-wheel apparatus. I will give a history of three (3) cases, which I have treated within the last year, two of which presented the same appearance, the exceptional one which was the second of the three cases which I was called upon to treat, differed from the other two in there being an incised wound through the soft parts at the junction of the vomer with the nasal cartilage. My *modus operandi* is the same as that which is described by Mr. Adams, bringing the parts *in situ* with the aid of the forceps. To hold them in coaptation I simply use sponge tents, withdrawing the old and replacing new ones daily according to the indications of the case. I have not experienced any difficulty from the sensitiveness of its lining membrane or otherwise, in introducing the above-mentioned support into the upper part of the nasal cavity. I select tents which will expand to about the capacity of the nostril. I have not found any need whatever for a steel compressor, or any other instrument with the exception of a strong pair of for-

ceps, to assist me in replacing the fractured portions of bone, etc.

The following is a *resumé* of the cases: Case 1. The fracture was produced by being struck with an iron bar across the upper portion of the nose at the junction of the nasal with the frontal bone, causing a longitudinal fracture of the ossa nasi extending to the inner canthus of the eye upon the right side, breaking the left side into small fragments, and separating the cartilage from the vomer, etc.

Case 2. The patient was struck with the handle of a hoisting machine, causing nearly the same fracture, with the exception of an incised wound at the junction of the vomer with the nasal cartilage, nearly separating that portion of the nose from the face, which had to be held in place by sutures.

Case 3. Patient was struck with a lump of coal which completely flattened the nose upon the face and produced an injury to the supra-orbital arch on the right. All three (3) of these cases were treated with the sponge tents, none of them presenting any deformity excepting from the cicatrices on the soft parts.

I cannot see what advantage the cog-wheel apparatus has over the sponge tents, yet I can see how hollow plugs can and would suggest hard rubber tubes, which could be made compressible by hot water, made conical (if practicable) and introduced into the nasal cavity. They would be better than tents, as they could be left any length of time without removal.

Progress of Medical Science.

Salicylic Acid in the Treatment of Acute Articular Rheumatism.—Salicylic acid, since its introduction into the materia medica, has been very extensively employed as an antiseptic and febrifuge. Its exact value in both of these offices is still apparently *sub judice*. Within a few months, surprising results have been claimed for it in the treatment of acute articular rheumatism, and we give below a summary of the results attained by several recent German observers. Thus Dr. Stricker, from its use in Prof. Traube's wards, declares that it has been found on trial to be a remedy capable of definitely curing recent cases of rheumatic affection of the joints in an exceedingly short time. He does not claim for it the power of absorbing exudations which have already taken place in the joints; in the acute stage he finds improvement is coincident with the fall of the temperature. He considers it harmless, if given in doses of from 7 to 15 grains an hour. While these are safe doses for young and vigorous persons, they may, in those who are advanced or weakly, produce some excitement, with ringing in the ears, deafness and sweating. To prevent relapses, he advises that the acid should be continued in diminishing doses for some days after the chief symptoms are subdued. The acid is of very doubtful utility in chronic rheumatism, and that associated with gonorrhœa and dysentery. Dr. S. uses the pure acid in a pulverized or finely crystallized form.

Dr. Hildebrandt, in the *Deutsche Med. Wochenschr*, No. 7, 1876, gives the details of a case of acute rheumatism, occurring in a girl of eleven, to whom he gave the salicylic acid in doses of 3¾ grains hourly, with the result of complete relief of the symptoms at the end of thirty six hours. It was continued in doses of 1½ grains for some days longer.

At the end of a short article on the various uses of salicylic acid, in which its use in diphtheria occupies most attention, Dr. Robert Buch, from his own experience in a number of cases, confirms the favorable views of Stricker regarding its use in acute rheumatism. With him, too, it has proved unsatisfactory in the chronic form. He prefers to give it, as recommended by Hanow, in solution with phosphate of soda; and not, according to the plan of Schulz, suspended in mucilage.

L. Riess, of Berlin, is inclined to speak more guardedly than Stricker of the action of the acid in rheumatism. Thus he recommends it as a valuable antiseptic in this disease, and says that in many cases, especially when coming early under treatment, a great amelioration of the symptoms is coincident with the defloreseence. From his figures, however, it would appear that the duration of treatment in a majority of cases is not very short. His own plan was to give the remedy in large single doses, combined with soda, as often as the temperature reached 102.2° F., but he afterwards adopted Stricker's so far as to give 15-grain doses hourly; using as before, however, the solution with phosphate of soda, and not the pure crystals. Still his results were much less favorable than Stricker's. He has more recently used the commercial salicylate of soda.

Dr. Julius Steinitz, of Breslau, gives details of three cases, in which he gave to two adults doses of 7½ grains hourly of the pure acid, and to a child of six and a half years 3 grains at the like intervals. The two former were practically free from pain and fever after nineteen and twenty doses respectively, although the second one had been complicated with very violent delirium. The child required but sixteen doses. Dr. Steinitz, too, has found it entirely valueless in chronic rheumatism.—*Berl. Klin. Woch., Feb.* 21, 1876—*Allg. Med. Cent.-Zeit. Feb.* 23, 26, *Mar.* 1 *and* 4, 1876.

The Circulatory Disturbances visible to the Ophthalmoscope in Traumatic Lesions of the Brain.—M. Panas concluded a memoir on this subject, read before the *Academie de Médecin*, with the following resumé of facts, that were established by his observations:

1. Papillary stasis often occurs as a result of the different traumatic lesions of the encephalon (concussion, contusion, wounds, fractures of the cranium, &c.)

2. This stasis in question is not always accompanied by visual disturbances; consequently the ophthalmoscope should be employed in all cases of injury to the head, whether a diminution in the acuity of vision be complained of or not.

3. According to the autopsies made, and according to Schwalbe, this stasis seems to depend on an infiltration of blood or of serum into the sheath of the optic nerve, and is not directly due to the cerebral lesion.

4. The papillary stasis cannot be said to belong to one variety of cerebral lesion rather than to another, nor does it afford us any assistance in judging of the gravity of the lesion.

5. All that can be affirmed in the present state of our knowledge, is that the papillary stasis indicates the presence of an effusion into the meninges.—*La France Médicale*, February 26th, 1876.

Numeration of the Globules in the Newborn.—M. Lépine reported to the *Société de Biologie*, at the meeting of the 12th of February, the results furnished by counting the globules in the new-born. In his experiments, he used the instruments of M.

Hayem, and took the blood from a finger or the great toe. He proved that there is a considerable augmentation of the globules on the day after the birth of the child, but on the second day a progressive diminution in their number begins, and continues for a certain time. In one case M. Lépine found alternating augumentation and diminution, where there was an unhealthy condition of the subject. This diminution of the globules, which begins on the second day and is finished on the eighth day after birth, is in inverse relation to the changes in the weight of the child. On the day after birth there is diminution in weight, due to loss of meconium and increase of the globules. From the second day the weight goes on increasing, while on the other hand the globules diminish. It is important to note that, in pathological conditions, an augmentation of the globules corresponds always with a decrease in weight, while at the same time a diminution in the globules is attended by increase of weight. —*Le Mouvement Médical*, February 19, 1876.

Infantile Paralysis in an Adult.—M. Couty presented to the *Société de Biologie*, on February 26th, a patient aged 28 years, suffering from acute myelitis of the anterior horns (infantile paralysis). The paralysis, a hemiplegia complete in the lower, incomplete in the upper extremity on the left side, appeared suddenly after a fever of four days' duration, without disturbance of sensation or nutrition, or cerebral symptoms. Atrophy of the muscles was appreciable in September, a month after the commencement of the trouble; at present the upper extremity is one to three centimetres, the lower extremities three to eight centimetres, less in circumference on the left than on the right side. The paralysis began to diminish a month and a half after its first appearance, and at the present time all the movements of the limbs can be performed, but their force is diminished, and some of them are very limited. The muscles on the posterior aspect of the leg and thigh contract but very slightly on the application of the faradic current.

There is moreover, a marked hyperæsthesia of the paralyzed muscles, a diminution of one to four degrees in the temperature of the atrophied parts, and finally some very curious disturbances due to vaso-motor paralysis.—*Le Mouvement Médical*, March 4, 1876.

The Ferment of Urea.—M. Museulus has described a new test-paper, by means of which urea in solution can be recognized even when present in very small quantity. He obtained it by filtering ammoniacal urine, washing the filtrate with distilled water, and coloring it with turmeric. This paper contains a small quantity of the ferment in its pores, where it may be preserved for a very long time. When the paper is dipped in a solution of urea, and then exposed to the air, it becomes brown in a few minutes. This change of color is due to the action of the ferment, which metamorphoses the urea, a neutral body, into carbonate of ammonia, without action on the turmeric paper.

Every specimen of urine does not furnish this ferment; some specimens can even be exposed to the air for months in summer without undergoing alkaline fermentation. The thick glutinous ammoniacal urine passed by patients suffering from catarrh of the bladder, is the richest in this ferment. Such urine cannot be filtered, because the mucus in a short time forms an impermeable coating, which stops up all the pores of the paper. If strong alcohol be added to it, however, the mucus coagulates into a mass resembling fibrine, which can be easily isolated from the fluid. This mucus is itself the ferment. In order to preserve it, it must be dried by a gentle heat, pulverised, and placed in a tightly corked bottle. This urea ferment possesses none of the properties that characterise the organised ferments, but has, on the contrary, a great resemblance to the soluble ferments, such as the diastase, the saliva, and the pancreatic juice; in fact, according to M. Bouchardat, acids and alkalies hinder the action of the diastase, while alcohol, ether, and creosote exert no influence over it. The same is true of the urea ferment. Carbolic acid is the only acid that exerts no action on this ferment. —*Bulletin général de Thérapeutique*, February 29.

Acute Glanders.—Dr. John Reddy gives the history of a case of this disease, which came under his observation. The patient, a stout, well-built man, had travelled for three days on a steamer where there were fourteen horses, ten of which were sick, the symptoms being debility and a foul discharge from the nose. He was obliged to take care of them himself. Two of the horses died and were thrown overboard, and on two occasions he was made to vomit by the stench on first going to the horses' quarters in the morning. Four days after leaving the steamer he felt unwell, experiencing peculiar sensations about his limbs and body, not of a painful character, but producing a kind of uneasiness. These continued for four days, when he was seized with a severe rigor, high fever, and profuse sweating. This condition lasted for five days, when a globular swelling, about the size of a goose-egg, was noticed under the right clavicle, extending down to the margin of the third intercostal space. This had arisen the night before, and was exceedingly painful and tender to the touch. Tincture of iodine was painted over it, and warm linseed-meal poultices were applied. The next day the painful swelling of the chest was found to be relieved by the poultices and iodine paint, but there was pain throughout his body and along his arms and legs. Three days after, a new feature presented itself: Along both arms, and from the shoulders to the wrists, and from the hips to the ankles, and in the calves of the legs, about one inch apart, hard, well-defined swellings were felt, projecting somewhat from the skin, and about the size of very small filberts. They were very painful to the touch; and here and there small, dusky, dry, erythematous patches were seen. Along the supra-scapular region there was another globular swelling, a little larger than that which existed on the chest, and equally painful. For this, the same treatment was ordered. The following day the debility was marked, and the perspiration profuse. A tumor, similar to the one mentioned over the scapula, appeared, occupying the crown of the head and a portion of the right parietal bone. Pink streaks along the line of the lymphatics, passing between or along the line of the hard, knotty tumors, were also observed. The patient was languid, and complained of great prostration. On the seventeenth day of the disease, a number of vesicles appeared on the arms and shoulders, which, in the course of a few hours, became pustular. They were not unlike small-pox pustules, and made their appearance in crops. On the 19th day the pulse was 120, and the temperature 103½. There was great prostration, with a short cough and oppressed breathing, and on the twentieth day the patient died. After reading Bollinger's exhaustive article on the subject, in Ziemssen's Cyclopædia, in vol. III., on Chronic Infectious Diseases, and other articles of a similar kind, Dr. Reddy says he could not fail to recognize the great

similarity between them and the case brought under notice.—*Canada Medical and Surgical Journal*, March, 1876.

Morphœa.—At a meeting of the Chemical Society of London, Dr. Dyce Duckworth exhibited an example of this disease, giving the following history of the case: The patient, a male, 26 years of age, had been under observation for four years. The change dated from an attack of headache, when he had observed an alteration in the color and texture of the skin on the left side of the forehead. When first seen, there was a smooth, shiny, slightly depressed patch, which could not be pinched up above the left eyebrow, and it extended upwards over the forehead; the patch also involved the scalp, the hairs of which had fallen out. The surface was dry, no perspiration occurring when other parts of the face perspired, and the sensation was blunted over it, but not lost. The patch slowly grew, a year later was still increasing. About one year after, it was still larger, reaching to the inner edge of the eyebrow, and approaching more nearly the vertex. It was of a dark, raw sienna color, with vascularity here and there, and it was raised above the surrounding surface. Subsequently, the patch became more depressed, especially at the margins, and the color faded, only slight pigmentation remaining here and there, and it became warmer and more vascular than the surrounding skin. It was a curious fact that the disease was confined to the left side in all the six cases that had been recorded in English literature, this being the seventh. Dr. Hilton Fagge agreed with Dr. Duckworth, in the after discussion, that a disease so distinctly localized to the region of one nerve, namely the fifth, should have a distinct name. As to the pathology of the affection, he did not know whether it was due to a definite fibroid growth in the skin, as in the case of ordinary diffused scleroderma; if so, it would be an example of what was at present a doubtful occurrence—namely, the atrophy and absorption in course of time of a true fibroid tissue, as distinguished from a small-celled growth.—*The Lancet*, *March* 4, 1876.

Nervous Aphonia Cured by Inhalation of Chloroform.—Dr. de Ridder, of Liège, reports a case in which these inhalations produced the happiest results. The patient, a woman of twenty-eight years of age, of a good constitution, became aphonic while suffering from an ordinary cold. This aphonia resisted all the remedies employed, after the disappearance of the inflammatory symptoms. As the patient was hysterical, M. de Ridder, thinking that the aphonia was nervous, employed without success, assafœtida pills, and then a narcotico-anti-spasmodic mixture. Finally he made her inhale the vapor of chloroform for one or two minutes every hour, in such a manner as not to produce anæsthesia, but just enough to produce a little giddiness or stupefaction. The aphonia yielded little by little, and at the end of two days had completely disappeared. Five months afterwards, chloroform was again employed with like success for a recurrence of the attack. Finally, a year later, the same aphonia, accompanied by a spasmodic hiccough and incessant vomiting of a glairy matter, showed itself after a violent attack of hysteria. The employment of chloroform, administered in the same way, again succeeded as well as before. The hiccough and the vomiting yielded on the employment of ether.—*Journal de Méd. et de Chir.*, February, 1876.

The Action of Cold on Milk and its Products.—When cow's milk, fresh from the udder, is exposed to different temperatures between 0° and + 63°, and kept at the same temperature for twenty-four or thirty hours, the following results are obtained:

1st. The rising of the cream is more rapid, the nearer the temperature at which the milk has been kept approaches zero.

2d. The amount of cream obtained is greater, when the milk has been exposed to a low temperature.

3d. The yield of butter is also more considerable in this case.

4th. Finally, the skim milk, the butter, and the cheese are of a better quality when the milk has been kept cool.

MM. Tisseraud and Boussingault think that the low temperature arrests the evolution of the living organisms that constitute the ferments, and prevents production of the fermentation due to their action.

In some northern countries the milk is kept at a temperature of 8° to 6°, by means of large basins filled with spring water or even with ice.—*Bulletin général de Thérap.*, February 29, 1876.

Ergot in the Treatment of Galactorrhœa and Mastitis.—Dr. Schtscherbinenkoff observed during an epidemic of raphania that, associated with the symptoms of ergotism, the secretion of milk in nursing women was often diminished or arrested. Recognizing the fact that an accumulation of milk in the ducts is the great cause of parenchymatous mastitis, he prescribed the ergot of rye for two women, who in former confinements had suffered from this trouble, giving it as soon as there was swelling of the glands. The results were most favorable. In so-called milk fever he also gave ergot, combined with quinine, in doses of grs. v.–x. of each three times a day. He also found it useful in arresting the secretion of milk after weaning the child. He gave as much as a drachm daily for a week without unfavorable results. —*Sitzungsberichte d. Ges. russ. Aerzte in Moskau*, 1874. —*Allg. Med. Cent. Zeit.*, May 19, 1875.

Preservation of Meat by the Constant Electrical Current.—Bloch reports that a piece of meat, through which a constant current was allowed to flow, remained unchanged in color and smell after six days' exposure to atmospheric influences; while another piece similarly exposed, but without the electrical current, had become putrid at the end of the six days. He promises to publish further experiments.—*Centralbl. f. d. med. Wissenschaften*, Jan. 22, 1876.

Camphorated Ether in Erysipelas.—According to Cavazzani, a preparation consisting of camphor and tannin, of each one part, and ether eight parts, is an excellent application, even in cases of phlegmonous erysipelas. It is also very efficacious in burns of the first and second degrees; the heat disappears rapidly, and blisters do not form. It should be applied every three hours.

The Dead among the Poor.—The London *Lancet* calls attention to the inconveniences attending post-mortem examinations among the poor. In many instances a whole family occupies but one room. The editor suggests the propriety of establishing mortuary houses in the crowded districts, where not only autopsies can be performed, but where burial can be awaited with decency.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, April 8, 1876.

PRELIMINARY EDUCATION.

If we look over the catalogues of our different medical colleges we shall find that not one-third of the students have received a baccalaureate degree. Judging from the standard of preliminary education adopted in other countries, not one-third of our young men who commence the study of medicine and attend medical lectures are properly qualified to do so. Every one knows that the reason for this is, that the medical schools take any one who may choose to apply, and who is able to pay the fees. It would be so much against their interests to do differently that we can hardly expect them to change their course by insisting upon some method of preliminary examination which would insure a higher grade of intellectual acquirements among the matriculants. Far from doing this, we have seen how much of a disposition there is to trifle with some of the dearer interests of the profession, in crowding upon us graduates who are wholly unfitted for the responsible duty of practitioners, and who have been allowed to evade, not only the letter but the spirit of the law, by being credited with two courses of lectures in one year, and thus actually shortening the term of study. There has been, it is true, a great deal of talk on the part of the medical teachers in regard to the necessities of reform; but, with one or two exceptions in the case of medical colleges, nothing has been done to effect it. Practically speaking, it has amounted to nothing but high-sounding emptiness of promise to drown the clamor against what they know to be their purely selfish interests.

It has long been evident that any change for the better must be made by the profession itself, independent of the colleges. An attempt to effect a very desirable departure from the system of allowing every one to enter a medical college without a sufficient preparation for the study of medicine was made by the American Medical Association in 1871. That body, at the instance of its Committee on Medical Education, passed the following:

"That each State and local Medical Society be requested to provide, as a permanent part of its organization, a Board of Censors, for determining the educational qualifications of such young men as propose to commence the study of medicine, and that no member of such society be permitted to receive such a student into his office until such student presents a certificate of proper preliminary education from the Censors appointed for that purpose, or a degree from some literary college of known good standing."

This resolution was adopted by the Medical Society of this State the subsequent year, and another supplementary one adopted, to the following effect:

"That no member of any medical organization represented in this Society be permitted to receive a student into his office until such student presents a certificate of a Board of Censors, showing his qualifications to enter upon the study of medicine."

Theoretically speaking, these provisions would seem to remedy a very important defect in medical education, but, practically, they became a dead letter. The American Medical Association was seemingly powerless to enforce its regulation, and the State Society, through its county organizations, ignored its self-imposed obligations. There were, however, two exceptions to the rule, in the case of the Medical Societies of Erie, and of Ulster, in this State. Both of these organizations deserve the credit of living up to the principle involved in the resolutions named. The Erie County Medical Society particularly has distinguished itself by a determination to do its duty in this respect, in proof of which we quote the following extract from the Examining Board, made at its last annual meeting:

"Since 1872 a continuous and systematic effort has been made by this Society, to enforce the provisions of its by-laws in relation to preliminary education, as recommended by the State and National Medical Societies. This effort was begun by the Primary Board issuing a circular to all the members this Society, calling attention to the recommendations of the American Medical Association, and our State Medical Society, together with such parts of our own by-laws as relate to preliminary education, and asking for the support and co-operation of all.

"It is not necessary to enter into a detail of all the official acts of this board since 1872; you are fully acquainted with the results of our efforts. These results have been by no means commensurate with the importance of the cause in which we have labored, but have been sufficient to demonstrate to us the entire practicability of this part of reform in medical education, and to afford abundant encouragement to continue our efforts in this direction."

Having done this much, the Society appeals to its sister organizations throughout the State for co-operation, and asks the president of the State Society to bring the matter before that body, and to urge organized efforts in the same work throughout the State. By all means let its example be followed. If such a thing is accomplished, we can at least control to a cre-

tain extent the entrance of unqualified men into the colleges; at least the profession can prove that it is in earnest regarding the work of reform, and can be enabled to hold the medical schools to a stricter responsibility in regard to the qualifications of their matriculants.

INTERNATIONAL CONGRESS OF OTOLOGY.

The American Otological Society has issued a call for an International Congress of Otologists, to be held in New York, on Friday, Sept. 15, at Chickering Hall, the day after the adjournment of the Ophthalmological Congress. Many of the American, and some of the foreign, Ophthalmologists are also Otologists; therefore it is believed that the sessions of this Congress, which are for one day, will be well attended. Delegates from France and Great Britain have already promised their presence.

Reviews and Notices of Books.

Extra-Uterine Pregnancy: Its Causes, Species, Pathological Anatomy, Clinical History, Diagnosis, Prognosis and Treatment. By John S. Parry, M.D., Obstetrician to the Philadelphia Hospital; Physician to the Department for the Diseases of Women in the Presbyterian Hospital; Vice-President of the Obstetrical Society of Philadelphia, etc., etc. 8vo, pp., 272. Philadelphia: Henry C. Lea. 1876.

This obscure branch of midwifery has recently attracted unusual attention in various medical journals, and has been brought prominently before many of the Obstetrical Societies for discussion; but the profession has long felt the need of some special treatise, presenting a full historical record of cases, describing their pathological anatomy, and discussing the various and most approved methods of treatment.

Dr. Parry has fully satisfied this want in the book before us. The work is based upon the analysis of 500 cases of extra-uterine gestation, collected and arranged so that the views of various observers may be readily compared.

Of these cases Dr. Parry has made a most critical and searching examination, closely discriminating between statements based upon conjecture and speculation merely, and facts deduced from large clinical experience.

While the various parts of the treatise contain many original and valuable suggestions, the sections on pathology and treatment are especially excellent, and show an extraordinary amount of research and care. The tabular presentation of the subject of gastrotomy leads to important practical conclusions.

The book will doubtless have an extensive circulation, and will greatly aid the student of this recondite department of medical science.

Dr. H. Lenox Hodge's Note Book for Cases of Ovarian Tumors, and other Abdominal Enlargements. Philadelphia, Lindsay & Blakiston: 1875. Pamphlet, p. 35.

In the preparation of this little book, modelled as it is in the main upon that first suggested by Spencer Wells, nothing appears to have been omitted which could contribute to thoroughness and accuracy of diagnosis, or to a systematic record of the history and progress of a case. No one could devise anything better for the record of his first cases; but as they accumulate, everyone, probably, would introduce changes in the plan to suit his own ideas of classification. A page on which post-mortem appearances may be noted appears to be a desideratum, unless, indeed, one can be so sanguine or so charitable as to believe that the skill of ovariotomists has now become so great that an autopsy never enters into their calculations.

The Physician's Visiting List for 1876. Thirty-fifth year of its publication. Philadelphia: Lindsay & Blakiston.

It still continues to be an agreeable and valuable pocket companion for the medical practitioner.

Reports of Societies.

OBSTETRIC SECTION.

NEW YORK ACADEMY OF MEDICINE.

Prof. Isaac E. Taylor, Chairman.

A stated meeting was held at the residence of the Chairman, March 20th, 1876.

Prof. Taylor with brief and appropriate remarks welcomed his guests, thanked the members for their suffrages in making him their presiding officer, and pointed out what should be accomplished by the section. The regular order for the evening being

PHANTOM TUMORS.

Dr. Chadsey referred to a condition which he had met in a woman, 40 years of age, who had never borne children. The lower part of the abdomen was distended by a hard tumor that pressed upon the bladder to such an extent as to render catheterization necessary. The bladder being emptied, an active cathartic and emetic were administered, the catamenia appeared, not very profusely, and the uterine tumor was reduced to its natural size. The enlargement had been felt by the woman for some time, but with the return of the menstrual flow had entirely disappeared. Inquiry: Was it congestion of the uterus, or something else?

Dr. Worster remarked that he had seen cases in which venous congestion depending upon flexions had been developed to such an extent as to give rise to a condition closely resembling what is commonly understood by the word tumor; but which had entirely disappeared when the neck of the uterus had been straightened and a certain amount of local dissection made. He referred to one case in which the pelvis was filled with a uterus that was enlarged in consequence of arrested return circulation dependent upon flexion. The flexion removed, the parts were restored to their normal size.

Dr. Downs referred to a case which he thought might be classed under the head of

UNUSUAL UTERINE HEMORRHAGE.

He was called to visit an unmarried German girl, æt 28 years, and found her pale and almost pulseless, on account of loss of blood from the uterus. A piece of ice, as large as could be used, was at once introduced

into the vagina and carried up to the cervix. The os was open to about half the size of the index finger, a trifle soft about the edges, and situated to the left side of the pelvis. The body of the uterus could be easily recognized lying to the right side of the pelvis, and when pressed upon gave a sensation to the finger as though it contained fluid. A bandage was adjusted to retain the ice in position, and drachm doses of equal parts of fluid extract of ergot and paregoric were administered every half hour until the flow ceased.

The blood which was lost clotted quickly, was of a bright red color, and was something more than three quarts by measure. It was closely examined, but no evidences were found which led the doctor to believe that the flow depended upon a miscarriage.

The woman had not had her courses as freely for three or four months as usual, otherwise they had been regular.

At the end of two weeks, the doctor was not able to make anything more of the case, and came to regard it as one of uterine congestion, which relieved itself suddenly in the way of this profuse flow.

ANTISEPTIC TREATMENT OF DIPHTHERIA.

Dr. Post referred to a patient whom he was called to visit in the morning, a boy 3 years of age, who had very considerably swollen tonsils, with diphtheritic patches upon them; considerable mucous discharge from the nasal cavities; and glandular enlargement with tenderness at the angle of the jaw. The doctor at once prescribed bromine with bromide of potassium, after the following formula:

℞ Potass. Bromid. ʒ i.
Aquæ ʒ i. M.

Dissolve in the solution of bromide of potassium, twenty minims of bromine.

Of this mixture administer gtts. x in a teaspoonful of water every hour.

The nasal cavities were hourly washed with a solution of common salt in water, a teaspoonful of salt to the pint of water; and one grain of sulphate of quinine given in solution every two hours. To these were added a tablespoonful of milk-punch every hour.

In the evening the patient was found breathing with much greater ease than in the morning, and was sitting up in bed.

This single case simply showed something for the disinfectant plan of treatment.

Dr. Post also referred to another boy, æt. 9 years, who had the disease much worse than the boy just alluded to, and the solution of bromine with bromide of potash was applied by means of a swab, because the patient made no resistance, as was the case in the other patient. In other respects, the treatment was the same. In the latter case also there was marked improvement at the second visit; and at the end of four or five days the patches of diphtheritic exudation had all disappeared and the patient was fairly convalescent.

Three weeks subsequently, the boy had double vision, which was treated by the use of strychnine in 1-60 gr. doses thrice daily, and complete recovery followed.

There was another child of the family at that time, and he was removed from the house. He, however, was attacked with diphtheria a few days afterwards; and, apparently, was no worse than the boy who was, under Dr. Post's care, but the case proved fatal.

Dr. Downs inquired whether the dose of milk-punch given to a boy three years of age was not rather large?

Dr. Worster remarked, that he regarded stimulants as the sheet-anchor in the treatment of diphtheria.

Dr. Post further remarked, that he believed it a fair inference, that whatever benefit was derived from disinfectant remedies, came rather by using them at short intervals and in doses of corresponding size than in larger doses given at longer intervals.

The Chairman referred to the susceptibility manifested by certain patients relative to the action of strychnine, and mentioned one case where marked rigidity of muscles was developed soon after the administration of the second dose of $\frac{1}{60}$th of a grain; and another case where $\frac{1}{120}$th grain doses produced the physiological effect very rapidly.

Dr. Caro remarked, regarding the use of bromide of potassium in the treatment of diphtheria, that it was his main reliance, and had been for the last fifteen years. The doctor maintained that there was nothing which dissolved the membrane with greater certainity than this drug. He employed it in solution of the strength of one drachm to the ounce of water, and commonly applied it in the form of spray. Whenever the breathing became dry, he at once resorted to the spray for a few moments, when the child usually commenced to breathe more freely, and, in many cases, coughed and threw out patches of membrane. He recommended its early use, as there was no more efficient method of relieving capillary congestion.

Dr. Finnell remarked, that it was difficult to know what was meant by the term early. When the membrane was formed, the disease was developed; and, prior to that time, how were we to tell whether it was a case of diphtheria or not?

Dr. Caro replied, that when he noticed an increased redness in the throat in a patient who complained of the chilly sensations, general malaise, aching limbs, headache, etc., symptoms commonly attending diphtheria, and the patient had been within the influence of the disease, he did not wait for the formation of the membrane, but at once resorted to measures to reduce the capillary congestion; and for that purpose there was nothing better than the bromide of potassium. Whether such a case was to develop into one of true diphtheria, he was not able to say; but if it did prove to be a case of diphtheria, the remedy which he wished to use had been commenced early; and if it did not prove to be one of diphtheria, certainly no harm was done.

Dr. Finnell continued, that he had not saved a single case in which the membrane had become formed, and inquired of Dr. Caro if he could point to any cases of diphtheria which had got well under his plan of treatment?

Dr. Caro in reply, cited six cases in one family with recovery in every case.

Dr. Finnell said, he believed the best thing for himself to do, then, was to change his location.

Dr. Purple mentioned the fact that the first written description of the disease known as diphtheria, was by Dr. Cadwallader Colden, a New York physician, in the year 1753. Dr. Bard wrote his celebrated paper on Angina in the year 1771, and from this, Bretonneau, in his writings upon this affection, had taken almost the exact language.

Dr. Castle remarked, that in Ziemssen's Cyclopædia there was evidence that the disease was known far back among the Arabians.

SUDDEN BLINDNESS ASSOCIATED WITH PREGNANCY.

The Chairman stated, that he had under observation two cases of utero-gestation, in both of which

loss of vision was suddenly developed, without œdema or premonitory symptoms of any kind. Without theorizing at all, the question arose what should the treatment be for that class of cases? One of them was in the sixth, and the other in the seventh month of pregnancy. The urine had a specific gravity of 1015 to 1020, and contained considerable albumen and some epithelial casts.

One patient was totally blind in one eye, and could see only slightly with the other. From the experience which Dr. Taylor had had in such cases, he recommended the induction of premature labor; for, the great danger was the development of convulsions.

Premature labor could be completed in from thirty-five to forty-five minutes, and delays were dangerous. He was of the opinion that in nine out of twelve cases of this character, the measure would prove a success, and save the life of the woman. So far as the child was concerned there were grave doubts with regard to its viability in any event, as it doubtless felt the powerful impression produced by the circulating poisonous element.

Dr. Hubbard inquired concerning the quantity of water being passed by the patient to which particular reference was made?

Dr. Taylor replied that she was passing about one quart in twenty-four hours, but that he had had just such cases where one gallon was passed within the same length of time.

Dr. Hubbard believed that if the kidneys could be made to act so that the proper quantity of urine would be discharged, such patients can be carried through without resorting to premature labor. He further remarked that he had had three such cases, at fifth, seventh, and eighth months respectively, and all went through safely.

Dr. Taylor inquired whether the eyesight was affected in those cases?

Dr. Hubbard replied that it was not, to any great extent.

Dr. Taylor remarked that, he regarded that symptom, its sudden development without œdema, as the particular feature of his cases; and that, in that particular class of cases, premature labor offered the best results.

Dr. Hubbard believed that, if the woman should receive tablespoonful doses of infusion of digitalis, she would go safely through the night; and from that she could be safely carried through to term.

Dr. Taylor said that the woman had already been carried along for ten days, was perspiring freely, and seemed quite comfortable; but at his evening visit there were some twitchings, and he would not be surprised at any moment to receive a call with the announcement that the woman was in convulsions. The point in the cases was the suddenness with which the symptoms were developed. The albumen in the urine had no special significance except as it pointed in the direction of danger.

Dr. Finnell inquired of Dr. Taylor whether he would perform premature labor before convulsions were developed?

Dr. Taylor replied no; unless there were prominent symptoms indicating their approach.

Dr. Post inquired of Dr. Taylor if he had bled any of this class of patients, before convulsions had taken place?

Dr. Taylor replied that he had not.

Dr. Post then referred to cases in which he had given relief from the threatenings of convulsions by blood-letting; but he had never had occasion to employ it in cases where sudden blindness was present. In the light of his experience, however, he should regard such cases as proper ones in which to resort to this measure, and preferred to first determine what blood-letting would do, in cases which would admit of it, before resorting to premature labor.

Dr. Finnell inquired of Dr. Taylor, how he performed the operation?

Dr. Taylor replied that he ordinarily used Barnes' dilators, until the os internum was dilated to the size of a silver quarter; and then, introducing one or two fingers, performed external version, bringing the breach down, when one or both knees or feet will drop into the hand, when they can be seized, brought down, and the labor very soon completed.

Dr. Finnell inquired what objection there could be to the introduction of first one finger, then a second, and then a third, for the purpose of dilating the os?

Dr. Taylor replied that the dilatation could not be properly done in that manner, for it is the os internum that must be dilated, and the dilator must be carried above that point.

The hour of ten having arrived, the section adjourned to an adjoining room, where difficult cases and local applications for throat diseases gave place to a delicious prescription for gastric disquietude.

NEW YORK MEDICAL JOURNAL ASSOCIATION.

Stated Meeting, March 24th, 1876.

Dr. E. G. Loring, President, in the Chair.

Prof. M. A. Pallen read a brief but interesting paper upon the mechanism, prevention, and treatment of

PERINEAL LACERATION.

The anatomy of the perineal body was first studied; and it was noticed, as the reader passed to the question of mechanism, that he used the term "procession of the vulva," instead of "retrocession of the sacrum." Under the head of Prevention, Dr. Pallen recommended that, in certain cases, liberal incisions should be made upon both sides, but always above the ducts of Bartholini, and in the interval between labor-pains.

Among the accidental causes of this lesion were mentioned laceration of the cervix, which might permit the head to be driven upon the perineum before it became sufficiently distended to safely resist the pressure; unskilful instrumentation—not that it necessarily attended the use of instruments, for the forceps might save a perineum—but when predisposing causes were present, they might give rise to rupture; unusual size of the fœtal head, perhaps complicated with small vagina and vulva; undue amount of adipose tissue; ulcerations of the fourchette, etc. The predisposing causes were divided into vulvar, vaginal, and pelvic. If the head were suddenly protruded from the vulva with a sharp pain, it was maintained that the attendant might suspect a perineal rupture. For, when the uterine forces were active, and the head was driven through the cervix before proper dilatation could take place, and thus made to descend upon the perineal structures, or when certain other accidental and predisposing causes were present, it was maintained that no skill could prevent laceration. It was believed that many ruptures occurred which passed unnoticed. The doctor, in general terms, dissented from the opinion that perineal lacerations heal spontaneously. Under the head of treatment, Dr. Pallen

advised the immediate application of silver-wire sutures, unless the exhaustion of the patient precluded the operation. He urged immediate operative interference, if possible; on the ground that in no single instance had he seen a perfect restoration of the parts in the cases where spontaneous union had been said to have taken place. In all the cases he had seen, the fourchette had been found destroyed, and the muscles had always been found separated. It was maintained that sutures were the only sustentative measures which should be employed, that they should be deep, and not more than a line apart, and should be supplemented by superficial sutures in each inter-space; that the bowels should be kept soluble by warm enemata, and not constipated by opium, after the common rule; that the vagina should be kept well cleansed; the bladder well emptied; and that advantage might be derived if the nates of the patient were placed in an India rubber ring cushion filled with air. The doctor claimed that no operation for the restoration of the perineal body should be undertaken before determining the position of the uterus, and the condition of the cervix. Retroversion always attended a perineal laceration. The conditions demanding an operation were considered under four heads: Perineal Sundering, Vaginal Sundering, Perineo-rectal Sundering, and Recto-coccygeal Sundering. Dr. Pallen has been successful in nearly all his operations.

Dr. Munde believed that he had prevented laceration of the perineum by resorting to the lateral incisions of the vulvar orifice to which reference has been made by Dr. Pallen. He should hesitate, however, before resorting to the operation in private practice. The plan for prevention which he recommended was that of introducing two fingers into the rectum, and, catching on the malar surfaces, rolling the head from the perineum, at the same time pushing the fourchette backward. Mere support from the outside he regarded as being of no use whatever. Success had attended only about 55 or 60 per cent. of his operations in this class of cases. With regard to the sundering of the muscular structure of the perineum, Dr. Mundé supported the view taken upon that point by Dr. Pallen.

Dr. Darby remarked that there were many operators who performed this operation after a particular method; but that, after all, they were only modifications of the principle first elaborated by Baker Brown. The doctor also maintained that, in fact, all that was really practical had reference to complete and incomplete ruptures; that is, whether or not the sphincter ani muscle was involved. He also spoke in favor of deep sutures, and that some non-absorbing material was always preferable where it is desired to have union take place without being attended by ulcerative action. In that respect there had, perhaps, been some advance made upon the method given by Baker Brown. Cutting the sphincter might be necessary, in order to keep everything at rest, but it should be done subcutaneously, and cut from without in, which would be sufficient to give rest to the deeper parts. Dr. Darby argued in favor of quill sutures, and believed that wire sutures twisted over the edges of the wound in the ordinary manner should never be trusted to close the deeper portions. He also believed that, in many cases, the rupture healed entirely where the woman had been kept in the proper position.

Dr. Gillette thought that he had been unsuccessful in about 60 per cent. of his operations for the cure of rupture of the perineum. He also believed that much could be done in way of prevention, by introducing the fingers into the rectum, and proceeding in the manner already mentioned.

Dr. Messinger had seen some ten or twelve hundred cases of labor, with only one rupture of the perineum of sufficient importance to demand subsequent attention. He argued in favor of manipulation for prevention, and chiefly in the way of controlling the too rapid descent of the head.

New Instruments.

A NEW ETHER APPARATUS.

By OSCAR H. ALLIS, M.D.,

SURGEON PRESBYTERIAN HOSPITAL (PHILADELPHIA).

The apparatus consists of a wire frame-work, sufficiently large to cover the lower part of the face. The wires are parallel, and about an eighth of an inch apart. Between the wires, from side to side, a strip of bandage two and one-half inches wide is passed. The instrument is only about four inches long and three inches at its greatest width, and yet it consumes more than three yards of bandage when passed between all the wires. By further reference to the figure it will be seen that each section of the bandage is separate from the adjoining one, thus permitting the air to pass freely to both sides of it. I usually supply the ether from a graduated bottle furnished with a dropper-cork, as by such a convenience I can add

the ether as gradually or as rapidly as the case may demand.*

My mode of using it is as follows:—Placing it over the face, I sprinkle on *a few drops* of ether,—I mean literally but a few drops. In a few seconds I add a few more drops; and usually in from half a minute to a minute I find that I can drop it more constantly. As soon as I notice *the deep inspirations*, I pour on a small stream, watching carefully least I irritate the larynx, and as soon as I find the patient tolerant of its vapor, I add it in larger quantities, and as rapidly as can be evaporated, and am usually gratified by seeing my patient pass *quietly* under its influence in from three to ten minutes.

Now it may be asked, *What advantages* does this possess over the towel and sponge?

1. It possesses a much larger evaporating surface than either. The whole amount of bandage consumed is eleven feet and two inches, and the entire evaporating surface is over seven hundred square inches. No two of its folds touch, and hence the ether cannot remain in a fluid, but must rapidly assume the ethereal

* Such a cork can be had at any drug store, and will be found of great convenience.

state. The instrument is just sufficient to cover nicely the nose and mouth—does not interfere with vision, and yet in so compact a form furnishes the vapor in a more concentrated form, for the amount of ether expended, than any instrument with which I am acquainted.

2. With so large an evaporating *surface*, there must be *rapid evaporation of ether*, *rapid anæsthetic effect*, and *economy of ether*. The amount of ether consumed is always in direct ratio with the time required to effect anæsthesia. When I use but *two ounces*, the patient is usually ready in six minutes.

3. The instrument is designed to cover accurately the nose and mouth, so that there is no escape of ether at the end applied to the face. In this, it presents a marked contrast with the usual mode of administration. The tendency of the vapor of ether is to escape, not at the top of an instrument, but, owing to its great specific gravity at its most dependent portion. This instrument is open at the top, first, because there is a minimum waste of ether by such an arrangement; secondly, because it permits the ether to be dropped on constantly and in small quantities; and thirdly, because such an arrangement permits the operator to impregnate the respired air to any desired degree through a *constant* supply.

4. There is no exclusion of air, and if properly used, there is not the slightest laryngeal irritation.

To avoid this, one must bear in mind that a few drops at a time are all that are required for the first one or two minutes, when *gradually* it can be increased to any desired degree. By this means we may avoid also the resistance that is often shown when ether is given rapidly at first. In my entire use with the instrument, I have rarely required any assistance in governing the patient, and in a large per centage of cases they pass under its influence without a struggle. I have given it frequently for Dr. Washington L. Atlee during the past year, and in not a single case was there voluntary resistance or a perceptible stage of excitement.

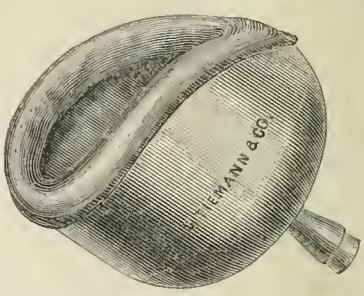
5. The instrument is especially serviceable when a prolonged use of ether is required. A slight *dripping* will suffice to prolong the effect, and economy of ether, though not a great desideratum, is still worthy of consideration.

A MODIFICATION OF LENTE'S ETHER INHALER.

By F. D. LENTE, M.D.

It is probable that the profession begin to think that they are going to be overwhelmed with as many varieties of inhalers as of vaginal specula; but, as the writer was a pioneer, so to speak, in the defence of ether as against chloroform, and the contriver of the first ether inhaler in this country, he may be pardoned for calling attention, after the lapse of so many years, to a modification of his apparatus, especially as it secures a marked simplification and a great reduction in the prices, its former complexity and consequent high price being apparently the only obstacles to its general introduction.

A person thoroughly conversant with the use of ether can succeed quite well, though with a waste of the drug, and greater annoyance to the operator and assistants, with an extemporized apparatus, a towel and stiff paper formed into a cone, or a cup sponge enveloped in some impervious material. The great objection, however, to a soft apparatus is that its air space is liable to be, and almost invariably is, much contracted during the struggles of the patient by the pressure exerted upon it either by the administrator or the patient, who frequently clutches it and gets it



out of shape, and by losing its stiffness from other causes, so that, as the writer has not unfrequently seen, the patient's struggles are mainly caused by having but little chance to breathe either air or ether. The writer formerly contended that, in using the inhaler, the admixture of air should be prevented *as far as possible*. This was owing to the imperfect fitting of the different parts of the instrument, and of the cushion to the face, more air than necessary being thus admitted. With the present apparatus, however, its improved shape, and better fitting cushion, all entrance of air may be prevented, which was never considered desirable. An arrangement is, therefore, made for the admission of more or less air at the apex of the cone. But, at the same time, the writer adheres to his original idea that *but little air* should be admitted after the patient *is able to breathe with tolerable facility* —that is, if we desire *rapid* etherization, which is *not* desirable if the *operation* is to be a protracted one. He is, therefore, of the opinion that the recently contrived *open* inhalers will eventually be superseded in the hands of those who have the opportunity to become thoroughly acquainted with the operation of both, by the conical forms, with a more restricted admission of air. Lately, when called upon to give ether repeatedly to a brother surgeon for operative procedures, he used Allis' open inhaler, and the extemporized cone (towel and napkins) successively, and both the patient and the assistant physicians noticed a marked difference in favor of the latter.

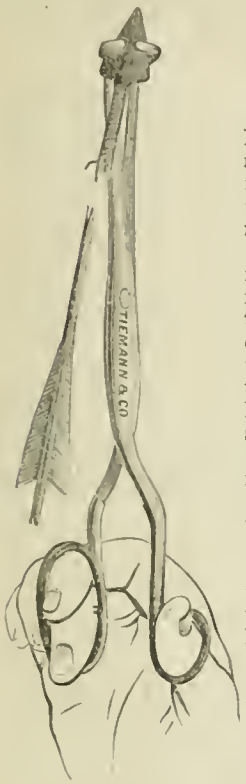
The present instrument resembles very much the face-piece of Waldenburg's apparatus for condensing and rarefying air; and the idea of using sheet brass and the india rubber *air*-cushion was indeed taken from it. But the air-cushion is a failure, as almost all *inflated* things are, without an improvement suggested by the writer, the stuffing of the tube first with hair, so that, when the air leaks out, the cushion will still retain sufficient of its rotundity to fit the face air-tight. When it is to be used, a handkerchief, or piece of sheet lint, etc., is stuffed into the cone, a wire or whalebone arrangement slipped in to keep it off the face, and it is ready. There is a *hole* in the stopper to admit air, and if more air is needed the stopper can be removed. The ether can be poured in the opening at the apex, in case it is undesirable to remove the cone from the face, or throw it on the cloth. Its cleanliness is perfect, as a different piece of cloth may be used each time.

It will have been noticed by some that Golding Bird has a description of an inhaler in the August number of the London *Lancet* which resembles this very closely. But he has two *valves*, one at the top to

admit air, and one near the base to carry off the expired air and ether. Mr. Pfarre, of 67 Chatham Street, informs the writer that Luer, many years ago, had a contrivance very similar to this, but it has been laid aside and apparently forgotten. It is very likely, however, that an arrangement similar to this for getting rid of the effete air may render etherization less unpleasant, during its early steps at least. We must not forget, however, that while so little oxygen is admitted to the lungs, much less carbonic acid requires to be exhaled.

PALATKA, FLA.,

FORCEPS FOR THE EXTRACTION OF ARROW-HEADS.



BY J. H. BILL, M.D.,

SURGEON U. S. ARMY.

I HAVE devised the forceps represented in the wood-cut for the extraction of arrows, which have been made for me by Tiemann & Co.

The cut describes itself sufficiently, but I will add that for arrows not lodged in bone they should be introduced closed, and used as a snare by which the iron or flint point of the arrow may be entangled. For an arrow lodged, they are to be introduced closed, carried down alongside the flat surface of the arrow-head, opened, and then closed on the foreign body.

In length they are nine inches. From the points to the joint—which must be very strong—is two and a half inches. The handles are crossed, and provided with a ring large enough to admit three fingers. The points are one-half inch or a little less across.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department United States Army, from March 26th to April 1st, 1876.

BENTLEY, E., Assistant Surgeon—Assigned to duty at Camp Independence, Calif. S. O. 25, Department of California, March 18, 1876.

CARVALLO, C., Assistant Surgeon—Ordered to Fort Union, N. M., for medical treatment. S. O. 32, District of New Mexico, March 24, 1876.

FINLEY, J. A., Assistant Surgeon—Granted leave of absence for one month, to date from June 1, 1876, with permission to apply for an extension of one month. S. O. 54, Department of the Missouri, March 23, 1876.

BEDAL, S. S., Assistant Surgeon—To report to Lieut.-Col. G. P. Buell, 11th Infantry, for duty as Senior Medical Officer with the "Scouting Camp" to be established on Devil's River, Texas. S. O. 50, Department of Texas, March 22, 1876.

Medical Items and News.

CONTAGIOUS DISEASES.—Comparative statement of cases of Contagious Disease reported to the Sanitary Bureau, Health Department, for the two weeks ending April 1st, 1876. WALTER DE F. DAY,
Sanitary Superintendent.

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro Spinal Meningitis.	Measles.	Diphtheria.	Small-pox.
March 25th.....	0	7	70	3	62	71	28
April 1st.....	0	4	76	5	65	71	26

THE ACTIVE ELEMENTS IN VIRULENT FLUIDS.—At a recent meeting of the French Academy, a lively discussion took place between Chauveau and Colin, the former maintaining his well-known views that in infectious fluids, the agents are minute solid particles, the latter insisting that fluids may still be poisonous when they have been deprived of every particle.

ANDRAL.—Andral, whose death was noted in the last issue of THE RECORD, became a Doctor of Medicine in 1821; after the death of Bertin in 1828, he became Professor of Hygeine; in 1830, he assumed the chair of Internal Pathology—in 1839 was the successor of Broussais in the chair of pathology and general therapeutics. As an instructor, he soon obtained a remarkable reputation. In 1829, he published his *Traité d'Anatomie Pathologique*. In 1834, a third edition of his *Clinique Médicale* had appeared. Andral also published an edition of Laennec's Works in 1837. Between 1840 and 1842, he prepared his *Hemalologie*, in conjunction with Gavarret and La Fond. In 1843, he published his *Traité d'Hemalologie Pathologique*.

PRELIMINARY EDUCATION.—At the close of the medical department of Michigan University, the faculty said that although the requirements for graduation had been increased, the number of failures had been less than at any examination in many years. They report, further, that the movement for preliminary examinations which was begun at this institution has been attended with many good results. It is the design of the faculty to increase the requirements for admission and graduation as rapidly as is consistent with the interests of all concerned.

THE BROMIDE OF ETHYL.—In a communication to the *Société de Biologie*, M. Rabuteau states that the physiological effects of this substance are precisely the same as those of ether. It is, however, less disagreeable to the taste.

GERMAN STUDENTS AT GERMAN UNIVERSITIES.—In the *Gazette d'Augsbourg*, the number of native German students matriculated at Berlin, is given as 1,884; at Leipsic, 2,575; at Munich, 1,087. The theological students number respectively 162, 327 and 84; the law students 807, 1,130 and 257; the medical students 263, 869, and 307; the students of philosophy 911, 1087, and 555. In point of numbers, Munich excels in its instructors, so far as regular professors are concerned, for they have 69 to 61 of either Berlin or Leipsic. Munich has 20 extraordinary professors and honorary professors; Berlin 33; Leipsic 55. The number of private instructors is, 20 in Munich, 73 in Berlin, and 47 in

Leipsic. In Munich there are 9 regular professors in theology; in Berlin, 6; in Leipsic, 7. In the law faculty of Munich there are three regular professors more than in Berlin, and the same number as in Leipsic. The medical faculty of Munich comprises 15 regular professors; Berlin 13, Leipsic 10. The philosophical faculty at Munich includes 31 regular professors, Berlin 33, Leipsic 32.

Parisian Medical Students.—The number of students of medicine registered this year by the Faculty of Medicine, is six thousand five hundred. Six millions of francs have been voted to the city of Paris for the erection and perpetual endowment of additional buildings for this renowned medical school.

Graduates in Dentistry.—Only one hundred and forty six gentlemen graduated from the different Dental Colleges during the recent commencement season.

An Ancient Æsculapian Temple.—A Monolith has been recently discovered in the rear of the Cathedral Nôtre Dame, which is said to prove the existence of an ancient temple, dedicated to Æsculapius. According to a writer on antiquities it is supposed that this temple existed on the present site of the Hôtel Dieu.

Death of Dr. Parkes, F.R.S.—Dr. Parkes, the well-known author of the work on Hygiene, died at his residence in Netley, March 15.

Johns Hopkins' Hospital.—It is proposed to make the medical department of this institution independent of students' fees.

Typhoid Fever from Infected Water.—An epidemic of the above has recently appeared in Breslau. Over six hundred persons have been attacked.

Harlem Flats Nuisance.—Considerable anxiety being manifested in regard to the sanitary condition of Harlem Flats, Profs. Chandler and Day, of the Health Board, accompanied by Sanitary Inspector Viele, recently made a sanitary inspection, in order to recommend some measures for improvement. Three years ago the locality east of Third avenue, between Ninety-third and One Hundred and Second streets, was completely submerged by tide-water, which, in conjunction with the sewerage from the west side of the avenue, produced unhealthful odors. The ground at this low point was filled in during 1874 and 1875, so as to bring it above tide-water, in many cases the filling being to a depth of fifteen feet. In the area between Second and Fifth avenues, and One Hundred and Sixth and One Hundred and Ninth streets, similar difficulties were encountered, and the same policy was adopted. The streets were built up above tide-water, with the exception of One Hundred and Seventh street. At present it is two feet below the highest tide-water, and the land between One Hundred and Sixth and One Hundred and Eighth streets is completely under water at certain seasons. The Commissioners think that by raising One Hundred and Seventh street to the level of the surrounding streets, they will compel the owners of lots on both sides of it to fill in their property. It is thought that the cost of this improvement will not be over $15,000.

Prof. Joseph Fayrer, of India, of cobra poison fame, has been made Knight Commander of the Order of the Star of India.

The Plague has reached Bagdad, where there are ten cases daily. An Egyptian quarantine of fifteen days is established for all arrivals from the Persian Gulf.

The Instruction of Idiots.—In order to make a proper classification of the inmates of the Idiot Asylum on Randall's Island, the Superintendent has been directed to prepare for occupancy the building formerly known as the "Baby Nursery," and the Resident Physician will so select its occupants that the teachable inmates shall be completely separated from the others who are more seriously affected.

The Surgical Congress of Europe is to meet in Berlin, April 19th.

Bellevue Medical College.—Dr. Wm. M. Polk has been appointed lecturer on Materia Medica at Bellevue Hospital Medical College.

John Morgan, F.R.C.S.I., Professor of Anatomy in the Royal College of Surgeons, in Ireland, died in Dublin, Saturday, March 4, of enteric fever, aged 47 years. His skill as a teacher, and his success as a surgeon secured for him an enviable reputation. His studies in anæsthesia, which commanded so much attention at the time, resulted in the re-introduction of ether in Irish surgical practice.

Opium Trade.—The Anglo-Oriental Society has urged upon the British Government the desirability of restricting the opium traffic in China and the Indian Archipelago.

Molecules in the Germinal Matter of Eggs.—Mr. Sorby, in a paper recently read before the Royal Microscopical Society, London, in speaking of Darwin's Pangenesis theory with reference to the number of molecules in the germinal matter of eggs, and the spermatic matter supplied by the male, says that in $\frac{1}{10000}$th of an inch cube he reckons:

Albumen.....	18,000,000,000,000 molecules.
Water	992,000,000,000,000 "
	1,010,000,000,000,000

or in a sphere of the same diameter, 530,000,000,000,000 of the two components.

According to Pangenesis theory, the remarkable facts of inheritance, extending even to the reproduction of unimportant peculiarities of parts or organs, and the occasional outbreak of ancestral characters that have been dormant through several generations, are accounted for by the supposition that each part of an organism contributes its constituent and effective molecules to the germ and sperm particles. These dormant germules must be extremely minute, as well as extremely numerous. Mr. Sorby assumes that they may be spheres, each containing a million molecules, and that one thousand of them would make a mass just within the reach of microscopic vision—all of which we recommend to the diligent student of microscopy.

Original Communications.

MATERIA MEDICA, THERAPEUTICS, AND PHARMACY OF THE ANCIENT EGYPTIANS.

By CHARLES RICE,

NEW YORK.

The progress of the exact sciences has in modern times so much absorbed the attention and study of all interested, that only a comparatively small number have been willing or able to devote some of their leisure to the history of the various branches of natural science in the past. The importance of these historical investigations is often overlooked or underrated, and we should welcome any positive additions made to our knowledge of the state of the arts and sciences in ancient times.

Medical science, and in its wake pharmacy, although now standing on a sounder basis than of old, owing to the strictly scientific experimental and inductive methods pursued in its various fundamental departments, may still derive much indirect advantage from a study of their own past. In the writings of the great ancient physicians, as a rule, calm judgment, sound common sense, and a multiplicity of resources under the most trying and difficult circumstances, stand out broadly from among the mass of antiquated and worthless material, and many a hint may even yet be gathered therefrom and used with advantage by the modern followers of Æsculapius.

During the month of September of last year I received, for inspection, the first copy of the Papyrus Ebers which reached this country. I made extensive extracts at that time, intending to publish whatever might be of interest, and contribute to the history of medicine and pharmacy, but I could not find time to work up my materials into a connected shape. Since then, the late librarian of the Astor Library in New York, which possesses a copy of the work, has published a brief but excellent account of the work in the *N. Y. Tribune* of Nov. 9, 1875, which has found its way into various journals (as, for instance, the *Chicago Pharmacist* of November; see also Dr. H. C. Bolton's paper in the *American Chemist*, Vol. 6, No. 5); and some of our readers probably possess already a general knowledge of the character of the work. The account given in those papers, however, is not nearly as full as the antiquity and importance of the work deserve; and I determined therefore to give such additional information of its contents as seem to be of interest. In doing so, I shall leave out all philological material not necessary to the subject, giving only that, which may throw some new light upon the derivation of technical names, or in some way may aid us to understand the facts stated. But in order to put those, who have not as yet seen the previous accounts of the work, in possession of the necessary facts, I will briefly repeat them here.

During the winter of 1872–73, Dr. George M. Ebers, Professor of Egyptology at the University of Leipzig, and Mr. Ludwig Stern, of Berlin, purchased in Egypt a papyrus-roll of a size and beauty exceeding any previously known. It was found to be a complete work, measuring 30.23 metres in length, by 30 centimetres in width. The writing is one side only, excepting near the end, where it runs over on the back; the letters are hieratic, beautifully clear and black, with frequent interspersions of headings and marks of weights and measures in red. Its age was determined by Prof. Ebers by means of the names of the Egyptian kings mentioned in the text, and confirmed by the palæographical examination of the characters, and a calendar inscribed on the first page. The result proves this manuscript to have been written 1552 before Christ, being one of the oldest original documents which have come down to our days. It is now in the library of the University of Leipzig, where it is preserved, cut into sheets corresponding with the pages, in glass-frames.[1]

According to Clemens of Alexandria[2] (died about 220 A.D.), and Jamblichus[3] (about 310 A.D.), there existed 42 so-called Hermetic books of the ancient Egyptians, 36 of which contained their philosophical works, and 6 the various branches of the medical art, namely: treatises on surgery, anatomy, therapeutics, diseases in general, ophthalmology and gynæcology.[4] The present work is, without doubt, the treatise on therapeutics, and it betrays an astonishing knowledge of a great variety of remedies. Evidently at the time of its composition, medical art was in a flourishing condition in Egypt as well as in Syria.[5] We know that the great universities of the Egyptians were at Memphis, Heliopolis,[6] Thebes, and Saïs and Chemnu, at all of which places the medical art was studied and taught, and where important consultations on difficult cases were wont to take place. The papyrus shows that in the sixteenth century before our era there were learned men in Egypt, who could make intelligent observations of disease, combine complicated recipes, and use them with judgment. The author even mentions remedies which have come down from *ancient* times, as e. g., a species of collyrium originated by Xui, an *ancient* physician, or when he discusses the antiquity of the use of the teqem-tree.[7] Although incantations and invocations play a considerable rôle in the treatment of diseases, because priestly physicians could not do well without them,[8] still there is an entire absence of galimatias or gibberish. In those ancient times the magic art was strictly interdicted, and even

[1] The title of the work, translated from the German is: *Papyrus Ebers, The Hermetic Book on the Materia Medica of the Ancient Egyptians, in Hieratic Writing. Edited, with indices, and introduction, by George Ebers. With hieroglyphic-latin glossary, by Ludwig Stern, under the patronage of the Roy. Bureau of Education of Saxony.* Leipzig, 1875; 2 vols., folio. A translation and commentary are promised by the editor. In the original, although it is a continuous roll, the text is nevertheless divided into sections, corresponding to what we may call pages, numbering 110, each of 21 or 22 lines.

[2] *Stromata, ed. Potter*, VI., p. 758, § 634.

[3] *Myster.* 8, 1 sqq.

[4] The priests or pastophores ("carriers of the sacred symbols and vessels," mentioned also in the body of the work) had to commit all these works to memory *by oral instruction only*, exactly like the brahmans of India, who are required to study and learn the Vedas only by oral teaching; and although the number of those who adhere to the old tenets is gradually dying out, still there are found numbers of sacred scholars, or bhattâchâryas, who have all the holy writings by heart.

[5] On page 68, line 8 of the text, there is mentioned a remedy for the eyes, "*according to the authority of a Senate of Byblos.*" Byblos, the *Egyptian* name of which is Kepni, *Heb.* Gebal, was a city of Syria, now Jebeil, of which a singular legend is related by Lucian de Syr. dea, 7.

[6] Strabo (died 24 B. C.) yet "saw the large house at Heliopolis, in which the priests, skilled in science and astronomy, had once dwelled," and he adds, that "at his time the science, as well as the priests, were things of the past" (17, 806).

[7] Other allusions to older writings are: pg. 75, 12: "*Pay well attention. This is a genuine remedy, found during a search in the temple of Un-nefr*" (= Osiris-Agathodæmon); pg. 103, 1: "*Remedy to cure all bodily pains, as it was found in writings under the feet of the Anubis-statue at Chesem. It was brought to His Majesty of Upper and Lower Egypt, Usaphais, the just.*"

[8] The same is true of the ancient Hindus, one of whose sacred books, the *Atharvaveda*, is full of incantations for the removal of diseases (chiefly the "takman," presumably an eruptive fever), and is likewise full of medical and therapeutical allusions, on which I will endeavor to give information hereafter.

Rameses III. yet punished alchemists and magicians with death. The art of healing was communicated by the Egyptians and Phœnicians to the Greeks,[9] among whom it was held in the highest esteem, even in the earliest times, when it yet stood in close connection to Vaticination (Mantic); it was always considered as an occupation worthy of a freeman, while among the Romans it often descended into the hands of slaves. In many Greek states the physicians received public salaries,[10] in others they practised for fees,[11] sometimes paid in advance,[12] to cover expenses of pharmaceutical preparations, which they themselves procured. Self-medication, a most common practice with the Romans, was entirely rejected by the Greeks, who permitted only those to practise who had studied under a reputable teacher, and we find even traces of suits of malpractice. Later, a number of specialists made their appearance as oculists, aurists, dentists, surgeons, and even female gynæcologists.[13] But in after-Christian times the black art began to make inroads into the science, gradually corrupting and almost obliterating it.

Although the present papyrus was found near the necropolis ("City of the Dead") of Thebes, it was certainly written in lower Egypt; as was also another more recent medical papyrus, now in the possession of the Berlin Museum, which was found in an earthen vessel at Saqqarah, that is, the necropolis of Memphis. In this connection it may be interesting to mention that in addition to these two, there is another medical papyrus of 15 pages in the Berlin Museum, one in the Museum in Leyden,[14] one in the British Museum,[15] one in the Musée de Louvre at Paris, one in the Viceroyal Museum at Bulaq, and one in the Museum in Turin,[16] besides a medical work in Coptic, written about 900 A.D., but composed much earlier, which is evidently derived from a work similar to the Papyrus Ebers.[17] Finally, L. Stern discovered in the library of the Khedive at Darb el Gamamiz a copy of the Arabic medical work of Abu Sahl Isa ibn Yahya el-Mesihi, a converted Copt, the end of which is almost a verbal translation of a portion of the Papyrus Ebers, and is entitled, "Chapter on Remedies," and mentions a hermetic text.

I will now proceed to give a summary of the contents of the papyrus, followed by an account of the weights and measures and the materia medica of the work.

1. *Therapeutics:*—Mention is made of various Purgatives; Diuretics; Anthelmintics; Antilithics; Tonics; Abortives (treatment per vaginam). Remedies for incontinence of urine; strangury; fistula; hæmorrhoids; do. for diseases of stomach and heart; do. for hemicrania; diarrhœa; infantile diarrhœa; lymphatic swelling in groins and throat; stricture; itch; conjunctivitis; lippitudo; albugo corneæ; cataract (treatment: dried children's fæces); "smaragd-disease" (glaucoma?); blindness; gerontoxon (arcus senilis); "crocodile-disease" (probably pterygion[18]). Remedies for removing granulations, and to contract the pupil; do. for inflamed eyes, to be used at various seasons of the year.[19] Remedies for tumors in nose; do. to prevent gray hairs and falling out of hairs; to make hair grow—even on a bald head and on a cicatrix;[20] to make it fall out; remedies for cancer: gangrene; for healing wounds and wales; for various eruptions (leprosy; herpes?—on page 27, 16, there is also mentioned a pustular eruption, which Prof. Ebers thinks may have been *small-pox*); for boils, toothache, dental abscesses, erysipelas, swelled legs, lameness, footsweat, shaking palsy, diseased bones, and summer or Nile-fever. Remedies to alter the color of the skin, to give a smooth complexion and to remove wrinkles: do. for prurigo, prolapsus uteri and prolapsus vaginæ, excoriations and condylomata in vulva, pruritus, diseased milk, puerperal fever and amenorrhœa; do. for deafness and running of ears. Instructions how to bandage wounds, how to treat dental diseases and how to extract the child from the womb; methods of expelling urinary calculi, and how to remove them by operation from the male or female, or how to destroy them in the body; how to remove inflamed tumors from the loins of persons suffering from urinary diseases; and means for destroying fleas, lice, serpents, rats, mice, lizards, etc., etc.

2. *Anatomy.*—The work contains proof that the ancient Egyptians were tolerably well versed in superficial anatomy, for nearly all parts of the human frame are mentioned, as well as the large viscera; besides there is mention made of bile, urine, semen, saliva, footsweat, lymph, calculi, moles, etc. The functions of many important organs were however unknown to them, and I am inclined to believe that actual opportunities for studying anatomy offered themselves but rarely, for nerves, arteries and veins are frequently confounded together, as for instance in this passage (pg. 99, 1):

"The secret book of the physician: The science of the movement of the heart: from it go vessels into the whole body. In regard to these the priestly physician Neb-Secht maintains, that 4 go into the cheeks (2 giving sap, 2 blood), 4 into the interior of the temples, 4 each into the head, nose, ears,[21] intestines, spleen, liver and buttocks, 2 each into the kidneys, bladder (?) and testicles, and 6 into each arm and leg. Wherever he may lay his finger, upon any part of the body, he touches the heart."

3. *Weights and Measures*—Weights are indicated by

---

[9] This fact, well known from the admission of the ancients themselves, has obtained further and conclusive proof by comparison of the contents of the medical works of the Egyptian and Greek physicians; a number of technical terms, names of remedies and modes of treatment being clearly derived from the Egyptian text books. In Galen's days (born 131 A.D.) the science had already much degenerated.

[10] See *Strabo*, 4.181; *Diodor*, 12.3.—About 540, B.C., *Democedes*, a celebrated physician of Croton, received as high a salary as a talent of silver ($1,926); when called to Athens, he received 100 minas ($1,710), until Polycrates, of Samos, gave him two talents (Herod. 3, 131).

[11] Among the Romans the usual average compensation for a medical visit or consultation was 1 *nummus* (about 29 cents); but we read of fees as high as $10,000 (Plin. hist. nat. 29, 1, 10, and 22); and the court-physicians of the Emperors had salaries of about $15,000, and one even of $20,000.

[12] In some portions of China the custom prevails to pay a physician a regular monthly or weekly salary, which he receives as long as the members of the family, for or from whom he receives it, are in health. During their sickness the salary is stopped, until recovery has taken place. A truly Chinese bargain!

[13] In Athens slaves and women were not allowed to practice medicine. Later, however, when a woman, Agnodice, had been discovered exercising obstetrical practice in man's attire, for which she was to have been punished, the women of Athens took up her cause, and succeeded to have the laws so altered as to permit females to practice. (See *Hyg.*, 274.)

[14] The Greek text of this was published by C. Leemans. See also *Reuvens* in his "*Lettres à M. Letronne.*" This is very valuable on account of the many names of plants and minerals which it contains.

[15] This is a palimpsest dating from the 18th dynasty, 7 inches wide and 8 feet long, containing considerable gal matias.

[16] Contains a magic text interlarded with medical chapters.

[17] Instead of the Egyptian names of Gods (as *Ra*, *Shu*, etc.) there are invoked archangels, among them *Oriel* (Uriel), *Gabriel* (Michael), and *Raphael*.

[18] So-named by the Greeks, on account of its similarity to a finely-reticulated insect-wing, which the head of a crocodile resembles.

[19] The Egyptians have always suffered from many eye diseases. See *Pruner*, *Die Krankheiten des Orients*, page 432.

[20] On page 66, 15 a remedy is quoted, having the following commendatory title: "*Another remedy to cause the hair to grow, invented by Lady Ses, the mother of his august majesty the King of Upper and Lower Egypt, Teta, the just.*"

[21] Page 103, 15: "*To the right ear lead two nerves, by which the spirit of life enters; to the left ear lead two nerves, by which the spirit of death enters.*"

numbers surmounted by a dot. The numbers occurring in this manner are 4, 16, 32, 64, as fractions of 1. The unit of weight finds its equivalent in the later Arabic *dirhem*,[22] or drachm, which name, in the absence of another, has been chosen by Prof. Ebers to denote it.

The unit of measure is the *tenat*, equal to 0.6 of a litre. Another is *hemu* (*Heb. hin*), equal to 0.465 litre. There are special signs to denote these, as well as to express fractions such as $\frac{1}{2}$, $\frac{1}{4}$ and $\frac{1}{8}$. $\frac{3}{8}$ is expressed by putting side by side the fractions $\frac{1}{2}$ & $\frac{1}{8}$; $\frac{1}{8}+\frac{1}{8}=\frac{2}{8}$; $\frac{1}{8}+\frac{1}{4}=\frac{3}{8}$; $\frac{1}{4}+\frac{1}{2}=\frac{3}{4}$. A perpendicular line opposite the several ingredients of a mixture denotes equal parts.

4. *Materia Medica.—a. Minerals.*—Many metals or metallic compounds are mentioned, but not all are recognizable.[23] We find mention made of sea-salt, nitre, charcoal, lead, bronze, antimony,[24] copper,[25] lapis lazuli, sapphire.

b. Animals.—The following are mentioned as furnishing material for certain remedies and preparations: crocodile (2 varieties),[26] ass, bee, beetles and flies, stag, buffalo, roe (Capra hircus), hedgehog, lizard, cow, ox, wild cat, swallow, camel, pig, ram, greyhound (Canis vertagus, imported from Abyssinia), hippopotamus, bat, goose, tortoise. In addition, the following are mentioned as nuisances: flea, louse, rat, mouse, dog-tick, and various worms, chiefly the tape-worm (Tænia solium).[27]

c. Plants.—*Acacia vera* Willd. (*Egypt. sentet*, now *sont*), acacia.—*Acorus Calamus* L., sweet flag.—*Hæmatoxylon Campechianum* (?) Lour., logwood.—*Artemisia* (probably *Pontica* L.), Roman wormwood[29].—*Balsamodendron Myrrha* Nees., myrrh[30].—*Boswellia serrata* Roxb., frankincense tree[31].—*Cicer arietinum* L., chickpea[32].—*Cocos fusiformis* Willd. (*Ebenus Æthiopica*), black ebony tree[33].—*Coriandrum sativum* L., coriander.—*Crocus sativus* L. and other species), saffron[34].—*Andropogon Schœnanthus* L., sweet rush.—*Cucumis melo* L., melon.—*Cuminum Cyminum* L., cumin[35].—*Citrus medica* Risso, citron (the fruit).—*Ceratonia Siliqua* L., St. John's bread[36].—*Cyperus comosus* L., hairy rush[37].—*Ficus sycamorus* L., sycamore fig-tree[38].—*Hyacinthus* (nonscriptus? L.), hyacinth[39].—*Hyoscyamus niger* L., henbane.—*Hyphæne cucifera* Persoon (*H. Thebaica* Gaert. *Cucifera Thebaica* Delile), ginger-bread-tree, dum palm[40].—*Juniperus communis* L., common juniper, and *J. oxycedrus* L., Spanish juniper[41].—*Lactuca sativa* L., lettuce[42].—*Linum usitatissimum* L., flax.—*Mandragora officinalis* Willd., mandrake. Abraun (fruit and root)[43].—*Morus nigra* L., mulberry[44].—*Nymphæa lotus* L., lotus[45].—*Olea Europæa* L., olive tree[46].—*Parietaria officinalis* L., helsine, wall-pellitory.—*Phœnix dactylifera* L., date tree[47].—*Pinus Cedrus* L., Cedar of Lebanon[48].—*Pistacia Lentiscus* L., mastich tree[49].—*Pistacia Terebinthus* L., turpentine tree[50].—*Punica granatum* L., pomegranate.—*Ricinus communis* L., castor-oil-plant[51].—*Salix* (species?), willow.—*Sesamum orientale* L., gin-

[22] The Arabic *dirhem* or drachm equals 48 grains, and is even now divided into 64 parts, called *kamhah* (wheat grains), four of which make a *kirat*. Now as 1.61 dirhem or 1 kamhah is frequently prescribed of substances, where evidently a larger quantity is intended, Prof. Ebers conjectures that the unit is really not the drachm, but the *didrachm*. This supposition is strengthened by the fact that the corresponding equivalent in *Coptic* (which is a descendant of the ancient Egyptian), namely κιτε or κατε, may denote either weight; and also, because the sign for $\frac{1}{2}$ *tenat*, which was originally a liquid measure, occurs likewise as weight, namely equal to one-half of our unit, which sign has come down to us in nearly the same shape (𝄾), and with nearly the same value as the *full weight of a Greek dirhem*.

[23] Compare *Lepsius on Metals in Egyptian Inscriptions, in Abh. d. Akad. d. Wiss. in Berlin*, 1851, 77, 126.

[24] The Egyptians used black native sulphide of antimony as a collyrium, and it is even yet employed by the women of Egypt to color their eyelids. The *Egyptian* name of antimony is mestem or stem, *Coptic* σθημ or στημι-stibium, στιμμι. We possess several recipes for preparing these collyria, which were usually kept in small boxes, often partitioned off to hold several kinds, like one preserved in the Paris Museum, being no doubt identical with what *Pliny (hist. nat.* 13, 5, 11) calls *scrinium antiparum*, the first of which was found by Alexander among Darius' baggage.

[25] According to *Lepsius* this is not copper, but *electrum*, τὸ ἤλεκτρον. *Le Page Renouf* says it is *æs Cyprium* or *ustum*, χαλκὸς κεκαυμένος, used for destroying proud flesh.

[26] One is called *utu*, the other *mseh*, *Arab. al tamsah*, by metathesis χάμψα *Herod.* 2, 69.

[27] This is supposed to be this variety, from the fact that *Botryocephalus latus* or *Tænia lata*, which are common in Switzerland and Russia, are very rare in the southern countries of Europe and in the East.

[28] The identity of this is not quite certain. It was an odoriferous herb brought from Arabia, and very likely was *zizer wood*, a species of aroma highly valued by the orientals. On its use see *Dioscor.* 1, 21.

[29] Possibly *Art. Cina* Wikst., *Arab. shaanah* ("the green").

[30] *Plut. de Isid. et Osir.* 81-81: "At noon-meal the Egyptians fumigate with myrrh."

[31] The resin is the part used (*olibanum*.)

[32] *Greek* ἐρεβίνθος (modern ῥεβίθια); cf. *Galen. de alim. fac.* 1, 22. *Athen. Deipn.* 2, 41.

[33] *Ebony*, derived from this source, as well as from *Diospyros mespiloides* Roxb., and an inferior kind, viz.: *Anthyllis Cretica* L. (*Theophr. hist. pl.* 4, 1, 6) were used chiefly as astringents; cf. *Dioscor.* 1, 29.

[34] Used in a variety of ways, in infusion, decoction, in mixtures, and in salves. *Dioscor.* 1, 25-26 says, that the saffron-paste, κροκόμαγμα, is made from saffron-salve, κρόκινον μύρον, by expressing the aromatic parts and shaping them into forms.

[35] *Hippocrates* called the Ethiopian Cuminum, "*the royal*" (Βασιλικόν), after this he placed the Egyptian, and then the other.—*Diosc.* 3, 61.

[36] *Egypt.* nan, *Arab.* charrub=Carob tree, was very much used. *Theoph.* 4, 2, 4, says that it does not grow in Egypt, and was wrongly called at his time "Egyptian fig." *Galen. de al. fac.*, 2, 23, pronounces it as not being wholesome food, and says it should not be imported.

[37] This is the *Greek* σάρι or σαρῖν (*Egypt.* sara'), which, according to *Theophrastus* (*hist. pl.* 4, 8, 5), grows in swampy places inundated by the Nile.

[38] All species of *Ficus* were held in great esteem by the ancients; the wood is almost indestructible, and every portion of the tree is of value. *Ficus Bengalensis* L. (*Ficus Indica* Roxb.), the banyan tree, yields a white glutinous juice, used as an application to the cracks on the soles of the feet; see *Ainslie, Mat. Med.* II., 10.—*Ficus oppositifolia* Roxb. and *F. polycarpa* Roxb. are valuable emetics (fruit, seeds, and bark).—*Ficus religiosa* L. plays an important part in Hindu religious ceremonies, and occurs already in the Vedas (*Rigv.* 1, 135, 8, etc., *Atharvav.* 3, 6, 1, etc.).—On the medical uses of *Ficus carica* L. among the Hindus, see *L. Da Costa* in *Cuchyne's Ind. Med. Journal*, 1837, 731.

[39] *Egypt.* sesen, *Heb.* shoshan, *Arab.* susan: this, however, is supposed to be rather *Nymphæa lotus*.

[40] Κουκοφόροι (*Theoph.* 4, 27). Cf. *Alex. Ziegler, Reise im Orient*, Leipzig, 1855).

[41] The fruit, tops, and oil were used. The Greeks enumerate in their recipes of κῦφι two species (ἀκενθίδες δυο, *Dioscor.* 1, 103), the *large* and the *small*; the former is *oxycedrus*, the latter *communis*.

[42] Lettuce (ἐρίδαξ) was used by the Greeks as a soporific (*Hippocr. de Morb.* 4, 2; *Celsus* 2, 32; *Pallad.* 2, 14; *Martial*, 13, 11), but the species *virosa* seems to have been the one, the juice of which, mixed with opium (μηκώνιον), was used for this purpose. (*Dioscor.* 2, 165).

[43] The root is split, and has been compared to human legs, from which circumstance originated many superstitious uses. *Columella* (10, 19) calls it "half man, half plant." See *Paul Ægin. ed. Fr. Adams*, II., p. 219.

[44] The fruit, bark of root, leaves, and juice of root were used by the ancients. The fruit was called "bread" by the Egyptians. It was used against fevers, by applying it with scented oil upon the region of the stomach (*Athen. Deip.* 2, 51). The same authority observes that the fruit is sessile, without a stalk (φέρει δὲ τὸν καρπὸν ἢ ἀγίστια συκάμινος ἀπὸ τοῦ ξύλου καὶ οὐκ ἀπὸ τῶν ἐπικαρπίων, *Ibid.*).

[45] This is according to *Unger, Bot. Streifzuge* 4, 122, the plant shoshan (see note 39). The Egyptians collected it, dried it in the sun, comminuted the poppy-like body within the flowers, and baked bread of it (*Herod.* 2, 92; *Theophr.* 4, 8, 9). *Diodor. Sic.* (1, 10, 34, 3) says, that they have learnt the use of edible fruits and of lotus from Isis and the old King Menas.

[46] The fruit and oil were used.

[47] The fruit alone is used. An infusion of it yields by fermentation a species of wine, which is yet much used in Nubia, where it forms a general every-day stimulant.

[48] It is frequently doubtful whether by the oil is meant oil of Juniper or oil of Pinus Cedrus.

[49] *Egypt.* tenten, *Greek* σχῖνος. Forms an ingredient in kyphi. *Palladius* 2, 20, mentions an oleum lentiscinum=λέντισκον σχῖνον of *Dioscor* 1, 50, which is prepared from the ripe seed by extraction with boiling water.

[50] *Dioscor.* 1, 50, 1, 91, mentions an oil, τερεβινθινον ἔλαιον, made like mastich oil (see note 49).

[51] Seeds and oil were used. *Egypt.* gaga, *Copt.* κικι, *Greek* κροτων, *Hebr.* kikayon. According to *Dioscorides* (1, 38, 4, 164) the Egyptians do not prepare the oil by boiling the seeds with water, but by expressing the crushed seeds.

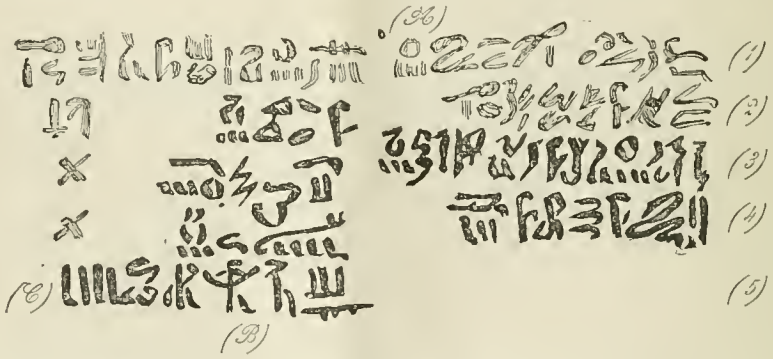
gelly, benne[52].—*Sorghum vulgare* Willd., Turkey millet.—*Tamarix Africana* Desf. and *T. articulata* Vahl, tamarisc.—*Trigonella fœnum Græcum* L., fenugreek[53].—*Triticum spelta* L., spelt, and *T. vulgare* Vill., wheat.—*Vitex Agnus Castus* L., agnus castus.

d. Miscellaneous Remedies.—A great variety of remedies occur, which it was difficult to classify otherwise, and which are therefore placed here together. We find mentioned: decomposing or purulent blood (for external use); 27 various oils, nine of which were considered sacred[54]; beer which had ceased to ferment; vinegar[55]; crude honey; wine; milk; spring-water; dried blood of various animals; sour and sweet grapes; various flowers; tortoise shell; fermented dough; yeast; bread, simple, or mixed with aromatic seeds, or sweetened; wax; eggs; chaff; human brains, semen, urine, fæces and menstrual fluid[56]; water which has been used for washing the genitals; fluid pressed from pigs' eyes; the genitals of cats (most of the last named for external applications only); and a species of lint for surgical dressings.

5. *Pharmacy.*—Although many passages of the papyrus are as yet not fully understood, owing to the occurrence of doubtful technical terms, or names of unidentified plants, animals and minerals, we still find a number of pharmaceutical acquaintances, such as globule, pill, granule, cataplasm, mixture, ointment, aromatic ointment and pomade, collyrium, pastille, clyster, mortars and capsules. A large number of recipes and formulæ are given in the text, as for instance: *For colic-pains: Cumin* $\frac{1}{64}$ 3, *goose-fat* $\frac{1}{8}$ 3, *milk* 1 tenat. *As a diuretic: Honey, St. John's bread, Agnus Castus seeds, of each, equal parts* (1 3). One of the most interesting is the recipe for the *Kyphi*[57], which was a celebrated mixture used by the Egyptians for fumigations, as medicine, and in embalming, the composition of which is given on page 98 of the papyrus as follows:

"*Preparation of Kyphi, to make agreeable the odor of the house or of dresses:*

"*Myrrh (dry), juniper (berries), olibanum, mastix (twigs), fenugreek (seeds), raisins (*? *temten*), and three



THE ABOVE TRANSLATED INTO THE HIEROGLYPHIC CHARACTER.

Medicine for opening the bowels
Beginning of the Book of the Medicine (1)
Milk
1/3 hena
To cure the sickness of the bowels (2)
Nekaut (?) Pulverized 1/4 drachme
(seeds of the) She hut plant rubbed up with Vinegar (3)
Honey
1/4 drachme
To be drunk by the patient. (4)
Cook pour out, eat for four days. (5)

[52] Oil of sesame was used quite frequently. The *Egyptian* term is semsemt, *Copt.* σεμσημ, *Arab.* simsim.

[53] The seeds. This plant has a variety of names: *Egypt.* sabt. *Greek* βουκερας (oxhorn), αιγόκερας (ram's horn, whence the *German* appellation Bockshorn), and τῆλις (*Modern Greek* τῆλυ).

[54] These are in frequent use, often combined with honey, corresponding to the oil-honey or ἐλαιόμελι mentioned by *Dioscor.* 1, 37. We also find "oil made two days before," and "winterstrained oil."

[55] The Egyptians were celebrated for their excellent vinegar; according to *Athen. Deip.* 2, 67, they prepared it from grapes, raisins and dried figs.

[56] Excrementitious matter has been used by many nations for remedial purposes. Semen virile and sanguis menstrualis even by the Arabs, according to *Abu Hurairah al Saffuri*. A very full account of excrementitious medicine among the Hindus may be found in *Pharmac. Journ. and Trans. Nov.* 1875, *page* 364.

other unrecognizable ingredients. *Mix them together and put them to the fire* (namely to burn them; may also mean 'and set fire to them.') *For women it is to be prepared otherwise; namely, it is to be boiled with honey, mixed, and formed into globules; they fumigate*

[57] Kyphi is mentioned by *Hieron. in Jovin.* 2, 8. *Scribon. Larg. compos.* 70. *Galen* (several times), and *Plutarch* (*de Isid. et Osir.* 81) mentions the following as ingredients of κῦφι, namely: lemongrass (*Juncus odoratus*), aspalathus (*Cytisus Græcus*), shrubby hartwort (*Bupleurum fruticosum*), mastich (*Pistacia lentiscus*), bitumen (probably means *Chios turpentine*), swamp-grass, (*Ulva conferva*), sorrel (*Rumex*–), the small and large Juniper, (see note 41,) cardamom (*Amomum Cardamomum*), sweet-flag (*Acorus Calamus*).

with them, and also use them as pastilles to make agreeable the odor of the mouth"."

In conclusion we annex a fac-simile copy of portion of a page of the papyrus, with its translation. The lightly-shaded portions of the copy are in the original written in red; the others in black. The reader may compare the lines of hieratic writing of the original, which reads from right to left, with the translation in hieroglyphics, of which the other form of script is an abbreviation, and which are read from left to right.

NOTES ON THE PATHOLOGY AND TREATMENT OF SOME FORMS OF HYSTERICAL DISORDERS.

By EUGENE DUPUY, M.D. (Univ. Paris.)

NEW YORK.

If hysteria in some of its severe paralytic forms is very untractable, it is by no means unamenable to therapeutic agents. It is well known that some cases of contracture, more frequently of the lower limbs, will, after long duration, simulate all kinds of malformations, and when the muscles have undergone wasting, leave, as a sequel, a useless limb.

But what is the nature of the disease—or, in order to be in accordance with the majority of contemporary pathologists who think that every disease must, in every case, have their *fons et origo* in the same organ—where is the seat of the malady? If a very great number of high authorities see a connection between abnormal states of the female generative organs and the development of hysteria, many others, invested by common consent with just as high authority, deny any such connection. I shall simply state, that diseases of almost every viscus have been traced as the starting cause of hysteria; and that some of its severe forms—contracture, paralysis and wasting—have been observed in children before the age of puberty, and in women after the critical period. A theory which is now gaining ground in France, and which does not lack ingenuity, originated with Professor Charcot. He, after carefully comparing the phenomena of hemianæsthesia, hemiplegia, etc., etc., usually associated with certain forms of hysteria and similar symptoms, which, according to him, are always met with in destructive diseases of that part of the middle encephalon called internal capsule—believes that that part of the cerebral organs is the seat of hysteria in its hemiplegic form at least. I would certainly adopt that theory. Elsewhere I have shown this idea to be somewhat fallacious * (for it is always safe to sail under the same wind with so eminent a teacher as Prof. Charcot), provided the internal capsule were a nerve centre instead of being merely a tract of sensitive and motor fibres, identical with the tract of the spinal cord, is devoted merely to sensito motorial conductions. The study of cases of lesions of the pons Varolii, both in male and female subjects, caused by most diverse diseases, and in which I have very often observed hysterical symptoms, cause me to doubt. These symptoms have been well studied by my friend Dr. E. C. Seguin. He thinks that they depend upon various lesions, more especially of the right hemisphere of the brain, a view put forward by De Fleury, of Bordeaux, in his work on the Comparative Dynamics of the Cerebral Hemispheres, some years since. This opinion, and the assertion that some hysterical symptoms have been observed in diseases of the pons, by Bastian, of London, in his treatise on Paralysis from Brain Diseases, together with a pretty numerous series of experiments on dogs and cats, permit me, I believe, to state, that very likely, hysterical phenomena are dependent upon the abnormal state of either lateral portion of the upper part of the pons Varolii.* I may as well state here that the nerve centres of the pons are perhaps merely passive in the process, and only become organically implicated when we already find contractures and paralyses with atrophy of muscular tissue and the consequent deformities. I have satisfied myself that the origin of the trouble is a vascular one of the nervous centres, an abnormal condition of the so-called sympathetic nerves. The origin of the latter, according to classical authorities, is in the pons; but I believe it is all along the spinal cord and base of the brain, as shown by Vulpian lately, and as taught for now more than twenty years by Brown-Séquard. But, unlike the above named eminent physiologists, I think it probable that the vaso-motor nerves, instead of originating in the axis of gray matter of the spinal cord and pons, penetrate into it, and instead of proceeding from those centres together with the other nerves as they come out, and as Bernard has tried to establish for the so-called cerebral nerves, they only join the nerves of motion and of common and special sensation at their exit from the cerebral and spinal mass, and at the point where they receive their sheathing from the pia mater. For the trigeminus nerve, at least, this point is beyond contest, both experimentally and anatomically. One of the first workers with the microscope in the field of anatomy of the nervous centres, Hanover, has as far back as 1844, most beautifully figured the fibres, cells and small ganglia on the tract, and chiefly on the ganglion of Gasser of the trigeminus. Moreover, Rainey, in a paper published in the *Transactions Med. Chirurg. Society of London*, 1844, states that the arachnoid is the centre from which arise the vascular nerves.†

If after the removal of the whole cerebral hemispheres and ganglia, except the pons, sensations in warm-blooded animals still persist, as proved by the experiments of Vulpian, and more recently of Onimus, Lepine, Brown-Séquard and others; it appears to me legitimate enough to conclude that the vascular nervous centres, which are most numerous around the pons, are altered either directly or indirectly through peripheral sensory fibres. The nature, seat, and duration of any given irritation will determine the variety of diseased manifestations. In this connection I may call attention to the very able pamphlet of my learned friend, Dr. Lepine, of Paris, in which he has reported cases of hemiplegia and other interesting phenomena dependent upon diseases of the lungs, and some very curious and suggestive experiments of my eminent friend and teacher, Brown-Séquard, showing various effects exercised by mere pricks of the lungs and other small thoracic viscera upon the pupil of the eye. These are very interesting facts, which go to support the theory that alterations of the abdominal and thoracic viscera do have a very strong "retentissement" on the vascular centres. Well-known phenomena of hemianæsthesia and anæmia of the skin, or contractures

* The Egyptian women are noted, even to this day, for their bad habit of chewing onions and garlic.

* Thèse Inaugurale, Paris, 1853.

* Brown-Séquard has shown me, some months ago in Paris, dogs upon which he had burnt some part of the convolutions, and found, not only paralysis on the same side, but even paraplegia, alone and hemi-paraplegia. This will dispose of the objection that might be raised that disease of the pons cannot give rise to symptoms simulating paralysis or contracture of the lower limb alone, as in hysteria.

† For more on the subject of vaso-motor centres, see my paper in C. R. de la Soc de Biol., Gazette Méd. de Paris, p. 576 and p. 601. Consult also Rochefontaine, Id., p. 565 and p. 648.

followed by paralysis, deformities, etc., which may become permanent at the end and present a faithful picture of amyotrophic sclerosis (Charcot), and of coxalgia (Brodie, Verneuil, etc.), and even of club-foot. As my intention is only to deal with that form of hysteria which sometimes does ultimately verge in permanent deformities and paralysis through wasting, I shall dismiss the other aspects, however interesting here.

The diagnosis of the disease is not, as a rule, a very difficult one, except perhaps, when it attacks very young males and females; in which cases it may be mistaken for coxalgia, so-called idiopathic contractures following convulsions, wasting of infantile paralysis, club-foot dependent upon organic disease of the spinal cord, etc. But if it is sometimes difficult, when the deformities have been long standing, to discover what is their origin, it is, however, not absolutely beyond our means; careful consideration of the habits of the little patients, and of the onset of the disease will help us a good deal to clear the obscurity; but of this, more hereafter. When the paralysis occupies the upper limb or one side of the body in adult patients, it is much more often the left side. Sometimes the minor symptoms will almost give rise to the suspicion that hemorrhage has taken place in the brain; but the state of the pupils which are dilated in hysteria, and slightly respond to light; the non-deviation of the tongue, the non-alteration of temperature, or its lowering below the normal degree, the loss in a more or less degree of sensation in the paralysed parts; will help us to come to a correct differential diagnosis. When contractures are present it will be easily seen that we have not to deal with hemorrhage or coarse lesions of the brain, by the fact that if we try to push the extended arm by pressing on the palm of the hand in such a way as if to push the limb behind the shoulders, or perform the same operation on the sole of the foot, pushing the leg in the axis of the trunk, we will detect, particularly if the diseases is of long duration, the peculiar shaking common to every form of sclerosis. This aspect of hysteria, as pointed out by Professor Charcot, is due to secondary fasciculated sclerosis of the lateral column of the spinal cord, which, however, he distinguishes from what he has called amyotrophic sclerosis, by the fact that in the last-named disease the cells of the anterior horn of the spinal cord are primarily affected, while in the hysterical wasting under consideration, the cells become affected only as a consequence. Moreover, in all the hysterical shams, however chronic, of muscle disease, galvanic electricity gives rise, both through nerve and directly, to contraction, which it is well known does not take place in the genuine diseases. If we have to deal with contractures of parts only of muscles of the lower limbs, the diagnosis is sometimes more troublesome. To say nothing of the many means which individual ingenuity can suggest, one at least will always settle the case, provided there has not already been a complete wasting of muscles; and that is inhalations of ether or chloroform, and perhaps nitrite of amyl, but chiefly the exhibition of chloral hydrate, in full doses. Indeed by that means it is almost always sure that we shall discover if we are dealing with hysterical mimics of organic diseases of the nervous centres.

In every case, of course, it is most important to know the history of the disease; and if we have to treat children, one of the first points to make clear is, whether they are not addicted to onanism or irritative practices upon the genitals. I have lately seen in Paris a girl eleven years old, not yet menstruated, who presented a deformity amounting to atrophy of some muscles of the leg and club-foot, which could be ascribed to no other cause than that stated above. She is actually highly hysterical.

But it is not enough to try to find out what the characters and features of hysteria sometimes are; by far the most interesting point is the treatment. If in very great number of cases of hysteria the physician has to resort, through failure with all else, to so-called moral treatment, I must say, that in the forms of the disease of which I have been speaking, he will run great risk of allowing permanent impairment of some limb of the patient. Moreover, if the physiological process of the disease be such as I have tried to establish, it is not unreasonable to resort to therapeutical agents, which former experience has taught to be of service in similar conditions. I have sometimes been lucky enough to relieve a few patients suffering from paralysis of motion, and sensation by the use of strychnia, steam-bath, massage, and generous diet. In a long standing case, I tried the actual cautery, applied on the nape of the neck, but perhaps the "emotion" of the patient did all the curative work in this instance. When there is contracture, it will be made to disappear by the use of chloral hydrate, exhibited every other night, and steam-bath on the intervening days, the cold douche only to be applied to the head and neck. The spinal hot-water bag is more efficacious in some cases where only the lower limbs are implicated. Of course, the continuous current of electricity has to be employed; but just as with faradic electricity, it will be found to be of little avail except when directed against the wasting of the muscles. By far the most effective treatment, and chiefly so when there is the shaking, indicating sclerosis of Charcot—consists in large doses of strychnia, and alternately of iodide of potassium in not more than four or five grain doses of the latter, and the application of the actual cautery. I have employed this latter agent, after the manner adopted by Brown-Séquard. It must be used every other day, and in order to be able to do that and also to assure success, the iron must be heated to whiteness, and only allowed to touch the skin, which then peels off just as if scratched very slightly by the nail—and the touches must embrace a pretty large surface in length—on the two sides of the spinal processes.

We must not forget, however, that in some instances of pretty frequent occurrence, all the symptoms described in this lecture will vanish on a sudden with the accompanying circumstances, and phenomena generally described in cases of miraculous cures, but which are also daily met with in practice. I need not say, in dismissing this subject of hysteria, that all those therapeutical means will be found only of temporary efficiency, if the primary cause of the disease is not got rid of, whether it be seated in the genitals, the reproductive organs, the viscera, and the nerves or nervous centres.

LIVING LARVÆ IN THE EAR.

By DAVID WEBSTER, M.D.,

OF NEW YORK.

I HAVE seen two cases of living larvæ in the ear; the first (Mr. G. W. G., æt. 24), I saw at the office of Dr. C. R. Agnew, in the summer of 1874. He gave a history of chronic suppuration of both middle ears, which commenced during an attack of scarlatina, at the age of four. This discharge had ceased at the

age of twelve, and his general health immediately began to suffer, but was restored to its normal condition when the discharge re-established itself, after a cessation of about three months. This patient was evidently a firm believer in the exploded theory "that it is dangerous to stop the discharge from an ulcerated ear." Although the discharge had for many years been very offensive, he had done nothing for it until a few days before I saw him, when his left ear had become painful, and affected with an intolerable roaring. He had then caused it to be syringed with warm water, when, to his great horror, ten or fifteen little white worms were washed out of the ear. The syringing had been frequently repeated, but the pain and noise continued; and, on the morning of the day I saw him, a worm, larger than any before, had been washed out, and there had been some bleeding from the ear.

I found the bottom of the auditory canal covered with offensive pus; the membrana tympani had been mostly swept away; and, coiled up, partly in the tympanic cavity and partly in the external auditory canal, squirming and wriggling about in a very lively manner, was a white maggot. I syringed the creature out with considerable difficulty, as he clung most tenaciously to tissues with which he lay in contact, probably by means of the "strong, but delicate framework, of horny consistency, and two hooks also of a stout, horny structure, articulating with this framework," which Dr. Blake, of Boston, has described.

After assuring myself that I had removed the last of the grubs, I inflated the patient's ears by Politzer's method, and advised the use of an astringent night and morning, after syringing with warm water.

I saw him only once more, nineteen days later. He had suffered no more from pain or tinnitus, and his hearing distance, as measured by the watch, had gone up from three inches to nine inches on the right side, and from half an inch to four inches on the left side. No more larvæ had made their appearance.

The second case I saw at Dr. Agnew's clinic, at the Manhattan Eye and Ear Hospital. This was also a case of suppurative inflammation of the middle ear of many years' standing. The patient complained of pain and roaring, and also thought he felt something wriggling about in his ear. The drum-head and the ossicles had been entirely swept away by ulceration, and the tympanic cavity, on inspection, seemed alive with the squirming little animals. Some of these were dislodged by syringing, and the remainder I stirred up with a little cotton twisted about the end of a dentist's cotton-holder, and afterwards washed them out with the syringe. There were five or six of them.

Dr. Roosa, in his admirable treatise on the ear, says: "The ancient works on aural diseases speak very much of worms in the ear, and of the proper means of removing them. It is probable that these so-called worms were the larvæ of insects, which germinated from eggs deposited in the pus of a chronic suppurative process. Certain is it, that since the habit of cleansing an ear from pus has become a well-recognized duty, the practitioner of the present time sees very little of worms in the ears."

19 EAST THIRTY SIXTH STREET.

MODERN ANÆSTHESIA.—Dr. H. P. STEARNS' article on Modern Anæsthesia, which appeared in a recent number of the MEDICAL RECORD, has been republished in pamphlet form. In this publication some typographical errors which found their way into the original article, have been corrected.

RAPID DIMINUTION OF A REMARKABLY LARGE SPLEEN UNDER THE HYPODERMIC EMPLOYMENT OF ERGOT.

By J. H. MILLER, M.D.,

MOBERLY, MO.

MRS. S., aged 28, married, the mother of three children, of previous good health, was attacked in August last with bilious fever, as she states, recovered, but shortly relapsed, and has since that time been suffering from frequent attacks of intermittent fever of the quotidian type.

Her physician, not having been penetrated with the incandescence of advanced medicine, but a thoroughly stereotyped routinist, put her through on remedies of the most obsolete character; and what her disease had not already done for her, he very effectually accomplished.

On the second day of January I called to see her, and found her in extreme prostration and very anæmic, with dyspepsia, neuralgia, a masked form of intermittent fever, and with a spleen of extraordinary dimensions; so large was it that the whole abdominal cavity, from the extreme left to the middle of the right hypochondrium, and from the umbilicus into the epigastrium, was occupied by its presence.

After improving her general condition by proper alimentation, by tonics, and by stimulants, I addressed my remedies more particularly to the reduction of the size of the spleen, and prescribed for that purpose large doses of quinine, chloride of ammonium and iodine, with iodo-croton liniment externally.

Having failed, after considerable perseverance with these remedies, to elicit a favorable response, I determined to abandon them entirely, and put the therapeutic powers of ergot fairly to the test.

No other remedies were administered except Tinc. gentian, ʒiii., Acidi Hydrocyanic dilut., gtt. xxiv., one teaspoonful thrice daily, for some gastric troubles which seemed to call for special attention.

On the sixth day of February, I made the first hypodermic injection of ergot. I visited her again on the 7th, and made the second injection; and, although I did not find any diminution in the size of the spleen, yet discovered a very sensible change in its character and consistency. On the 8th I made the third injection, and at that visit there was a very perceptible shrinkage. Owing to professional engagements of a different character, I did not visit her on the 9th. On the 10th I made the fourth insertion, and found a very decided diminution in its size; and for four consecutive days I made injections with rapid and marked diminution. On the 14th, it had almost attained its normal size. Thus, from the 6th to the 14th, that enormous spleen had almost entirely disappeared under the hypodermic use of ergot alone. On the 4th of March I called, in order to ascertain if the improvement had been permanent. She met me at the door with a recognition of complaisance and with expressions of profound gratitude. The spleen was normal.

MOBERLY, MO., *March* 8, 1876.

CENTENNIAL MEDICAL COMMISSION.—The number of delegates to be appointed to the above, to represent the Medical Society of the State of New York, is thirty-five. The selection is entrusted to Dr. Thomas F. Rochester, of Buffalo, President of said society.

Progress of Medical Science.

Ovariotomy, with Drainage through the Peritoneal Cavity.—Dr. Olshausen, of Halle, has summarized his experiences in ovariotomy, with especial reference to the use of drainage through Douglas' cul de sac, giving an exhibit of twenty-five cases in which he has operated. He has come to share Sims' former opinion, that the majority of deaths after ovariotomy are due to septicæmia, but thinks that the question of the advisability or not of the use of drainage tubes should be determined by practical experience, and not by theoretical considerations. He discusses the objections to the use of the carbolized spray in the operation; and expresses the opinion that drainage and greater care in preventing septic infection will improve even the admirable figures of Spencer Wells. He gives the details of the operation as he practises it, insisting particularly on numerous antiseptic precautions with carbolic acid. After the removal of the tumor is completed, he makes a puncture from Douglas' cul de sac into the recto-uterine excavation with a trocar of full four-tenths of an inch calibre, and carries a drainage tube of the same size through it, and places it in the superior angle of the wound. He regards the first 48, and, more particularly, the first 24 hours after the operation, as the most important in respect to after-treatment in this method, believing, with Sims, that, during that period, a thin fluid secretion is rapidly produced, having highly septic properties, and that it must be promptly got rid of. To this end, he recommends syringing out the tube with a warm salicylic acid solution every hour or two hours during the first day. He generally removes the drainage tube about the twelfth day. The thermometer generally indicates, by the third day, what is to be the fate of the patient. Of the twenty-five cases which he reports, the last fifteen were treated with the drainage tubes. Of the first ten cases two recovered; of the last fifteen, eleven. He does not, however, claim the whole of the improvement for the drainage, but attributes it to better surroundings of the patients—greater cleanliness, and especially thorough disinfectant measures, and to his own increased skill. He believes, however, with Nussbaum, that drainage has saved many cases that would otherwise have rapidly succumbed.—*Berl. Klin. Woch.*, March 6 and 13, 1876.

The Inoculability of Relapsing Fever.—Dr. Motschutkoffsky, of Odessa, has been experimenting for several years with inoculations upon man and animals with the matter of typhus, typhoid, and relapsing fevers, and was successful in the case of the last disease only, and in the human subject. He succeeded only by the use of the blood, taken during a paroxysm of fever, and it made no difference whether it contained spirilla or not. The disease thus induced differed in no respect whatever from that due to other causes, nor was any other form of fever ever developed from inoculations of the blood of relapsing fever. The period of incubation was between five and eight days. Blood kept hermetically sealed for two days in a capillary tube yielded positive results, as did also blood diluted in equal parts with a watery one per cent. solution of muriate of quinine, but when diluted with the one-tenth part of spirit the results were negative.—*Centralbl. f. d. Med. Wiss.*, March 11, 1876.

Typhoid Fever in a Child, with Rupture of the Spleen.—Dr. Wittmann, from observations in the Children's Hospital at Pesth, declares that in all cases of typhoid in which hemorrhage from the bowels occurred, it was preceded for a few days by slight hemorrhages from the mucous membrane of the mouth and gums. He gives the history of a well-marked case of typhoid in a boy of ten, admitted to the hospital, December 29th, with the history that he had been seriously sick for five days. The temperature ranged between 104° and 106° F., the pulse from 120 to 132; there was delirium at night, slight bleeding from the lips and gums appearing on the 30th. The cold water treatment was not used, because a little girl, on whom it had been used under like circumstances a few days before, had died of hemorrhage from the bowels. On January 2d, however, delirium increasing, he was put in a wet pack. The next day there was sensitiveness in the region of the spleen, and the bleeding from the mouth continued in spite of various modes of treatment. On January 5th the stools contained blood, and he fell into a state of collapse and died, the temperature falling from 104° to 97.2°, F., during the last six hours. At the autopsy, an ulcer, with hemorrhagic appearance of base and edges, and half an inch wide, was found on the posterior wall of the pharynx, between the orifices of the Eustachian tubes. The stomach and intestines contained altered blood; the Peyerian patches were the seat of the characteristic lesions of the disease, and the peritoneal cavity contained about a pound and a half of dark fluid blood. The source of this was found in the spleen, which organ was enlarged to four times its natural size and was the seat of two long and deep lacerations or ruptures, one of them two and a half inches long and an inch deep.—*Jahrb. f. Kinderheilk.*, *IX.*, 3, 1876.

Congenital Syphilis Treated with Iodide of Iron.—Dr. Alois Monti, of Vienna, claims advantages for the treatment of congenital syphilis with the *ferrum iodatum saccharatum* (Ph. Germ.) over the ordinary treatment with mercurials. He gives it dissolved in the milk, regulating the dose according to the age of the child. Thus, three grains are divided into ten doses, of which a new-born child will receive two or three in a day, while at one year of age three grains will be given in a day, etc. It should be continued as long as any manifestations of the disease remain on the skin or mucous membranes, or there is any anæmia or enlargement of the spleen. He claims that iodism is never produced under this treatment, and that, after a few days' use of it, the child becomes more quiet, and the symptoms of the disease begin to disappear. The duration of treatment is undoubtedly somewhat longer than under mercurials, but the nutrition of the child is not impaired; on the contrary, rather improved. Of course, it cannot be substituted for mercury in the treatment of cases requiring very prompt remedies, such as specific laryngitis, accompanied by stricture of the larynx.—*Jahrb. f. Kinderheilk.*, *X.* 3, 1876.

Anti-Vivisectionists.—Despite the report of the Royal Commission, the anti-vivisectionists of England are still active in their efforts to procure the passage of a bill to suit their ends.

Borax as an Antiseptic.—The antiseptic properties of borate of soda are being discussed in France, in connection with a proposition to preserve meats and milk by its agency.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

PUBLISHED BY

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, April 15, 1876.

MEDICAL SOCIETIES AND MEDICAL REFORMS.

THE discussion of the subject of medical education during the past few years, has not been altogether barren of results. The profession has not only maintained its right to criticise the doings of the medical schools, but has succeeded in commanding a respect for its opinion. So far as ultimate reform is concerned, this beginning is encouraging. But that the time is approaching when more radical measures must be initiated, seems quite evident if we rightly interpret professional feeling upon the subject. The medical journals throughout the country have fought against the abuses in our system of medical education almost single handed, and while the majority of the reading profession endorsed the views which have been expressed, and acknowledged the necessity for change, nothing more than professional opinion has been created.

Now, however, it seems that the societies are beginning to take hold of the matter and directly use the weight of their influence and authority in preventing that greatest of all curses to medical progress in this country—the multiplication of medical schools. Every one knows how easy it is to found a medical college, create professorships, advertise the professors, and graduate students. Nothing is easier, and nothing more profitable in one way or another, to those interested in the success of the school. The obtaining a charter is a matter of form, as is also the professorial appointments, and then we have another full-fledged and portentously named college added to the already lengthy list. The ease with which these institutions can be established has been a fact so much deplored by the profession at large, that any effort calculated to remedy the evil should be duly considered and appreciated. The Allen County Medical Society, of Indiana, certainly deserves consideration in connection with its recent action regarding the prospective establishment of a medical school at Fort Wayne. The resolutions bearing upon the question are of such length, that we cannot find room for more than a few extracts; but we trust that they will be sufficient to explain the principle and spirit of the action:

Dr. G. T. Brusbach, after pointing out the acknowledged evils attendent upon a multiplication of medical schools, concluded as follows:

Whereas, Reform in this matter, in order to prove successful, must commence with the County Medical Societies; and, as it is high time that some one should lead off in the premises, and endeavor to change these things; now, therefore,

Resolved, That the Allen County Medical Society learns with deep regret of the attempt to establish another low-grade medical school in this city, and hereby enters its earnest protest against the institution of any more so-called medical colleges in the State of Indiana.

Resolved, That the Allen County Medical Society hereby desires to be distinctly and explicitly understood as withholding any and all professional recognition from the hybrid concern, which, it is generally believed, is about to be established in this city, and from its aiders and abettors.

Resolved, That the Secretary be hereby instructed to make inquiry to that effect, and report if any members of this society are in any way concerned in the establishment of the school referred to, and to furnish a list of the names of such members to this society at its next regular meeting.

Resolved, That this society recognizes the establishment of the above school simply as a means of dishonorable advertising.

Following these resolutions were some offered by Dr. Joseph R. Beck, of equal purport, but if possible more radical in their aims. Both sets of resolutions were deliberately discussed and unanimously adopted.

The principle involved is eminently correct, and we await the result of the protest with some little concern. If the success of the measure can be established as a precedent, there will indeed be great reason for the encouragement of other societies who may be inclined to follow the example.

In connection with this subject we would also refer to another instance of determination on the part of a medical society to express an opinion in regard to the continuance of another medical school. The Iowa State Medical Society has protested against the endowment of a medical department to the present State University, on the ground that under the proposed management it could never be more than a second rate school. This protest was based mainly upon the fact that clinical and didactic medicine could not be efficiently taught in a small inland town.

We believe that this is one way of correcting a growing evil, and we hope that the time is not far distant when other medical organizations shall be equally explicit in their denunciation of wrong, and equally determined in their efforts at reform.

MEDICAL ADVERTISING.

The review of medical works by the secular papers is another one of the phases of medical advertising to which a passing reference should be made. At first sight it might appear as the merest accident that a newspaper should care to devote its review space to a strictly professional work; and that it was more the result of manœuvring by some enterprising publisher than any desire on the part of the author for public notoriety. When, however, the matter is examined in all its bearings, and the usual circumstances which hang upon ordinary chances are carefully weighed, there is but one way to settle the question why some medical authors are always fortunate, and others never have a chance. Of what use is it to the general public to know, through a newspaper, that Dr. A. has written a masterly work on diphtheria, an exhaustive treatise on scarlet fever, an elaborate book upon fractures, or joint diseases, or piles, except to prove that the author is an authority on the subject, and has more than ordinary qualifications for the practice of his specialty? And what is this more than medical advertising?

This practice has been carried on so extensively in Great Britain, that the profession there are beginning to appreciate its damaging effects upon their dignity, and are clamoring, through their journals, for reform. Not only do some authors allow their works to be noticed in the manner indicated, but favor the insertion of standing advertisements in the leading secular papers. The *British Medical Journal*, which has been particularly active in exposing such dishonest proceedings, has been directly instrumental in the passage of several resolutions by the branch societies of the British Medical Association. These resolutions condemn the practice in the most unmistakable terms. The journal in question speaks thus plainly in regard to this business of special advertising:

"It is more than doubtful whether the profit to the publisher from advertising a medical treatise in newspapers repays the cost. Such books are not commonly so advertised with a view to sell copies of them to the public, but to make known their titles and the names of the authors. In a large number of cases, it is notorious that authors devote an annual sum for the mere purpose of defraying the expenses of such advertising, and subsidize their publishers for the purpose. Medical publishers act, too, very largely as the agents for authors of the books which they publish; and if the leading medical publishers were asked, they would probably say that only a small proportion of the books on their list belong to them, and that they are those which are least advertised in the daily papers."

Although very little of this kind of advertising is done in this country, there is enough of it to draw the attention of those who are interested in maintaining the honor and dignity of the profession, and in keeping it above the suspicion of underhanded practices.

Reviews and Notices of Books.

A Manual of General Pathology, for the use of Students and Practitioners of Medicine, by Ernst Wagner, M.D., Prof. of General Pathology and Pathological Anatomy in the University of Leipzig, &c. Translated from the sixth German Edition, by John Van Duyn, A.M., M.D., Prof. Anat, &c., in Medical School of Syracuse Univ., N. Y., and E. C. Seguin, M.D., Clin. Prof. of Diseases of Mind and Nervous System, College of Physicians and Surgeons, N. Y. New York: William Wood & Co., 1876. 8vo, pp. 728.

The advances which have been made in the study of pathology invest this branch with a peculiar interest to the progressive student in medicine. The home for the science at present is Germany, for there, within the past ten years more particularly, the most thorough investigations have been carried on, and the greatest progress made in the elucidation of the laws of disease, and in the interpretation of pathological lesions. The work before us is a contribution to the literature of this school, and may be said to represent the advanced views now held by the progressive investigators, and the most careful workers in this interesting and important department of our science. Originally appearing as a small volume in 1862, it was the conjoint production of Profs. Uhl and Wagner, but by the death of the former, just previous to the issue of the work, its preparation for the press devolved upon the present author, who subsequently elaborated it, in successive editions, until it has reached, in its last issue, the portentous size of an elaborate and comprehensive text-book of over 700 pages.

It would be impossible to follow the author step by step through the volume, and present his views on the different subjects of which he treats, as such a plan would involve the writing of a small treatise in itself. His aim having been to condense as much as possible, he has so successfully carried out his plan that an immense variety of subjects are crowded into a comparatively small space, with only such elaboration as would enable the reader to understand the principles enunciated, and appreciate the significance of a fact. Indeed, he has in some instances sacrificed clearness to his desire for condensation. Although it may be impossible to go through the work in detail, an idea of its merit as a text-book for the student, and as a guide to the general practitioner, can be obtained by some statement in regard to the arrangement and subdivision of its component parts.

Before proceeding further, it is quite necessary to understand that general pathology, properly so called, embraces a very wide range of study, and comprises a thorough knowledge of everything pertaining to the morbid state, and to disease in general, whether it be in its nosological, etiological, pathological, physiological, or chemico-pathological relations. It may, in a word, be considered as the fundamental science of medicine proper, by a knowledge of which we are enabled to examine into the causes, effects, and treatment of disease.

When such a multitude of subjects is to be considered as will guarantee a reasonable completeness to the whole, it becomes a matter of more than ordinary concern with the student as to the system which the author may follow, and the skill with which he may classify. In the latter respect, Prof. Wagner has been successful, and has fulfilled all the conditions necessary to make the work, not only a very complete one, but a very available and systematic one for reference.

The reader is carried from the beginning to the end by an easy and natural method, and is enabled to appreciate the significance of each new fact, and the application of each new principle as he proceeds. General nosology, for instance, is the first subject presented, comprising a discussion of the nature and extension of disease, general symptomatology and diagnosis, general prognosis, course and duration of disease, and its termination in cure or death. Next follows general etiology, comprising the usual predisposing and exciting causes of disease, internal and external; those pertaining to the individual and to outside influences; and their general pathology, anatomy, and physiology, in its relations to the local disturbances of the circulation, to inflammation, and to the general disturbances of nutrition, in the shape of atrophy, hypertrophy, and the abnormal metamorphosis of tissue. In the latter, we may say in passing, are considered the formation and structures of the different morbid growths which are classified under the head of tumors.

The pathology of the blood next follows, under which heading the anomalies in structure of blood corpuscles, their deterioration, positive and relative, and the different hematic conditions which are associated with the different affections known as blood diseases are presented. Any one who has not studied general pathology in the comprehensive manner of its treatment by the author, will be astonished at the amount of useful information contained in the work, and will be gratified in finding such a thorough *résumé* of the fundamental elements of medicine.

The editors have done their work well under the circumstances. The style of English is not Addisonian, it is true, and a great many Germanisms have crept into the text; but by comparing the translation with the original, we are willing to make every allowance. Prof. Wagner has a style which is peculiar. He deals in parenthetic and involved sentences, and sacrifices everything else, in the expression of an idea, to brevity. The only fault with the translators has been, that they have followed him too literally, and have destroyed much of the beauty and smoothness of a freer rendering.

THE MEDICAL JURISPRUDENCE OF INSANITY, by J. H. BALFOUR BROWNE, Esq., of the Middle Temple, and Midland Circuit, Barrister-at-Law, &c. (London, Eng.) Second Edition, with reference to the Scotch and American decisions. Phila.: Lindsay & Blakiston, 1876. 8vo, pp. 713.

WHEN this work first appeared, in 1871, it was welcomed by the medical and legal world as one of the most valuable contributions to the medical jurisprudence of insanity in our language.

Since that time it has maintained its reputation, and has been studied with satisfaction by every one interested in the medico-legal inquiries bearing upon diseased conditions of the mind. A second edition comes to us, with additions and alterations, which render the work even more valuable, easier of reference, and more comprehensive in detail. Written by a barrister, the foundation of the treatment of the subject rests upon the legal responsibilities of the different varieties of insanity; but in order that such responsibilities should be clearly appreciated, a very careful analysis of the cases from a strictly medical point is made. Intended for both attorney and physician, it supplies the wants of each, and is a bond of mutual support to a strictly scientific opinion. The style of composition is admirable in terseness, and classic in the interest which it evokes on the subject, while the vast number of illustrative and curious examples of disease gives it a value which is peculiar to itself.

A TREATISE ON SURGERY, ITS PRINCIPLES AND PRACTICE. By T. HOLMES, M.A., Cantab., Surgeon to St. George's Hospital. Philadelphia: Henry C. Lea, 1876.

THIS is a work which has been looked for on both sides of the Atlantic with much interest; and the prompt appearance of the Philadelphia reprint is an indication of the estimation in which the author is held. Mr. Holmes is a surgeon of large and varied experience, and one of the best known, and, perhaps, the most brilliant writer upon surgical subjects in England. In his preface to this work he speaks of it as "to some extent an introduction" to the System of Surgery edited by him; and while that may be true of it in the way that an outline sketch would be an introduction to the completed picture, the expression does not do justice to the work. Books upon surgery may be classified as encyclopædical, clinical, and manuals, or text-books, each of which has its distinct field; although, of course, much of the same material is to be found in all. This book belongs in the third group, and its use is distinctly limited by the very qualifications which fit it for its place. It is a book for students—and an admirable one—and for the busy general practitioner. It will give a student all the knowledge needed to pass a rigid examination, but it will not give him all the details he will want to know, when he finds himself face to face with an important surgical case; those he will have to get from other books, or by experience.

It may well be doubted if work of this kind might not better be left to other hands. Mr. Holmes says that no man without a "personal experience of the various exigencies of surgery" should attempt to write such a book; but his own work shows evidence of the insufficiency of this argument. The experience of no man, especially in these days of specialism, covers all the topics, and the writer is tempted to give undue prominence to those with which he is best acquainted, so that many bare spots must be left. A text-book is a compilation, and its preparation belongs to that class of work which falls naturally to the part of young men of limited experience and abundant leisure:—those who supply the innumerable journal and dictionary articles, and who have sufficient knowledge, training, and experience to be able to compile intelligently. Men like Mr. Holmes would find a better and more useful field in the one in which he has already done so much that is valuable. Their work should be original, encyclopædical in fulness, or clinical in character.

It is impossible, within the space at our disposal, to enter into a detailed criticism of this book. It is an ungracious act to seek only for the defects; and where there is so much to praise, it is impossible to specify. The book fairly justifies the high expectations that were formed of it. Its style is clear and forcible, even brilliant at times, and the conciseness needed to bring it within its present limits has not impaired its force

and distinctness. It is profusely illustrated, but then many of the illustrations are worthless. The author's praiseworthy attempt to give drawings of the specimens in the pathological museums, has failed utterly in many cases. This apparently is not due to carelessness in making the drawings or wood-cuts, but to the inherent difficulties of the subject. Few specimens even can be understood without being handled and studied; how impossible then it must be to make a drawing which will convey a just idea of one. This failure is doubly unfortunate, because the space occupied so unprofitably has been gained by very close pruning of the text in many places.

From the American point of view, there are two subjects which deserve criticism. Mr. Holmes has not done full justice to that treatment of fracture of the thigh which is identified with the name of Dr. Buck. He does not seem to be practically familiar with the method of treatment, or with the record of its results.

In this connection, we may say that he has preserved the traditional distinction between the provisional and the permanent callus, a distinction which is not justified by pathological anatomy; and that he still classifies fractures of the neck of the femur as intra- and extra-capsular, and devotes a page and a half to their diagnosis—a diagnosis which can never be more than probable, and which has no practical value as regards either prognosis or treatment.

The second point is the treatment of stricture. He makes no mention of the use of a tunnelled instrument over a guide, and recommends treatment by tying in catheters; and in his directions for tying in, he tells us to pass the strings through the rings on the end of the catheter; and then, lest there should be any mistake as to his meaning, he adds (p. 790) that "the difference between a silver and a soft catheter, as regards their suitability for tying in, is certainly not very great." Such treatment is absolutely condemned by American authorities, as well as by many English and French. The latter tie in soft catheters occasionally when the difficulties of catheterisation are very great, as in cases of enlarged prostate, but they always do it under protest; and in the treatment of stricture the representative surgeons never leave a bougie in place for more than 15 minutes. Our American authorities go still further, and claim (Van Buren and Keyes) that the simple entrance and immediate withdrawal of a metal sound procures the best results.

Urethral fever, so common and so redoubtable an accident, is mentioned only in a foot-note (p. 795) as a name given to "distressing rigors," accompanied by a rise of temperature and great malaise. There is something wrong in the perspective of a writer who gives half a page to an instance of death following the removal of a small wen, and does not mention the possibility that division of a stricture, or even catheterisation, may have a fatal result.

The chapters on diseases of the joints and of the bones, are admirable; that on minor and operative surgery contains much that is very useful; the article on Lister's antiseptic dressing is a judicious departure from the general economy of space; and although we have felt compelled to criticise some points, we cannot close the book without saying that it is the best and most complete surgical text-book in our language.

The publisher's part has been well done. The illustrations have been skilfully copied, the text is clear and distinct. It is to be regretted that the marginal index of the original has been suppressed in the reprint.

Transactions of the Twenty-fifth Anniversary Meeting of the Illinois State Medical Society for 1875. Chicago: Fergus Printing Co., 244–248 Illinois St.

The volume is bound in cloth, and reflects credit both upon the Society and the publishers. It is made up largely of reports upon different branches, such as surgery, practical medicine, etc., and while reading them we became not only interested but fully convinced that the Western as well as the Eastern doctors disagree. To some of these papers, however, the remark made by one of the thoughtful members of the Society can with fairness be applied, namely, that they are "bare recitals of points of progress which is so faithfully done in certain of our journals and year books, or accompanied with loose and practically valueless comments on the same, that they should not burden the pages of the Transactions." In the report upon "Shortening in Fractures," Prof. Sayre, of New York, has a sharp rejoinder to the doctrine which he advanced at the annual meeting of the American Medical Association, held in Detroit in 1874. We incline to the opinion that the rejoinder would be endorsed by the great mass of the profession were its circulation equally extensive. The author of the report believes that some shortening almost invariably occurs, without regard to the plan of treatment adopted, and upon this point we think he is sound.

Transactons of the American Otological Society. Eighth Annual Meeting, Newport, R. I., July 21st, 1875. Vol. 2, Part 1. 98 pp. 8vo. Boston: James Campbell.

The publishing committee are to be congratulated on the promptness with which their task has been fulfilled. With a little more attention to proof-reading a few errors would have been eliminated. Thus in the list of officers for the ensuing year the name of Dr. C. H. Bennett is printed in place of Dr. C. H. Burnett. Other mistakes occur on pages 58 and 60.

The report on the Progress of Otology for the past year is divided into two portions, Dr. C. J. Blake having prepared Part 1st, which includes the anatomy and physiology, and Dr. A. Mathewson Part 2d, including pathology and therapeutics. These gentlemen have been fairly successful in their efforts.

Among the interesting papers contributed is one by Dr. A. H. Buck, on the method of using medicated Eustachian bougies. Nitrate of silver solution, of the strength of 20–40 grs. to the ounce, is the remedy he generally applies in this manner. A fine whalebone or cat-gut bougie, with a bit of cotton twisted about one end, is dipped in the solution and passed through the catheter, and so on into the Eustachian tube. This method is a very safe one, for the skill requisite in the manipulation will necessarily confine its employment to the hands of the experienced otologist.

Dr. Clarence J. Blake communicates some very instructive investigations on the intra-tympanic pressure during phonation, observed in a patient with purulent inflammation of the middle ear.

Two Thousand Years After; or, A Talk in a Cemetery. By John Darby. Claxton, Remsen & Haffelfinger, Phila. 1876. Pp. 103.

The plan of this little book is to have Socrates and his friends resume the discussion recorded in the Phædo two thousand years ago. The subject of discussion now is found in the positivist and materialistic doctrines, the errors of which the author tries to show with simple language and illustrations. The form of dia

logue which has been preserved is well adapted to a subject in treating which frequent explanations are necessary.

Reports of Societies.

NEW YORK MEDICAL JOURNAL ASSOCIATION.

Stated Meeting, April 7th, 1876.

DR. D. B. ST. JOHN ROOSA, VICE-PRESIDENT, IN THE CHAIR.

REPORT ON GYNÆCOLOGY.

DR. P. F. MUNDÉ read the annual report, in which attention was directed to the following subjects:

THE PHYSIOLOGY OF OVULATION AND MENSTRUATION.

Considerable space was devoted to the consideration of this question, and a large number of authorities quoted in support of the theories advanced respecting the relationship between these two functions. There were those who held that ovulation and menstruation were independent functions, and that the proof of such relation existed in the facts mainly that conception has occurred in non-menstruating women; that menstruation has taken place after the removal of both ovaries; and that evidence of ruptured Graafian follicle was not always found subsequent to menstruation.

Dr. Mundé, however, did not accept this doctrine, and placed himself with those who believed that menstruation is an accompaniment of ovulation, according to the old theory.

With reference to the changes which take place in the uterine mucous membrane at the time of menstruation, extensive reference was made to the writings of Williams and Engelmann. Williams holds that there is monthly shedding of the uterine mucosa, and that this takes place by way of a molecular disintegration of the mucous membrane of the uterus, which is followed by a hemorrhage; Engelmann believes that during the menstrual period, the uterine mucous membrane becomes swollen, but that the tumefaction is limited to the superficial layers, and with it is associated an enlargement of the blood-vessels, and consequent engorgement with blood. After a certain degree of tumefaction has occurred the superficial layer of the membrane undergoes a moderate degree of fatty degeneration, and gives rise to hemorrhage. After the cessation of the hemorrhage, the tumefaction gradually subsides and disappears.

Dr. Munde inclined to the support of Engelmann, and did not believe that the monthly shedding of uterine mucosa was a desquamation.

Referring to the

CAUSES OF MENSTRUATION,

the theory was mentioned that its cause is neither in the ovaries, the uterus, or the blood, but that it is probably in the ganglionic nervous system, and that the reason why it declared itself through the circulation was because the circulation was under control of that system.

INTRA-UTERINE APPLICATIONS.

The practical suggestion was mentioned in connection with this topic, that they should be used after, rather than just before, the occurrence of menstruation.

EARLY ABORTIONS.

Here reference was made to the theory advanced, that many cases of dysmenorrhœa in otherwise healthy sterile women were cases of repeated conception and abortion that passed unsuspected by either patient or physician. In such case the most common time for the occurrence of abortion would be at the end of four weeks instead of three months. If true, it established the importance of both macroscopic and microscopic examination in every case of dysmenorrhœa to determine the presence or absence of the decidua of conception. The treatment suggested was, quiet in bed, counter-irritation to the inner surface of the thighs, and opium preceding the time of anticipated menstruation.

EXPLORATIVE PUNCTURE OF OVARIAN CYSTS.

The doctrine taught was, that such explorative punctures, with the hypodermic needle, or the needle of an aspirator, should not be resorted to unless indispensably necessary to a diagnosis. The danger was subsequent peritonitis. Dr. Peaslee was referred to as authority for the statement that the needle of the aspirator should not be regarded as any safer than a trocar and canula, and that recourse should not be had to either unless everything was ready for the performance of the radical operation within twenty-four hours. Under the head of

OVARIAN THERAPEUTICS,

it was said that the idea had been advanced that ovariotomy might become obsolete, for the reason that a radical cure of ovarian cysts by means of electrolysis had been reported. Whether that method of treatment would stand the test of time, remained to be seen.

POSTURE OF THE BODY AS A CAUSE AND A CURE FOR UTERINE DISEASE.

It has been held that the erect, the sitting, the kneeling, the reclining, and the recumbent positions are all proper if properly employed, and not persisted in too long. For example, the erect position should be maintained only for a short time, unless the body was kept in motion; sitting in a chair so high that the feet cannot find firm support upon the floor, was improper; the recumbent posture should be upon a level plane, either soft or hard, etc., etc. The posture treatment in overcoming displacements of the uterus has been advocated, and instruments devised for facilitating the entrance of air into the vagina to assist—for example, in reproducing a retroverted uterus; the woman, meantime, favoring its return by placing herself in the knee-breast position.

TREATMENT OF UTERINE FIBROIDS.

Meadows has claimed that these tumors can be influenced by the administration of the chloride of calcium and ergot; but that any benefit may attend their use, both remedies must be given perseveringly for months.

Byford has answered the question in the affirmative, concerning the cure of uterine fibroids by the use of ergot.

GASTRO-HYSTEROTOMY.

Within the last year nine cases of this operation have been performed, and of these six recovered. Billroth, after several unsuccessful operations, has finally come to recommend it as justifiable, having succeeded in one of his own cases.

BILATERAL DIVISION OF THE CERVIX UTERI IN DYSMENORRHŒA.

Bilateral division of the cervix has been performed for the relief of dysmenorrhœa depending upon conoidal cervix, flexion, and constriction of the external os; but the results have been so unsatisfactory, that it has become questionable whether the operation should be continued.

INTERMITTENT APPEARANCE OF A FIBROUS POLYPUS.

A case had been reported where a polypus appeared at times in the os uteri, and then retreated altogether beyond sight. The explanation was, that at the menstrual epoch hyperæmia took place, the tumor increased in size, pains followed, and as a result of such uterine pains the polypus made its appearance. One condition was regarded as necessary to the development of the phenomenon, and that was sufficient vascularity of the tumor. With regard to operating for the removal of such polypi, it was thought better to operate during menstruation, because less dangerous, than to wait until the hyperæmia had passed away and the mouth of the uterine had become closed, thus requiring the use of the sponge-tent, etc., to gain admission to the uterine cavity so as to reach the polypus.

LOCAL APPLICATION OF STRONG NITRIC ACID IN THE TREATMENT OF UTERINE DISEASES.

Dr. Mundé was of the opinion that the local use of strong nitric acid in the treatment of such diseases as endometritis, menorrhagia, endo-cervicitis, etc., had not met with the encouragement which it deserved. He recommended its thorough application to the internal surface of the uterus, after dilatation of the cervix—for example, in a case of obstinate follicular degeneration of the uterine mucous membrane.

TREATMENT OF GONORRHŒA IN THE FEMALE.

Dr. Palmer had recommended that the patient be placed in the knee-elbow position, air be allowed to distend the vaginal canal, the vagina be thoroughly cleansed, and after the water has been allowed to escape, refilled with a solution of sulphate of zinc of the strength of a table-spoonful to the half-pint of water. Repeated daily, and a complete cure might be expected within a week or ten days.

Attention was called to the fact that vaginal syringes should never have a central opening, for, with a hole in the centre of the tube, there was liability of exciting unpleasant, and, it may be, serious symptoms, especially in cases of wide cervix, ruptured cervix, or a cervix left open by operation, because of the injection of water into the uterine cavity. For that reason the fountain syringe was prefered.

PECULIAR PSYCHICAL CONDITION DEVELOPED BY ETHER AND CHLOROFORM.

Females were said to be specially liable to experience the sensation of sexual congress, or that their persons were being violated, when passing under the influence of ether and chloroform; hence, the precaution should be taken, never to attempt to bring them under the influence of these anæsthetics without having a third person present.

CYSTITIS IN THE FEMALE CURED BY DILATATION OF THE NECK OF THE BLADDER.

Dr. Howe had reported several cures of cystitis in the female, effected by manual dilatation of the urethra. Dr. Noeggerath had reported his success in exploring the pelvic organs through a dilated female urethra. Simon had laid down the rule that the female urethra might be dilated to eight-tenths of an inch in diameter without injury; and had also performed catheterization of the ureters in connection with such dilatation.

Dr. Munde's report was listened to with attention, and, being open for discussion.

Dr. J. C. Peters mentioned a case of uterine polypus which appeared at stated intervals, and then retreated, and was treated by a homœopathic physician with high dilutions, on the supposition that the woman had been relieved of a large number of these polypi, as the direct effect of taking the medicine.

The polypus was subsequently removed by Dr. Peaslee.

Dr. A. A. Smith reported a case in which dilatation of the urethra was effected in a girl 8 years of age, sufficient to readily admit his index finger, probably three-fourths of an inch in diameter. Palmer's instrument was employed. The dilatation was for the removal of a calculus, and the girl made a good recovery.

Correspondence.

DAWSON'S *versus* PIFFARD'S GALVANO-CAUSTIC BATTERY.

To the Editor of The Medical Record.

My Dear Doctor:—Will you allow me to correct some errors in the report of the meeting of the Medical Journal Association of March 10th, in The Record of the 25th March, page 201: at which meeting Dr. Piffard read a paper entitled "The Proper Construction of Galvano-Cautery Apparatus"?

The report says, in third paragraph from the top of page 202, "Dawson's battery has two negatives, *i. e.* one platinum plate and four zincs, to each cell. . . . . The platinum plates in Dr. Dawson's battery were somewhat larger than those of Dr. Piffard's." The sized battery which I have offered to the profession has but one negative, and two zincs, or positive plates, to each cell; for I found by experimenting, that plates of a certain size, and of such a combination, were of sufficient power for all practical purposes. As to my platinum plates being larger than Dr. Piffard's, *they are not*, and, I believe if accurately measured, would be found to contain less platinum by weight. Dr. Piffard used platinum plates $6\frac{1}{2} \times 4\frac{1}{2}$, while I use platinum $5\frac{1}{2} \times 4\frac{1}{4}$. Again, in the succeeding paragraph, the report says: "The quantity of fluid required by Dr. Piffard's battery was somewhat less than that required by Dr. Dawson's." This also is an error, for both Dr. Piffard and myself stated that each battery held a little less than a quart of fluid. In paragraphs ten and eleven your report also says that I exhibited a battery which "Dr. Piffard allowed was more powerful than the one he had devised, but was not the apparatus I had placed upon the market," and that I "admitted it was not the instrument upon the market bearing my name." The battery referred to was in every respect one of my batteries, and as much entitled to bear my name as will any other. It was simply more powerful than the one Dr. Piffard calls my "commercial" battery, from its having an additional negative and positive plate to each cell, which addition was made expressly to show Dr. Piffard that if I used the same number of plates to each cell that

he found necessary in the one he exhibited, *in conjunction with the other special advantages I claim* for my battery, I obtained a battery which he acknowledged was more powerful than his. *The number of plates* in each cell of my battery, if the measured size of the apparatus is not thereby increased, has nothing to do with the special characteristics of construction I claim as original. Dr. Piffard certainly will not admit that the addition of extra plates to a given sized battery entitles it to a new name. By uniting two similar batteries (as, for instance, two of my own), one will get double the amount of power, but cannot claim the possession of a *new kind of battery*.'

Very truly yours,

B. F. Dawson, M.D.

TREATMENT OF FRACTURE OF CLAVICLE.

To the Editor of The Medical Record.

Dear Sir:—The article on the treatment of fractured clavicle, by Dr. F. Staples, in No. 282 of The Medical Record, causes me to ask the insertion of the following note, which I added to the chapter on Fractures of Clavicle, in my German translation of Dr. F. H. Hamilton's book on Fractures and Dislocations:

"The late Dr. E. Krackowizer devised an apparatus for the purpose of holding the shoulders back in this fracture, which he intended using whenever he should attend a case of fractured clavicle, where the patient should think it of importance to avoid all deformity. A metallic padded belt is fastened around the waist; from its anterior middle arises a metallic rod, running upwards along the sternum, at a little distance from the thoracic walls, until, on a line with the shoulder-joints, it divides into two lateral branches, which extend to the axilla on either side, where they again terminate in two vertical branches, so curved as to grasp the shoulders, and push them back by the turning of a screw. The patient must lie on the back during the entire course of treatment. Dr. Krackowizer preferred this contrivance to Heister's cross, as, in his opinion, it required less pressure upon the shoulders than in either Heister's or any other kind of back splint." Respectfully,

A. Rose, M.D.

265 Seventh Street.

TWO COURSES IN THE SAME YEAR.

AN ANSWER FROM THE ATLANTA MEDICAL COLLEGE.

To the Editor of The Medical Record.

Dear Sir:—In your editorial of April 1st, you quote from the *American Medical Weekly*, of Louisville, to the effect, that the Atlanta Medical College gives, or has given, two courses of lectures in the same year. Dr. Gaillard, of the *Weekly*, seems to have made the statement in justification of his own school. The statement needs correction.

The lectures of the Atlanta Medical College, from its organization till the past five years, were given in the summer—there being then no winter session. The exercises were suspended during the war. It was found impossible to resume in the summer immediately following the close of the war, the college building having been used as a hospital by both armies, and entirely despoiled of its equipments. Hence, the session of that year was necessarily postponed till winter. The next summer the regular schedule was resumed. This is the only ground on which Dr. Gaillard can possibly base his statement. You will perceive the injustice of it.

I would further state, that in 1871, the course was permanently changed from summer to winter. There was no course from the summer of that year to the winter of 1872 and 1873. Observe the interval of eighteen (18) months. One winter was omitted, that we might *avoid* the holding of two graduating courses in one year.

Please do us the justice of correction, by publishing this note.

Very respectfully,

J. T. Johnson, M.D., *Dean.*

Atlanta *April* 7, 1876.

BLEPHARO-ADENITIS WITH FISTULÆ.

To the Editor of The Medical Record.

Sir:—I attempt to describe the above disease, in connection with two cases which I have seen lately in Dr. Agnew's clinic, at the Manhattan Eye and Ear Hospital. I have seen no work on diseases of the eye in which this trouble is mentioned.

L. B., age 21, has had lid trouble for six months; has had no treatment beyond household remedies. On everting upper lids, bodies appearing at first glance to be trachomatous are visible. Looking more closely, the centres of these bodies are found to be depressed. These depressions are surrounded by rosettes of minute granulations. Taking a small probe and inserting it into an umbilicated centre, it was found to lead into a sinus connected with a Meibomian follicle. Some of these openings were as far back as the superior edge of the tarsal cartilage, each upper lid having (6) six or (7) seven on it.

One week later, E. L., age 30, presents herself with the same trouble. Both patients had chalazion of both upper lids. They no doubt had had a series of chalazion, that had opened themselves on the surface of the palpebral conjunctiva, these openings resulting in fistulæ.

The treatment to be pursued here is the same as that for fistula in other parts of the body, either by slitting up or cauterization. These were healed by applications of nitric acid to as much of fistulæ as could be reached. First patient, after two applications, returns greatly improved.

W. Cheatham, M.D.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department United States Army, from April 2nd to April 8th, 1876.

McCormick, Chas., Surgeon.—To proceed to New York City, and, on arrival, report by letter to the Surgeon-General. S. O. 65, A. G. O., March 31, 1876.

Bentley, E., Assistant Surgeon.—Assigned to duty at Camp Independence, Cal. S. O. 25, Department of California, March 18, 1876.

Fitzgerald, J. A., Assistant Surgeon.—When relieved by Assistant Surgeon Ainsworth, to report in person at these Headquarters for assignment to duty. S. O. 31, Department of the Columbia, March 24, 1876.

Ainsworth, F. C., Assistant Surgeon.—Assigned to duty as Post-Surgeon at Sitka, Alaska. S. O. 31, C. S. Department of the Columbia.

Comegys, E. T., Assistant Surgeon.—Assigned to duty at Plattsburg Barracks, N. Y. S. O. 58, Military Division of the Atlantic, April 4, 1876.

Medical Items and News.

Contagious Diseases.—Comparative statement of cases of Contagious Disease reported to the Sanitary Bureau, Health Department, for the two weeks ending April 8th, 1876. Walter De F. Day,
Sanitary Superintendent.

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-Spinal Meningitis.	Measles.	Diphtheria.	Small-pox.
April 1st.....	0	4	76	5	65	71	26
April 8th.....	0	7	91	4	59	100	40

Success in Practice.—Dr. Wm. B Davis, of Cincinnati, in an address delivered to the graduating class of the Miami Medical College, gives some of the statistics of the medical profession of Cincinnati, by which it is shown that of all who entered the profession during the past 25 years, three-fourths failed. It is also shown that, of the physicians of Cincinnati who were "*resident physicians*" of the Cincinnati Hospital, all succeeded.

University of Pennsylvania, Medical Department.—The Medical Department of the University of Pennsylvania has for a long time entertained the idea of lengthening the period of medical study and grading the course accordingly. As a commencement in this direction, the trustees have elected four gentlemen from the staff of the University Hospital as members of the Faculty, creating the four extra chairs to which these gentlemen are to be attached. The appointments are as follows: Morbid Anatomy and Pathology, James Tyson, M.D.; Clinical Surgery, John Neill, M.D.; Clinical Medicine, William Pepper, M.D.; and Diseases of Women and Children, William Godell, M.D. The other members of the hospital staff—Drs. Wood, Norris, Strawbridge, and Duhring—retain simply their former positions, being specialists. The newly-elected professors will receive no emolument until an endowment fund is raised, and the position and titular honors of the other professors are to remain unchanged.

Professor of Hygiene at Netley.—The professorship of Hygiene at the Army Medical School at Netley, now vacant by the death of Prof. Parkes, is worth £1,000 per annum.

The British Army Medical Staff Bill, now known as the short service scheme, is not likely to become a law. There is the strongest kind of opposition to it by the medical press and the profession generally.

Scarlet Fever.—Several schools in England have been closed in consequence of the prevalence of scarlet fever.

Medical Advertising.—The subject of medical advertising is attracting the attention of our British cousins. On the whole they take very strenuous grounds. Not only do they object to the advertising of medical colleges in the daily papers, but to the announcement of medical works and their review in the secular prints.

Medical Centennial.—Among other distinguished men to visit America at the time of the Centennial, will be Prof. Lebert, University of Breslau; Prof. Jaccoud, of Paris, and Stromeyer, of Hanover.

Bellevue Hospital Medical College.—At a recent meeting of the Faculty of Bellevue Hospital Medical College, Dr. A. A. Smith was elected Lecturer Adjunct to the Chair of Clinical Medicine, and Dr. L. M. Yale, Lecturer Adjunct to the Chair of Orthopædic Surgery.

School Children and Dangerous Communicable Diseases.—Dr. Arthur H. Nichols, in a recent number of the *Boston Medical Journal* (Mar. 23), contributes a very sensible article upon the above subject, from which we extract the following recommendations:

"Considering, however, that it is the imperative duty of the school authorities to adopt the most stringent measures designed to interpose a check to the unlimited spread of these diseases, I would venture to suggest some such rules as the following, as best calculated to meet the end proposed: –

I. No pupil shall be allowed to attend school from any house in which small-pox, varioloid, or scarlet fever is prevalent.

II. A pupil who has been affected with small-pox, varioloid, measles, or scarlet fever, shall not be permitted to return to school until, desquamation having ceased and convalescence being complete, the surface of the body shall have been finally disinfected by means of warm baths (with abundant soap), applied upon four successive days, or until no trace of roughness of the skin remains. The pupil, furthermore, shall not be allowed to reënter school until the teacher shall have received satisfactory evidence that all clothing worn by the patient has been thoroughly disinfected, and that the sick-room and its contents have been properly cleansed. If the teacher is not satisfied that all practicable disinfection has been effected in the case of any pupil, said pupil shall not be re admitted until three weeks shall have elapsed from the beginning of convalescence.

III. No pupil shall be allowed to attend school who is affected with diphtheria or whooping-cough.

Both parents and instructors should be informed as to the measures requisite for the disinfection of the clothing, sick-chamber, etc.* They should also be made to appreciate that a neglect of these precautions, when children are allowed to return to school after slight cases, forms often a principal source of epidemic infection.

It is hardly necessary to add that, under the supervision of a qualified medical inspector, to whom all obscure or doubtful points might be referred, a much more intelligent and judicious enforcement of these rules might be expected."

HINTS TO PRACTISING PHYSICIANS REGARDING CORONERS' INQUESTS.

BEING A PAPER READ BEFORE THE YORKVILLE MEDICAL ASSOCIATION, N. Y., MARCH 14, 1876.

By WOOSTER BEACH, M.D.,

NEW YORK.

The duties of coroner in this city are not very clearly defined by statute; and, even with the aid of legal precedents and of common law, his prerogatives cannot very definitely be determined. The officer in England has unusual powers, and is directly responsible to the king. His intimate relation with the crown suggests his title. "Crowner's quest law" has been a favorite topic with writers, both old and new, but they usually treat it in a style not particularly grateful to the feelings of the important functionary administering the law. Even the immortal bard, in several of his plays, has taken numerous liberties with the dignity of the office. So perhaps the coroner of to-day may comfort himself with the reflection that the strictures of his numerous critics are rather the result of an old, time-honored custom than of any just cause of complaint against him.

The statutes of 1871, relating to the coroners of the city and county of New York, is about the only law of interest to our practising physicians bearing upon this subject. Section one of that law provides that "Hereafter, when in the city and county of New York any person shall die from criminal violence, or by a casualty, or suddenly, when in apparent health, or when unattended by a physician, or in prison, or in any suspicious or unusual manner, the coroner shall subpœna a properly qualified physician, who shall view the body of such deceased person externally, or make an autopsy thereon, as may be required. The testimony of such physician and that of any other witnesses that the coroner may find necessary, shall constitute an inquest. For making such external examination the physician shall receive three dollars, for making such autopsy he shall receive ten dollars, and such sums shall be a county charge and be paid by the Board of Supervisors.

Section I. provides that the coroner may dispense with a jury in certain cases.

Section III. says: "It shall be the duty of any citizen who may become aware of the death of a person who shall have died in the manner stated in Section I. of this act, to report such death forthwith to one of the coroners, or to any police officer; and such police officer shall, without delay, notify the coroner of such death; and any person who shall wilfully neglect or refuse to report such death to the coroner shall upon conviction be adjudged guilty of misdemeanor, and shall be punished by imprisonment in the county prison not exceeding one year, or by a fine not exceeding five hundred dollars, or by both such fine and imprisonment."

Section IV. provides that "Any person except the coroner who shall wilfully touch, remove, or disturb the body of any one who shall have died in the manner described in Section I. of this act, or shall wilfully touch, remove, or disturb the clothing or any article upon or near such body, shall upon conviction be adjudged guilty of misdemeanor," &c.

The coroner has the power in holding inquests to summon and compel the attendance of medical as well as other witnesses. The physician is obliged to give his testimony at the inquest, as in other courts of justice. The coroner has no means of enforcing an order for a post-mortem examination, and before the law of 1871 he could not even promise payment for such service. The practice in this city is for each coroner—there being four—to choose a physician who accompanies him on his rounds, and makes all the external and post-mortem examinations as required by the above law, and also attends to the clerical duties of the inquest, an arrangement which, under the present system of choosing the coroners, is as good as any other. This physician is usually known as *deputy coroner*, but the law recognizes no such office. In fact, it expressly states that the coroner shall delegate none of his powers to another.

The physician in this city, therefore, that has charge of a patient who may become the subject of an inquest, does not usually make the post-mortem examination connected therewith. Should he desire to do so, it has been the custom to extend that privilege to him; or should he prefer, he may simply be present and witness it. Physicians in very many instances do not avail themselves of this privilege. The reason may be in some cases, that they are not aware of their right to be present, or in others that they absent themselves from fear of being called as a witness in the case; or perhaps they will not subject themselves to the inconvenience of attending the inquest. In any case, it seems to me, that in their failure to be present, they omit an important duty both to themselves and to the cause of justice. It is true that, for the latter reason, the coroner should endeavor to have the physician take part in the autopsy; but his omission to do so does not lessen the obligation of the latter to be present. The proper plan, when he has a coroner's case, would be, as soon as possible after the death of his patient, for him to visit the coroner's office, where he could make full arrangements for the post-mortem examination with the clerk, or with the doctor in whose hands the case might fall. His presence at the autopsy would not probably increase his liability to witness duty, either before the coroner or in the trial that follows; but if it did become necessary for him to testify, how much better he could acquit himself if he had the advantage of the knowledge obtained from the inspection of the dead body.

In all cases in which a patient may die from causes requiring judicial investigation, I would suggest that careful notes be taken, not only of the medical treatment, but of the surroundings, the persons present at the various visits, and of such other points as would recall the case perfectly to mind. Should the patient be wounded and the clothes still on, they should be carefully examined for cuts, bullet wounds, or other marks; and the entire surface of the body ought, if possible, to be looked over for bruises, scratches, discolorations or wounds, and their position and appearance noted. The necessity of observing apparently unimportant points is frequently shown on trials where a most creditable direct-examination of a medical witness has been made to appear entitled to doubt, from the cross-examination bringing out the fact that objects and circumstances noticed and testified to by others were not known to him; making it appear to the jury that if his observation of things in general was deficient, a like deficiency would probably be expected in matters relating to his patient.

Measurements of wounds, their direction, extent, and various peculiarities that may be expected to re-

main unchanged till after death, I do not propose to touch upon. Their proper consideration would consume far more time than could be given to a paper of this character. At present, I merely propose to direct attention to the duties required in a class of cases liable to fall to the lot of any practising physician, and my limits will scarcely more than allow an allusion to them. The study of post-mortem appearances, as treated upon in the works on medical jurisprudence, is an interesting one. Although it may be of no direct practical use to doctors in general, it will teach them a proper method of observation, when such observation may become necessary. Of American works on the subject, Beck's, though old, is good, but that of Wharton and Stillé is more modern and better adapted to the present time. Of the English authors probably the most comprehensive, although quite concise, is Taylor. Guy is also to be recommended.

Patients who may become ill soon after receiving kicks, blows, or other injuries, and die, are often the cause of trouble to the physician. The friends naturally ascribe death to the violence received; and it requires some tact on the doctor's part, in cases where he positively knows such illness to be independent of the injury, to convince the friends of their error. In all cases of this kind, where there is a chance that any disaffected person may revive and publish their suspicions at a future time, it would be proper to turn the case over to the coroner, or at any rate to insist on a post-mortem examination being made. Rather sudden deaths sometimes give rise to suspicion of poisoning among the attendants or friends of a patient. The same course should be pursued in this, as above suggested.

Should the doctor really feel that he had grounds for suspicion, he should observe the same precautions in regard to carefully taking notes as before spoken of. If vomiting occur in such cases, the matter ejected ought to be collected and preserved, if possible, in *new* vessels, sealed and put away where it could by no chance be disturbed. In any case where a physician is called as a witness, all his testimony will carry much greater weight if it is shown that he has used especial care in everything that he has done, even if what he did availed nothing directly in elucidating the case.

There is probably no class of cases that may engage the attention of a physician in this city that requires greater judgment and care on his part than those resulting from criminal abortion. I believe the fact to be well established, that not unfrequently women subject themselves to an operation by some professional abortionist, and when the resulting miscarriage follows, call in their family physician to attend them. I would not assert that the doctor *knows* the cause of the abortion in these cases, but are there not instances where no steps are taken by him to confirm his well-founded suspicion? Perhaps he rather avoids inquiries tending to make the matter too clear, and compel him to solicit a proper investigation. I would not insult my professional brethren by doubting that they would pursue such a course, when they had unmistakable proof that a crime of this character had been committed; but does the medical man do his duty when he omits the slightest opportunity to suppress this vile crime? But I find myself diverging from the proper scope of this paper—it is only cases of death or impending death from criminal abortion that should engage our attention. If a physician has good cause to believe that a woman on whom he is attending has been the subject of a criminal abortion, and is in danger of death, he is bound by law to notify the coroner of her condition, that her ante-mortem examination can be taken. Should she die, it is scarcely necessary to say that the case becomes the subject of a coroner's inquest. The extreme caution necessary to be exercised in treating females with whom the physician may be unacquainted is illustrated by the following case. The attention of the police, from some reason, was called to a young woman who had suffered a miscarriage; and as there seemed to be grounds for suspicion that it had been brought on by criminal means, she was questioned by the officer of the law in regard to it, when, in answer to his inquiries, she said that a short time previously she had called on Dr. ——, who had used an instrument on her. Upon this statement the doctor was arrested at once and imprisoned. Luckily for him he was almost immediately able to prove that the only instrument he had used was a speculum, and he was further able to show that he was unaware of the woman's condition. The gentleman, now deceased, had an unblemished reputation and was among the first in the profession.

The duty of the physician in regard to *ante-mortem* examinations is of importance, and should be more generally and thoroughly understood. An ante-mortem inquisition is imperatively required upon a person who has been injured by criminal violence and is in a dying condition, when his statement is the only or the principal evidence against his assailant.

Its object is twofold: first, for the purpose of procuring testimony that may be used on the trial succeeding the inquest; second, that the coroner may obtain jurisdiction in the case, and consequently the power of arresting suspected persons, or binding over witnesses to appear at a future time. No testimony taken by the coroner at an inquisition, either before or after a death, can be admitted on any subsequent trial. The deposition of witnesses, no matter of what importance, cannot be used as evidence, except on the inquest itself, for the guidance of the coroner's jury; nor can any statement made to a physician or others by the wounded person, no matter under what circumstances, be of any value except before the coroner. It is all classed as *hearsay testimony*, and is invariably excluded by the courts—with one exception. It is important that this exception should be clearly understood by the physician, as his knowledge of it may be the means of bringing offenders to justice, that might otherwise escape. It is the *dying declaration* of an individual, taken in a legal manner by a proper officer. To be valid and accomplish its object, the person by whom it is made must be in actual danger of death. He must himself fully entertain the belief that he is about to die.

In taking this deposition no oath or affirmation is administered to him by the coroner. The law attaches so much weight to a statement made under the solemn influence of the condition connected with impending dissolution, that it dispenses with the form always required at other times when testimony is taken. As a rule, the dying declaration is included and forms part of the ante-mortem examination, and may even constitute the whole substance of it; but the two are not necessarily connected. In the ante-mortem, a jury is called, who are also witnesses to the declaration; but the form of the latter is not important. Any writing that states clearly the condition of the wounded person, and sets forth the information that may be required from such person in an intelligent manner, relating, usually briefly, how his or her wounds or injuries were received—and signed by the coroner and two or three witnesses, is all that is required.

I explain this rather fully, as the law gives the

right to hold such examinations, as well as other inquests, to any justice of the peace or alderman, providing a coroner cannot be found, or is otherwise unable to hold it. The official called, perhaps for the first time, to act in place of the coroner, may be ignorant of the proper method of procedure; and should the physician be able to supply him with the lacking knowledge, particularly in a case where delay might defeat the purpose of the investigation, he would render invaluable service.

Private families usually have a great repugnance to an inquest being held on any of their members, or at their residences; and often endeavor to prevent it, even when it is required by law. While there may be some reason for this, the annoyance to them, by proper arrangement, may be extremely slight; and it will probably fall to the lot of the family physician to arrange matters in such a way that the minimum trouble shall be given by the proceedings. An inquest, in the majority of cases, is quite informal, and consists only of the deposition of two witnesses, with the medical testimony. This evidence is laid before a jury of six, who agree on a verdict, sign their names; and that, with the signature of the coroner, constitutes the entire proceeding. To prepare for the inquest, it is the work of a few minutes to select *nine* neighbors, within easy call, to be on hand when required, and the jury part is disposed of. The law requires nine to be summoned, but when six appear they can act. The witnesses may now be selected by the doctor, and advised to hold themselves in readiness for the coroner's visit. One should be a relative or intimate acquaintance of the deceased, and the other have a full knowledge of the particulars of his last illness and death. With these preliminaries cared for, a coroner's inquest will occasion only the slightest inconvenience. It would be much better for the doctor to take the trouble to carry out this plan in cases where he has doubts of the propriety of granting a certificate of death, than to give the certificate and run the risk of subjecting himself to the penalties that may result from his infringement of the law. Physicians are frequently called upon to give certificates after death, when they may not have attended the person dead. There is no law to prevent the doctor from giving it; but section one of the law of 1871, says that a person dying unattended by a physician shall be the subject of an inquest, and makes it necessary for any one cognizant of a death occurring in this way, to report it, without delay, to a coroner or to a police officer. It is well, in giving a certificate in a doubtful case, to write a full and clear statement of the facts connected with it, on the back of it, where space is provided for the purpose; or, still better, to call on the Department of Vital Statistics, connected with the Board of Health, where the disposition of the case can be determined. The registrar has always granted permits, in cases not definitely stated by law as falling to the jurisdiction of the coroner, when he has had it made clear to him that the ends of justice would not be defeated thereby.

A CASE OF POPLITEAL ANEURISM TREATED BY DIGITAL PRESSURE.

By R. W. HUTCHESON, M.D., M.R.C.S. Eng.

John Farrington, æt. 33, laborer, a native of Long Island, has always enjoyed good health, with the exception of an attack of ophthalmia, from which he suffered when a boy. Has always been temperate. Has been working in a grist mill during the last four years, where he has been engaged in lifting heavy weights, and supporting them on his knees. Noticed in July that his left knee was getting stiff, and on rubbing it discovered a small swelling in the popliteal space. He continued to follow his occupation, however, and the tumor slowly increased until January; when, having adopted a more vigorous plan of treatment, such as rubbing, poulticing, etc., it rapidly increased in size, and the leg became œdematous and painful, so that he was unable to walk.

The patient came under my care February 8th. He was then pale and nervous; bowels constipated; in fact, they had not been moved for ten days. Was taking freely of the elixir of opium to relieve his distress. Pulse 80, hard and intermittent; appetite poor; urine scanty and high-colored, with difficulty in passing it.

The left leg was somewhat flexed, stiff, painful and throbbing, with a bulging in the popliteal space, where a tumor about the size of a lemon was situated, tense to the touch; but, on compressing the femoral artery, the tumor ceased to beat and became soft, showing the absence of fibrinous deposits.

The patient was ordered a cathartic, and after its operation the tincture of iron was prescribed.

February 9th. Commenced digital pressure with lay assistants, which was continued for eight hours, but so imperfectly as to produce little or no results.

February 11th. Pressure with Signorini's tourniquet was applied to-day, and continued for three days; and, although well padded and frequently changed, it irritated the surface so much that it was discontinued.

February 15th. Firmly believing in the efficiency of digital pressure, I again resorted to that measure, but this time under more favorable circumstances. I obtained three or four volunteers, one of whom was a physician, and I stayed by the patient for fourteen hours myself. I soon discovered the secret of a speedy success, and that was to keep a steady pressure on the artery, without letting, if possible, a single wave of blood pass under the finger. I found, by experience, that it was quite impossible to accomplish that with the unaided hand. Sometimes the pressure would be too great; then again it would not be sufficient, and the blood would pass. And even with the thumb of another person pressing on one's own finger I found the same difficulties. At last I hit on a plan, which I have since ascertained was first recommended by Mr. Holden of London. I made a conical bag, and filling it with ten or twelve pounds of shot, I suspended it above the leg with the small end resting on the end of the compressing finger. This afforded efficient and steady pressure, which, although causing numbness of the finger, could be easily borne for an hour at a time.

In this way we kept up a continuous pressure for twenty-two hours, with the result of completely curing the aneurism in about sixteen hours; that is to say, the tumor became in that time hard, and ceased to beat; but the pressure was continued six hours longer to make the cure more certain. Indeed, when I left the patient at the end of the twenty-two hours, I intended the pressure to have been continued longer, and so directed; but to my surprise, when I returned a few hours after, I found everything removed.

It was curious to notice the changes in the force of the circulation in the artery when the pressure was first applied. Sometimes the artery would beat with renewed vigor, lashing the blood against the finger; and then again the current was so small as scarcely to be felt.

I applied the pressure in this instance in the middle

third of the thigh, not from choice but from necessity, as the skin over Scarpa's triangle was somewhat irritated from the pressure of the tourniquet which had been previously employed.

As regards the site of pressure, however, my attention was drawn to one circumstance which, I think, is worthy of notice, namely, that when the pressure was applied in the groin the foot became considerably colder than when applied lower down; as pressure below the origin of the profunda, therefore, causes the least interruption to the circulation of the blood in the leg, I very much question whether the upper third of the thigh is the most judicious site to apply the pressure in a popliteal aneurism. True, in the upper third the artery can be better isolated from the vein than lower down, where the vein passes behind it; nevertheless, I think that by applying the pressure as near the tumor as practicable, it gives the anastomosing arteries around the knee a better chance to accommodate themselves to the altered circulation than when it is applied high up, where, when the pressure is removed, the current of blood must necessarily be again considerably altered.

As to the amount of pain which the pressure occasioned the patient, I think it may be set down as slight, as he was able to doze during the night; but changing fingers appeared to have caused some distress. The patient subsequently complained of uneasiness around the knee-joint, which is said to arise from the stretching of the anastomosing arteries. An artery on the inner side of the knee, about an inch below the joint, increased rapidly in size, and seemed to be the principal channel of communication with the arteries of the leg.

I might mention that, within twenty-four hours after the solidification of the tumor, the œdema in the leg had entirely disappeared; and the pain had become so much less that the patient was able to relinquish the further use of the opiate, to which he had resorted to obtain relief.

Rockville Centre, L. I., *March 15th*, 1876.

Reports of Hospitals.

BELLEVUE HOSPITAL.

Notes of Practice and Peculiarities of Treatment.

INFANTILE PARALYSIS.

These cases were interesting simply from the fact that there was so slight constitutional disturbance after the attack. One baby, twenty-two months old, born of healthy parents, but itself rather delicate, was put in bed at night five weeks ago, and the next morning was found unable to either sit or stand. The child was a trifle feverish for a few days only. The left leg had been restored, but the right exhibited a marked degree of motor paralysis. The temperature of the paralyzed leg was 3° F. less than the other. The other baby, eighteen months old, born of healthy parents, and itself always healthy, was placed in bed at night four weeks ago, and the morning following, was found unable to stand, but the paralysis affected the left leg only. There was about the same difference in temperature between the right and left leg as in the other case, but the paralysis was more marked. The constitutional disturbance which followed the attack in this case was so slight, if there was any, that it was not noticed.

CERTAIN PECULIARITIES OF A DISEASED ANKLE-JOINT.

The case illustrated how much damage may follow a very slight injury of a joint, in the event that it is not properly treated after the occurrence of the accident. A man, æt. 40, hale and healthy, and weighing 270 pounds, "sprained his ankle" about two years ago; but the injury was so slight that it passed almost unnoticed, and gave him no great inconvenience, except when over-exercised, or slightly twisted, etc. As time passed along, the joint began to enlarge, and at the time of the examination it was seventeen inches in circumference, the extra size being produced by the inflammatory deposits which had been thrown out, simply because the subject was a vigorous, healthy man; whereas, in a weakly, broken-down constitution, the same amount of disturbance would probably have terminated in caries. The disease in this case was undoubtedly of traumatic origin. The instant the joint surfaces were crowded together, the patient complained of pain. The point in the treatment, therefore, was to relieve these surfaces of all pressure, which was accomplished by means of the splint commonly used by Dr. Sayre in the management of this class of cases.

LATERAL ROTARY CURVATURE OF THE SPINE—SUBCUTANEOUS SECTION OF THE LATISSIMUS DORSI MUSCLE.

The interest in this case centred upon the fact, as was stated, that it was the first time, probably, that the latissimus dorsi muscle had been cut for the relief of a deformity. The patient was a young man about twenty years of age, whose occupation obliged him to carry a loaded basket upon his shoulder. Upon accurate measurement, it was found that his right leg, for some reason unknown, was about ¾ of an inch shorter than the other, which permitted the pelvis to tilt and form a starting-point for the development of a spinal curvature, and that had been increased by his occupation. It sometimes happens that muscles engaged in the production of a deformity, when the tension has been strong and long-continued, undergo such structural changes as renders rupture or section necessary before the distortion can be overcome. When, therefore, this young man was suspended by means of apparatus which hung him from the arm-pits, and the latissimus dorsi muscle of the left side was brought out like a tense, unyielding, fibrous band, point pressure was made upon it while in this stretched condition, and pain and spasm were produced which decided the question at once that it could not be overcome without RUPTURE OR SECTION. Prof. Sayre, preferring the latter, divided the muscle subcutaneously while the patient was suspended, and the weight of the body at once overcame the curvature to a very great extent, and the tense band that rode up under the finger before the operation almost entirely disappeared. The wound was quickly closed with adhesive plaster and secured with a roller bandage. Of course, it was not practicable to keep the patient suspended for any considerable length of time, hence he was placed upon a bed, and the indications fulfilled as best they could be while in the horizontal posture. This was done by passing a rubber-band about the hips, and then fastening it to some object upon the left side of the body, and also a second band around the trunk above the point of section, which was to be secured to something immovable upon the right side. One week after the operation the patient was doing well, and was soon to be placed in the

plaster-of-Paris jacket. The final result in this case was very satisfactory.

WELL-MARKED TYPHOID FEVER — THERMOMETRICAL VARIATIONS — EFFECT OF TREATMENT UPON THE TEMPERATURE AND THE GENERAL CONDITION OF THE PATIENT.

The following case illustrated two or three points of interest and great practical importance, chiefly relating to the use of cold as an antipyretic.

First, the case furnished an excellent illustration of the statement, that the axillary temperature does not give a fair representation of the temperature of the body when the patient is first removed from the bath. It may be well to state that the only antipyretic employed in the management of the case was cold, in the form of the cold bath, and this measure was resorted to whenever the temperature was above 103° F.

The unreliability of axillary temperature was demonstrated as seen below. The patient was admitted Oct. 10, and up to Oct. 14 the temperature was taken only in the axilla; after that date it was taken both in the axilla and in the rectum. The average temperature of the baths given was 70° F., and the average duration was *five minutes*, and this is important to note, because it has a bearing upon another statement soon to be made.

Oct. 13th.—Previous to receiving a bath, the temperature in the rectum was 103° F., and in the axilla 103⅘° F.

After a bath, given of the temperature and duration noted, the temperature in the rectum was 103° F., but in the axilla the thermometer stood at 97⅘° F.

Within two hours the axillary temperature had risen to the same degree as noted in the rectum. As a rule there was not much variation between the axillary and rectal temperature independent of the effect produced by the bath, but at 2 A.M., Oct. 14, the rectal temperature was 104° F., and the axillary 105° F. At 9 A.M. the rectal temperature was 104⅘° F., and the axillary 104¼° F. The patient was placed in a bath, and immediately after being removed, the rectal temperature was 104° F., while the axillary temperature was 101° F. At another time a bath of five minutes' duration, and temperature of about 70° F., was given, and the record immediately after removal showed respectively, rectal 104½° F., axillary 101½° F. These are fair selections from a goodly number of observations made, for a bath was given six or seven times a day up to Oct. 17, all of short duration, and *without* producing marked diminution in the temperature of the body as taken in the rectum. There were several observations made which corroborated the statement, that the *first* effect of a cold bath is to increase rather than diminish the temperature *within* the body.

The case beautifully illustrated another statement now to be made, namely, that the effect desired, a reduction of the temperature *within* the body, is not obtained by a bath of short duration, for it was only when the bath was *prolonged* that any marked effect upon the rectal temperature was produced.

To illustrate: on October 17th a different method of giving the cold bath was introduced. It was prolonged, and the water was gradually cooled to 65° F. At 9.15 A.M., October 17th, the temperature in the rectum was 104⅘° F., and in the axilla 103¼° F. The patient was placed in a bath of 80° F. At 9.40 the rectal temperature was 104⅘° F.; at 9.50, still in the bath, now cooled to 65° F., the rectal temperature was 101° F.; at 10 o'clock, rectal temperature 101¼° F. and bath still at 65° F. The patient, now complaining considerably of cold, his teeth chattering, etc., was removed from the bath and received a small amount of whiskey.

At 10.22, twenty minutes after removal, the rectal temperature was 102⅘° F., and at 11.30, 101° F. At 12.40, the rectal temperature was 101¼° F., and at 1.40 it had again reached 104° F.

At 2 P.M., when put into a bath, the rectal temperature was 104⅘° F. The bath was cooled down to 65° F. in fifteen minutes, and the thermometer in the rectum stood at 105° F. At 2.35, with the bath at 65° F., rectal temperature at 104½° F. and a duration of thirty-five minutes; the patient was removed, and ten minutes after the thermometer in the rectum indicated a temperature of 104° F. At the end of one hour the temperature was 103⅘° F., and the bath was again resorted to and prolonged for half an hour, and when the patient was removed his temperature stood at 105° F. Ten minutes after removal it had fallen to 104° F., and forty-five minutes after removal it was down to 102¼° F. These also are sufficient selections to illustrate the statement, but it will be observed in addition that no material fall in temperature took place while the patient was *in* the bath, just the opposite occasionally, but that soon *after* removal from a prolonged bath the temperature began to decline, and continued to do so for some hours.

The other peculiarities of the case were:

1. Absence of prominent abdominal symptoms.

2. Absence of delirium, which is a rare circumstance in a case of considerable severity and characterized by high temperature.

3. The patient did not take to bed until after admission; the characteristic eruption appeared two days after admission, which showed that the disease was seven or eight days old, hence the fever must have commenced four or five days before admission. In this fact, then, lies an exception to or a case in evidence against the statement that the beginning of the disease should be reckoned from the date of taking to bed.

TEMPORARY ATTACKS OF APHASIA — LOSS OF POWER IN THE RIGHT ARM.

This case was worthy of note for the two items indicated.

A man, æt. 60 years, had two slight attacks of pleurisy three or four years ago, but aside from these had always been healthy until about two years ago, when he began to suffer more or less pain over the region of the sternum, and has also suffered somewhat from shortness of breath, especially on going up stairs. A few days ago, while sharpening his razor, he suddenly discovered that he was unable to speak, and about fifteen minutes elapsed before his power of speech returned. It was difficult to determine whether he could move his tongue or not at the time of the loss of ability to speak. There was marked loss of power in the right arm, but the leg remained unaffected. This attack was one of quite a number from which he has suffered. About a year ago he had a similar attack, which occurred about four o'clock in the morning. At that time he was unable to speak, but was able to move the tongue; his face was slightly drawn to the left side, but there was no trouble with the leg. The inability to speak soon passed away. Six weeks afterwards he had another attack while walking across the street, became paraplegic, the right arm became very much crippled, and he was also unable to speak. This attack lasted about two hours, and then passed away. His last attack has been described. The man did not

suffer from headache, protruded the tongue correctly, and had the slight loss of power in the right arm already mentioned. Sensation was unimpaired. It was believed that these attacks were due to embolism. The man had valvular disease of the heart.

VALUABLE POINT IN PHYSICAL DIAGNOSIS.

The point relates to pulmonary resonance over the sternum. The edge of the right lung reaches to the *centre* of the sternum, as can be determined by *light* percussion. When the person is made to take a full inspiration, and hold it, pulmonary resonance can be easily detected entirely across the sternum. Some of the books teach that dulness upon percussion is normal over the sternum, hence the practical inference that when resonance is obtained over this region some abnormal condition is present, which is not necessarily true.

INJECTION OF STIMULANTS INTO THE TRACHEA BY MEANS OF THE HYPODERMIC SYRINGE.

The patient was in a condition of collapse. About one drachm of a fluid, consisting of equal parts of water and brandy, was thrown slowly into the trachea by means of a hypodermic syringe, the needle of which had been thrust through its walls. The patient did not rally, but no ill effects were produced, nor inconvenience given.

The inner surface of the trachea is said to absorb volatile substances more rapidly than any other surface in the body.

ITEM OF INTEREST IN A CASE OF CHRONIC HEART DISEASE.

A noticeable feature of this case was the presence of well-developed valvular disease and hypertrophy with dilatation, without any history of rheumatism or syphilis, in a young man, æt. 23 years.

The case in addition illustrated the occurrence of Bright's disease secondary to cardiac disease, and at the time of the examination he was also suffering from pleurisy with effusion.

CERTAIN PECULIARITIES IN A CASE OF PNEUMONIA.

One or two points of interest were noticed in connection with a case of this disease occurring in a young man, æt. 25. He had been "on a spree," got wet, went to bed with his wet clothes on, and awoke with a chill. The severity of the pleuritic pain was a marked feature of the case, but a peculiarity was noted in the fact that it did not come on until some six or eight hours *after* the chill. Upon the day of admission his temperature was 105⅘° F., and he received thirty grains of the sulphate of quinine. The next morning his temperature was 104° F., and twenty grains were administered. The following morning the thermometer stood at 101¼° F., and only five grains were given, and the morning after the temperature was normal. Good diet and a moderate amount of stimulants had also entered into the general treatment. There was one item of local treatment which may be worthy of note. The pleuritic pain had been unusually severe and unusually prolonged, and the characteristic expectoration had also been continued for some time after the second stage was well developed. For the relief of the intense pleuritic pain, compresses wrung out of cold water had been employed for three hours faithfully, but they afforded no relief whatever. This was not, perhaps, a fair test of their efficacy in relieving the pleuritic pain of the early stage of the disease, for the case had been one of some days' standing when the measure was employed. A hypodermic injection of morphine was administered. In addition, the chest was to be firmly strapped with strips of adhesive plaster over the region where the pain was located, and this was done to prevent, as much as possible, the inflamed surfaces of the pleura from rubbing against each other. The strapping gave great relief.

There is a point in physical diagnosis which the case illustrated, namely, the possibility of determining from the percussion note obtained over the anterior portion of the chest which lung is affected posteriorly by the consolidation. The vesiculo-tympanitic percussion note is to be expected over the portion of lung unaffected by the inflammation, and in this case it was very well marked over the right lung anteriorly. Over the lower lobe of the right lung, *posteriorly*, bronchophony, bronchial breathing, and dulness upon percussion were well marked.

NEW IDEA RELATING TO CHANCROIDS AND STRICTURE OF THE RECTUM.

The interest in two cases which were seen centered upon the fact that they were illustrations (1) of the ease with which chancroids inoculate themselves, and (2) that stricture of the rectum may be a final result. Both patients were females. One showed chancroids near the meatus urinarius, in the fourchette, upon hemorrhoidal growths which were present around the verge of the anus, and the effects of the virus were plainly seen within the cavity of the rectum. When the rectum is reached troublesome ulceration becomes developed, and, as a result of this stricture, which was well illustrated in the second patient.

They were regarded as more typical cases than are usually seen. These strictures are often spoken of as syphilitic strictures of the rectum, but it was believed that, in a very great majority of cases, they are of *chancroidal* origin. In a large percentage of cases at least there is no constitutional syphilis present, or evidence of its previous existence. The patient with stricture before us gave no history of constitutional syphilis, but there were well marked chancroidal cicatrices present and a history to sustain them.

Something, it was said, could be done to prevent the spread of the disease up the rectum, and in this case nitric acid was applied, and the ulcers subsequently dressed with iodoform. Such strictures for obvious reasons are not of common occurrence in the male subject.

WATER-LOGGED.

The patient was a victim of chronic Bright's disease, and in his dropsical condition weighed 250 pounds, but when he went out of the hospital he weighed only 130 pounds.

CHRONIC BRIGHT'S DISEASE—LOCALIZED PLEURISY.

In this patient these two conditions were present, and it was remarked that the latter was a very frequent accompaniment of the former in its *earlier* stages.

OCCASIONAL RESULT OF ŒDEMA.

A male patient suffering from Bright's; had extensive œdema of the lower extremities, and the result referred to was that the legs remained of their great size after the man felt well enough to leave the hospital and go to work. The legs felt like a log, and could scarcely be made to pit upon pressure.

SOLE-LEATHER SPLINTS—AMMONIA-WATER.

Sole-leather softens much more readily when placed in cold water if a small quantity of aqua ammonia is

added. A drachm to the quart is perhaps sufficient, and will soothe the surgeon's patience as well as soften the leather.

HOT WATER AS AN AGENT FOR BRINGING ABOUT RELAXATION OF CONTRACTED MUSCLES.

The case illustrated in a striking manner the effect which is sometimes produced upon contracted muscles by the use of hot water. The water was poured upon the contracted parts for a considerable length of time at each sitting and repeated twice a day.

When this measure was first resorted to in the case before us, the knees were held forcibly in contact with each other, and the heels were in close contact with the nates.

The man is now able, at the end of little more than one year, to separate the knees about eighteen inches, and can sit in a chair with his feet upon the floor. This relaxation is more than temporary, for the reason that it continues beyond the time in which the muscles are under the immediate influence of the hot water.

ELEMENTS IN THE DIAGNOSIS OF SYPHILITIC HEMIPLEGIA.

The patient, a man æt. 35, was thought to have syphilitic hemiplegia for the following reasons:

1. Hemiplegia occurring under the age of forty, if embolism can be excluded, is presumably syphilitic, and the presumption increases in strength in proportion as the age grows less.

2. In syphilitic hemiplegia chronic headache is a prominent feature, both preceding and following an attack, and is usually worse at night.

3. Syphilitic hemiplegia almost invariably occurs without loss of consciousness.

There was a doubtful syphilitic history in this case, yet no secondary manifestation could be traced. That fact, however, led to the *fourth* observation, namely, that where the nervous system is secondarily involved by syphilis, other secondary manifestations, such as roseola, sore throat, etc., etc., are only very slightly, if at all, developed.

Again, if there is a second attack of hemiplegia soon after the first, but affecting the *opposite* side, it was believed to be almost absolute proof that the first attack was syphilitic. The patient was placed upon iodide of potassium gr. xx. t. i. d., to be gradually increased until six drachms are taken daily, if necessary, to effect an improvement. For the headache, gtt. xv. of the fl. ext. conium (Squibb's) were added, for it was said to have the power of prompting the action of the iodide, and will give relief in cases where the potassium alone has failed. At the end of two weeks this man's headache was very much relieved.

PROBABLE UNION OF THE AXIS AND ATLAS—SYPHILITIC HISTORY—MOTION RESTORED BY MEANS OF HYPODERMICS OF MERCURY.

The case was interesting as illustrating one point, namely, the value of local treatment by means of the hypodermic syringe, as compared with the results obtained by administering the same remedy by the mouth. The man was unable to perform any movements of the head which are permitted by the motility existing between the axis and atlas, nor could he make a bow with any commendable degree of suppleness. From the fact that he had a syphilitic history, it was suspected that his stiff neck was one of the results of that disease, consequently iodide of potassium and mercury were administered in varying doses by the mouth, but without producing any apparent benefit. He was then treated by the use of hypodermic injections of the bichloride of mercury in the nape of the neck, and improvement was immediate and marked. The movements of the head were almost completely restored. The mercury was given in one-thirtieth grain doses, once a day.

ASTHMA—HYPODERMICS OF ATROPINE.

This was a case also that had proved rebellious while using the ordinary remedies by the mouth, but yielded very readily to one-fortieth grain doses of the sulphate of atropia, administered hypodermically in the nape of the neck.

Progress of Medical Science.

ACTION OF THE BILIARY SALTS ON THE PULSE, ARTERIAL TENSION, RESPIRATION, AND TEMPERATURE.—MM. Feltz and Ritter have found that injections of bile into the blood in non-toxic quantities cause a reduction in the frequency of the pulse and respiration, and a diminution of temperature and arterial tension. Injections of the coloring matters of the bile alone, or of etherial solutions of the cholesterine, do not produce these functional disturbances, but injections of moderate doses of solutions containing the glyco-and taurocholate of soda, in the proportions in which they exist in the bile, do produce them. The action of the biliary salts is exercised primarily on the blood, and through it on the muscular system; in fact these functional disturbances are produced even when the pneumo-gastric and great sympathetic nerves have been previously divided. The action of the biliary salts on the muscles is further marked by a rapid exhaustion of muscular contractility. Blood contaminated by even hardly appreciative quantities of the biliary salts flows more slowly through the capillaries than the normal blood. This reduction of velocity is manifestly due to the action of the biliary salts on the red globules, though the latter may show no evident change; for if the serum of the blood, and defibrinated blood be treated by the same agents and placed under identical conditions, the former shows no sensible retardation in flowing through the tubes of Poiseuille.—*Gazette Médicale de Paris*, March 18th.

WEIGHT OF NEW-BORN CHILDREN.—Ingerslev, of Copenhagen, finds as the result of his researches upon this subject, that every child loses weight during the first days of extra-uterine life. An increase may occur on the first day, if the meconium have escaped during birth, or if it have not been discharged before the first weighing, and the child have sucked in the meantime. This increase is only transient, and the loss of weight shows itself at the second and third weighings. The loss corresponds to one-fourteenth or one-fifteenth of the body-weight, and is both absolutely and relatively greater in the children of primiparæ. As for the original weight of the body, the loss is greater the less developed the child is, and in the same proportion the increase is more delayed; premature children show a corresponding relation. The increase begins as a rule on the fourth day. As regards the conditions having an influence on the loss, no connection can be found between the detachment of the umbilical cord and the commencement of the increase; but the chief importance must be attached to the relation between the egesta and ingesta. The loss cannot be explained

by the discharge of meconium and urine alone, for not more than half of these correspond to the loss of weight in a given time. The remainder of the loss must be ascribed to a consumption on the part of the child, and at first sight too small an amount of ingesta, or defective nourishment, might indeed be regarded as the cause of this; but as abundant a supply of food as the child can use does not compensate for the loss. The consumption of tissue and the consequent loss of weight are a physiological necessity.—*The Obstetrical Journal*, March, 1876.

Systemic Infection from Purulent Vaginal Discharges.—According to Dr. E. T. Easley, it is probable that septicæmia may supervene on a profuse and persistent leucorrhœa, and absorption in such cases takes place through the vaginal walls as well as other mucous surfaces. The reasons that lead him to this view are, in the first place, that endosmosis depends upon the attraction of the membrane for the liquids, and its current in mucous membranes is found, in accordance with their physiological action, to be from the exterior to the interior. The more minute and extensive the vascular supply of a membrane the larger, of course, will be the endosmotic surface presented. In the second place, the transudation in facility and rapidity bears an inverse ratio to the thickness of the epithelia; but thirdly, the fuller and more tense the vessels of a part are, the more difficult will be the process of absorption; and, converse, ly, a rapid movement in the capillary blood, with diminished tension of the vessels, greatly favors the reception into the circulation of matters fit for absorption. The vagina is among the most highly organized structures in the human economy, its vascular, lymphatic, and nervous connections being in immediate relation with those of the other pelvic viscera. This shows obviously the liability of extraneous matters from the vaginal walls being absorbed into the circulation, more particularly when these walls are in an unhealthy condition. It may be safely said, that a vaginitis attended with profuse yellow leucorrhœa, is certainly evidence of more or less extensive abrasion of the mucous epithelia of the genital canal, hence the readiness with which putrid or broken-down products may be taken up.—*The Medical and Surgical Reporter*, April 1, 1876

Complete Extirpation of the Larynx.—Another case in which the larynx was completely removed by operation is reported by Prof. Maas, of Breslau. The first signs of trouble in the larynx showed themselves at the end of September, 1873. By the middle of the following April, the patient, a man of 57, suffered so much from the stricture of the larynx caused by the large and growing tumor, that tracheotomy was performed by Dr. O. Riegner. By the first of June, however, the tumor came to press so much upon the œsophagus that it was impossible for the patient to swallow the smallest portion of fluid. The operation of extirpation of the larynx was therefore performed by Prof. Maas, who found great advantage in adapting a modification of Rose's position, with the head hanging backwards. After the operation the patient found the frequent introduction of the œsophageal tube so painful that Prof. M., on the third day, passed an India-rubber tube through the wound, down nearly to the cardiac end of the œsophagus, and left it in that position. Through this the nutrition of the patient was satisfactorily carried on. On the ninth day he was able to leave his bed; on the eleventh an unsuccessful attempt was made to introduce an artificial larynx; on the twelfth the bronchitis, from which he had suffered since the tracheotomy, became seriously worse, and on the fourteenth day he died of pneumonia. The microscope determined that the tumor which involved the whole larynx was adeno-fibroma carcinomatosum.—*Langenbeck's Archiv, XIX*, 3. 1876.

Resection of the Larynx—Prof. C. Heine, of Prague, reports a case which he diagnosticated as concentric hyperchondrosis of the larynx, and which resulted in almost complete obliteration of the cavity of that organ. Tracheotomy had been performed, with temporary relief, also a subsequent dilatation of the fistula; but the case became so urgent that, on December 18, 1874, Prof. H. performed an operation which he designates as resection of the larynx. It consisted in splitting the thyroid cartilage in the median line, and then making a sub-perichondrial dissection of the anterior halves of the two sides, and removing them with forceps. The operation was so far successful that the patient regained the power of speaking intelligibly, and of swallowing liquids and solids. Subsequently, however, his condition deteriorated, and he succumbed to tuberculosis on November 2, 1875. At the autopsy, syphilis, which had been suspected, but denied, was proved to have been at the root of the laryngeal disease.—*Langenbeck's Archiv, XIX.*, 3, 1876.

Comparative Statistics of Trephining in Wounds of the Head.—Dr. Bluhm, of the Prussian army, furnishes the following table of the mortality after trephining for gunshot and other wounds of the head, arranged according to the period at which the operation was undertaken:

Trephining.	In General.	In Gunshot Wounds.
Primary	55.26 per cent.	64.29 per cent.
Secondary.....	39.24 " "	42.86 " "
Late.....	33.90 " "	11.11 " "

Thus, in other than gunshot wounds, a progressive improvement in the result of trephining is observed, according to the length of time that has passed since the receipt of injury. In the case of gunshot wounds, on the other hand, while the result of primary and secondary trephining is more unfavorable, the late operation gives very much better figures.—*Langenbeck's Archiv, XIX.*, 3, 1876.

A New Series of Lithotomy Cases.—In a paper read before the Georgia Medical Association, Dr. W. F. Westmoreland furnished a brief synopsis of thirty-seven cases of urinary calculus, which came under his personal observation. In thirty-four of the cases in which the stone was removed from the bladder, the operation was done by lateral lithotomy in thirty-three, and in all but one case the section was made with the lithotome. As for lateral operations, Dr. W. states that any surgeon, whatever may be his skill, will always operate best with instruments that he is accustomed to use, and by the method with which he is most familiar; while he is assured that statistics have demonstrated the fact that surgeons who have adopted the lateral method can present as brilliant a series of lithotomies as others operating by other methods. If he tabulated his results, and withdrew two cases in which he had operated under protest, there would have been only one death in thirty-two cases,—a result of which he may justly be proud.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

New York, April 22, 1876.

STATE BOARDS OF HEALTH, AND A NATIONAL HEALTH BUREAU.

When we appreciate how much has been accomplished by local health boards in the improvement of the sanitary condition of the communities living under their jurisdictions, we are impressed with the necessity of utilizing their good offices to a larger area of country. It is true that the public are beginning to acknowledge the benefit which a well-managed health board can confer in systematizing measures for the prevention of the spread of disease, and of enforcing sanitary ordinances in times of emergency; but more than this is required. Increased knowledge of sanitary requirements will eventually prepare each community throughout the country, not only for quiet submission to sanitary laws by government officers, but will cause them to ask for their enactment by their law-givers. Thus far, only some of the larger cities are blessed with efficient sanitary boards, while many of the smaller towns are entirely without any such provisions. In the meantime, however, something must be done towards shaping the necessities of the people, and devising some plan which shall meet the present urgent want. Popular sentiment must not only be encouraged, but must be led into the channel of practical usefulness.

Every practical sanitarian is aware of the fact that there is no town, village or hamlet which cannot be benefited by suitable sanitary regulations; none in which the death rate could not be diminished, and the prevention and spread of epidemic diseases could not be brought under the influences which our present knowledge of epidemology has made available. How often do we hear of epidemics in small towns and in country districts, which are known to be due to causes within the control of proper sanitary measures? And yet, for the power to enforce them in the shape of a legally authorized board, nothing whatever can be done to save precious lives. When we take into account the large number of the small villages and towns throughout the country, and consider the practical impossibility, for the present at least, of creating sanitary bureaus for each, we are naturally forced to the conviction that the only possible way to serve the interests of all, and insure proper attention to health matters, would be the establishment of some general system, of which each of these smaller places should be a part. Taking this, then, as the starting-point of some suggestive remarks, we may follow it in a general way through all its legitimate ramifications until it shall centre, if possible, in a national bureau, which shall be one of the departments of the general government. How such a system can be made a perfect one, has been a problem to which much attention has been directed, and concerning which many fruitless attempts at legislation have been made. It will probably be a long time before any plan will be settled upon which shall satisfy the general requirements of the country, and meet the approval and command the support of the people at large. Whenever any measure is proposed calculated to give a practical turn to the idea, there is so much of political jobbery infused into it, that it is soon apparent to every one that there is more concern for the creation of offices for the benefit of the agitators of the reform, than a desire to consult the public interests or minister to its welfare. The difficulties in the way should not, however, interfere with a discussion of the subject, nor thwart the legitimate and reasonable efforts towards the much-desired result.

One of the truly practical methods of overcoming many, if not all of the difficulties, is to so simplify the system as to make it consistent, feasible, and economical. As a contribution to this part of the general subject, some suggestions which occur to us may be worthy of consideration.

It would appear that the first step which we can take is the utilizing of the means already at our command, in amplifying, so to speak, the powers of our local boards. In many of the large cities of this State we have local boards which, in their way, are doing all that can be expected of them. Let us take them, as starting-points of a general system of sanitary regulation throughout the State, the establishment of a State Board of Health. The idea will at once suggest itself that this State Board can be composed of members from the local boards; for instance, one from each. The realization of such an idea is, in our opinion, the only practical way of overcoming the main difficulty in the case.

The question of economy which naturally comes up in connection with this measure, may be easily and satisfactorily answered. The delegate from a local board need not have any extra allowance other than that for ordinary travelling expenses.

The necessity for that centralization of power which shall make the general board effective and its doings authoritative, suggests the appointment of an executive officer. We care not how he be selected from the board provided he have the proper qualifications. As the major part of the work must necessarily fall on this officer, he should receive a salary sufficient to enable him to devote all his time and energies to his duties. While this plan of organization might be practicable in this State, we are aware that in other States some modifications might be necessary. The general principle, however, could be carried out so that the local and general boards of each State would be dependent on each other. When the State Boards shall have been created throughout the Union, the foundation will then be laid for a Central Bureau of Health as a distinct department of the general government. The same relation should be maintained between the general Bureau and the State Bureau as between the latter and local boards, constituting a system harmonious in all its parts, and thoroughly impartial in its aims.

THE ARMY MEDICAL RANK BILL.

Under present circumstances, there is not a very brilliant prospect for the Army Medical Rank Bill. It is true it has passed the Senate and the Military Committee of the House; but there are difficulties in the way of its final success which are quite formidable in their nature. Probably to the bill itself there would be no particular objection, but in the proposed report of the Committee it is so mixed up with other matters which bear upon appropriations, that there is a chance that much unnecessary prejudice may be brought against it, which may in the end defeat the whole scheme. Why cannot the House Committee report the bill by itself? The matters with which it is now associated are not even legitimate side issues. The medical profession of the United States have given a great deal of attention to the subject of relative army rank; and it is but just to them that the question involved in the bill should be placed upon its own merits.

CHANGES OF RESIDENCE AND SANITARY NECESSITIES.

At this time of the year, when the moving portion of the population are engaged in hunting up new quarters, the necessity of looking after sanitary requirements cannot be too strongly urged. In a large majority of the houses "to let," there are the seeds of future disease and possibly death for various members of the incoming families. The drain pipes are in many cases defective, the water-closets are in some of the best houses very little attended to, while the cellars are very apt to be filled with all sorts of decaying material, to be unventilated and to imprison the poisoned vapors of defective drainage. And yet, how few of the "House hunters" take these things into account?

QUARANTINE SELF-SUPPORTING.

We hope that the bill before the Senate proposing to make quarantine self-supporting will become a law. The fees which have been collected by the Health Officer are altogether out of proportion to the public or professional services rendered, and should be abolished. Although we have reason to believe that the present Health Officer has been honest in all his dealings, the facilities for wrong-doing are too many and too strong for the ordinary office-holder to resist. The salary for the Health Officer, proposed in the bill, is amply sufficient, and will secure the services of competent professional men. A synopsis of the bill is presented in another column.

Reports of Societies.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, April 6, 1876.

Dr. S. S. Purple, President, in the Chair.

ON THE CAUSE OF ROTATION IN LATERAL CURVATURE OF THE SPINE.

Dr. A. B. Judson read an interesting paper upon the above subject, in which he presented the views of nearly all authors who have written upon the question of rotation of the vertebræ in lateral curvature, and it was found to be a well-recognized fact that lateral curvature of the spine had that peculiarity in all cases, except those which were developed in connection with pleurisy. In that class of cases the rotation was either absent or only very slight.

The cause of that rotation had engaged the attention of Barwell, Adams, Shaw, Holmes, Bigelow, Dick, Bauer, Meyer, Bell and others, and had elicited almost as many explanations as there were authors. After reviewing the explanations given by the authors referred to, the author of the paper proposed the following explanation—namely, that rotation of the vertebral column was caused by the muscular and fibrous structures attached to its spinous processes, which kept those processes near the median line of the trunk, while the bodies of the vertebræ, being devoid of attachments, were moved to one side of the median line.

The doctor then referred in detail to the muscular and ligamentous attachments of the vertebræ; and it was found that the anterior portion of the vertebral column was almost entirely free from attachments, leaving the bodies of the vertebræ free from control, while the posterior portion of the column was held near the median line by attachments to which reference had already been made. Speaking geometrically, the author of the paper claimed that the rotation in the case in question was upon a remote axis. The chief feature of the explanation was the recognition of the fact that the posterior portion of the vertebral column was firmly bound to the walls of the trunk, while the anterior portion was left to move to the right or to the left, according to the direction of the curve.

It could be seen that the author of the paper did not attribute the rotation to disparity between the action of single muscles or groups of muscles, but recognized the combined action and sustentative power

of all the muscles and ligaments upon either side of the trunk.

Dr. Judson demonstrated his theory by means of an articulated vertebral column, suspended in a frame in such a manner that pressure could be brought to bear upon the top of the column. The articulation was effected by means of a brass strip, perhaps one-fourth of an inch in width, very flexible, and the spinous processes were attached to the sides of the frame by means of metallic strips or wires, which represented the attachments upon the human trunk for retaining those processes nearly in the median line.

Now, when pressure was made upon the top of the column, it was seen that the spinous processes were held nearly in the median line, while the anterior portion of the vertebræ rotated to a greater or less extent, and in a direction corresponding to the degree of curve made in the column by the pressure from above. Rotation of the bodies of the vertebræ, it was remarked, had been regarded as an obstacle to the restoration of the vertebral column to its proper form. It was maintained, however, that mechanical treatment was beset with difficulties, not so much from mechanical displacement, but because the portion of the column which deviates farthest from the normal line cannot receive direct mechanical support.

Transmission of weight from the anterior portion of the vertebræ, by means of support applied to the posterior portion of the spine was suggested as an element which should enter into the construction of any apparatus, or the adoption of any measure for the treatment of this affection.

Prof. Sayre regarded the explanation which Dr. Judson had given for the rotation present in lateral curvature of the spine as exceedingly plausible: and that, apparently, it had been completely demonstrated. He drew special attention to the principle of treatment which had been brought forward by Dr. Judson, and which had not heretofore been adopted, namely, removal of compression of the spinal column from above downwards, if a perfect cure was to be most readily effected. He was the more pleased with this idea, because it explained to him how it was that such benefits had followed the use of the plaster-of-Paris jacket, which he had been using for some time past in the treatment of Pott's disease of the spine, and latterly in the treatment of rotary lateral curvature. Prof. Sayre then referred, somewhat at length, to his use of the plaster jacket in the treatment of both of these affections, what first induced him to resort to it, how it was to be applied, etc. He had used it in four cases of rotary lateral curvature, in three of which he had made section of the latissimus dorsi muscle; and in all of his cases, the treatment had been attended by remarkable success. For Pott's disease he had applied over one hundred and thirty plaster-jackets.

Correspondence.

MEXICO AS A RESIDENCE FOR INVALIDS.

Letters from Prof. E. R. PEASLEE, M.D.

I.

Hotel Iturbide, City of Mexico, *March* 12, 1876.

Mr. Editor:—While awaiting my breakfast this morning, it occurs to me to give the readers of The Record some facts respecting this city and some other places in Mexico, as a residence for invalids from the North. I will, however, at this sitting, explain how this capital may be most easily reached from New York, and answer some of the questions which may naturally arise respecting the incidents of such a trip.

1. If the traveller is not averse to a sea voyage all the way from New York to Vera Cruz, he can leave for the latter port every twenty-one days, in one of F. Alexandre & Sons' steamships, which reach Havana within five days, without any intermediate stop. Remaining there two days, they run, in about thirty-six hours, to Progreso, in Yucatan, to remain one day; thence, in twelve hours, to Campeche, in the State of Campeachy; whence, after a stop of twelve hours or less, they arrive at Vera Cruz in thirty-six hours more. This makes the trip from Havana to Vera Cruz also about five days, and the whole time thither from New York twelve days or less.

This line consists of six excellent steamers, of from 1100 to 2000 tons, all of which sail from New York to Havana, one leaving each week; but only three of them go on from Havana to Vera Cruz, viz: the City of Merida, City of Havana, and City of Mexico; and it is one of these which leaves New York once in three weeks, as before stated. If, therefore, the tourist wishes to spend one or two weeks at Havana, he will go there on one of the other three ships of the line, viz: the City of New York, City of Vera Cruz, or the Cuba, and take the steamer to Vera Cruz when it arrives at Havana from New York.

2. But if the sea is to be as far as possible avoided, the following route may be adopted, and was so by myself: The steamers above named, as sailing from New York to Vera Cruz in twelve days, remain five days at Vera Cruz, and then sail for New Orleans, making this trip in five days also. They touch (but do not land) at Quxpan and Tampico, on the way to New Orleans. Thus, the trip from New York to New Orleans, via Vera Cruz, is accomplished in twenty-two days. Remaining five days at New Orleans, these three steamers now retrace their course back to New York, calling at all the places I have mentioned, in the inverse order in which I have named them. The times are also the same as before; *e. g.*, the City of Merida, on which I sailed, is five days in going from New Orleans to Vera Cruz, including the stops at Tampico and Quxpan; remains five days at Vera Cruz; is five days on the trip thence—stopping at Campeche and Progreso—to Havana; remains there two days, and reaches New York in four to five days more. To reduce the sea voyage, therefore, to Vera Cruz to a minimum, the invalid will go to New Orleans from New York by land, which can be accomplished by four distinct routes in seventy-two hours, or less, and then by sea to Vera Cruz in five days more; or eight days from New York. If the route from New York to New Orleans by Louisville and Milan—the "Great Jackson route"—or that by Lynchburg and Atlanta—the "Kenesaw route"—be taken, there is but one change of cars on the way, viz: in Louisville, on the former route, and at the Relay House, seven miles beyond Baltimore, on the latter. Having travelled over both these, and found them both excellent, I would advise the tourist to select the one which carries him through those parts of the South which he most desires to see. On the other two routes to New Orleans, viz: the "Coast Line," through Richmond, Wilmington Charleston and Savannah, and the "Piedmont or Air Line," through Richmond, Danville and Charlotte to Atlanta, where it meets the Kenesaw route, the traveller changes from the sleeping car by night to the common car by day. The trip may be still further varied by going by land to Cedar Keys (Fla.), and by steamer thence to Havana in two and

a half days. I expect to return by that route; *i.e.*, from Vera Cruz to Havana, thence to Cedar Keys, and by land to New York.

Arrived at Vera Cruz, the tourist who has taken his ticket for the round and rapid trip, has five days in which he may visit this city and some other places, and return to take the same ship to Havana or another to New Orleans, according to his destination. Or he may remain in the interior, and take the next ship of this line in twenty-one days, on the same ticket; or leave Vera Cruz for Havana direct on a French steamer, on the 18th of each month, or by an English one about the 1st of each month.

There is but one passenger train daily each way over the railroad from Vera Cruz to this city, leaving Vera Cruz at 11½ at night and Mexico at 10½ at night, and arriving in this city at 6½ in the evening and at Vera Cruz at 3½ P. M. Just now, on account of revolutionary disturbances, the trains are run through more rapidly, and mostly by daylight, leaving Vera Cruz at 4 A. M. and this city at 5 A. M. The whole length of the railroad is 263½ miles, and the run up is made in sixteen hours and down in fifteen. The cost of the road was $30,000,000. The first 26 miles out of Vera Cruz is almost a dead level, and very monotonous. The ascent is then more rapid for the next 27 miles, when we come to the first long iron bridge—Puente de Atoyac—and from this point to Boca del Monte, 54 miles further, the scenery is the most grand and magnificent, and the engineering the most difficult, I have ever seen in any country. From the station in the village of Maltrata the train winds to and fro on the brow of the mountains, a distance of 8¼ miles, when it is almost perpendicularly above the station, and at a height of 1513 feet. The snow-covered peaks of Orizaba, Malinche, Popocatepetl and Iztaccihuatl—all of them between 17,000 and 18,000 feet above the level of the sea, and all four of them in view for several hours after we leave Boca del Monte—are the grandest objects in their line to be found in the world. The highest grade on this road is 290 feet to the mile, and the shortest curve only 250 feet radius. All of the bridges are of iron, and the curved bridge of Metlac has a radius of only 350 feet. The engines, of English manufacture, weigh seventy tons, and cost $30,000 each. They are double-enders, and made of steel throughout, their bearings having been invented for this road, to enable them to follow the very short curves. They are capable of taking the train up a grade of 400 feet to the mile.

The expenses of the different trips I have described are as follows: New York to Havana, by steamer, first class, $65 currency; second class, $40 currency; New York to Vera Cruz, first class, $100 gold; second class, $60 gold; New York to New Orleans, first class, $130 gold; New Orleans to Vera Cruz, first class, $60 gold; second class, $45 gold; New Orleans to Havana, first class, $90 gold. All information respecting days of sailing, state-rooms, etc., may be obtained from F. Alexandre & Sons, 31 and 33 Broadway, N. Y., and J. M. Witherspoon, 35 Carondelet street, New Orleans. The railroad fare from Vera Cruz to Mexico is $16, $12 and $8 gold, for the first, second and third classes. Up to the present time there are no sleeping or parlor cars on this route. The expense by land from New York to New Orleans, by either of the four routes before mentioned, is but $42.50.

The expense of living in this city is reasonable. At this hotel, which stands in the front rank, it amounts to $4 or $5 per day (according to the room occupied) to transient guests, but rather within $100 per month to those who remain a long time. In Vera Cruz, Orizaba, Cuernavaca, and other cities I shall recommend to patients, it is $2 per day, and less by the month. The charges for medical attendance will be specified in my next letter.

The annoyance mentioned by books of travel in Mexico from insects of divers kinds—mosquitos, fleas and other "camarades de lit," and even scorpions, perhaps—I have scarcely experienced at all. I was invaded by a horde of mosquitos with a very high note, during a night at Vera Cruz; and I have here seen a single diminutive, and very harmless-looking individual of the "cimex" family; but the latter did not make, and I presume had not meditated, any attack upon me. The so generally asserted danger to the tourist from robbers is also doubtless an exaggeration; a persistent repetition, perhaps I should say, of what was true fifteen or twenty years ago. Not a single traveller upon the railroad has been thus molested since it was first opened, four years ago. I should, however, add that there is always an escort of fifty to one hundred soldiers on board of each passenger train. It is also currently reported that the rich bankers, Barron and Escandron, do not live in their splendid country seats at Tacubaya, four miles out of this city, lest they should be kidnapped, and be compelled to pay an immense sum for their ransom.

I had heard of the present revolution just before leaving home, and find it is daily gaining ground. The *pronunciamientados* yesterday threatened to destroy the bridges on the railroad and blow up the tunnels, unless the government at once sends them the sum of $25,000. The fulfilment of this threat would bring me a real inconvenience. *Mais nous verrons.*

It is calculated that but one in one thousand of the inhabitants of this city, or two hundred and fifty perhaps in all, speak the English language. French is much more in use here; but he who has a sufficient acquaintance with the Spanish language has very great advantages. English is spoken at the Hotel Gillow, which is therefore well patronized by Americans. It is also spoken by one of the clerks of the Iturbide.

I have been thus explicit on non-medical points in this communication, hoping that I may induce some of my professional brethren also, as well as their patients, to take this delightful trip. It will be seen that it can be accomplished by an absence from New York of scarcely more than four weeks. My next shall be of a more strictly professional character.

E. R. Peaslee.

SHORTENING THE COURSE OF MEDICAL STUDY,

AND THE REQUIREMENTS OF THE UNIVERSITY OF VIRGINIA.

U. S. N. Hospital, Washington, D. C., April 8, 1876.

To the Editor of The Medical Record:

Dear Sir:—The spirited and forcible manner with which your valuable journal has directed attention to the existence of great abuses in the matter of awarding diplomas at Louisville, and other medical colleges, merits the commendation of a profession which is being prostituted. These schools deem thoroughness of knowledge to be unessential, and by their *forcing* process produce a mushroom growth in our medical field, that can live only in the soil of charlatanism and imposture. In the Record of April 1st., you quote from the editor of the *American Medical Weekly* (Dr. Gaillard), to the effect that any one can spend five months—the usual winter course of study—at any college, and at the expiration of the term, in

March, can enter the Long Island, or Cincinnati colleges, or the University of Virginia, and graduate in medicine in the following June—after only nine months' instruction! You seem to place confidence in this affirmation, and, in so far as it relates to the colleges at the first two named places, it may be true. But Dr. Gaillard does not appreciate, or give credit for the vast difference between the requirements for graduation at the University of Virginia, and at the other places, and between their courses and modes of instruction. I do not believe you would wittingly aim a blow at the University of Virginia, through her medical department,—and yet you seem to do so in commenting on Dr. Gaillard's statements, when you declare that there is no reason to doubt their accuracy! His statement savors of truth, but leads to error. It is true, that an intelligent man *can* graduate in nine months at the University of Virginia, but it requires excessive labor, and few accomplish it. Graduation there does not depend at all on the time one has studied,—whether that be six months, a year, or six years – but depends on merit, as developed by the ordeal of rigid written examinations. The term there is nine months long, and there is no such thing as a "Summer Term." The University makes no boast of clinical advantages; but she does drill her students, and prepares them with conscientious thoroughness to appreciate and understand morbid states and therapeutic indications. The untutored, unprofessional mind is incapable of appreciating intelligently "Clinics," nor are they a *sine qua non* of success. There, under the guidance of talented professors, a firm foundation of medical knowledge is laid, in each of the chief branches of medicine, during nine months, uninterrupted by Saturday or Christmas holidays. A man does not *then* secure his diploma after an examination of fifteen minutes duration on a branch, as he may in most of his sister city colleges, but each branch is honored by *a day*, and the result is shown in a graduation of about twenty-five per cent. of the applicants. What other college, anywhere, shows such a record? The noble old institution needs no laudation; and, when graded with institutions that sell permits to practice, she can proudly refer to her history, and charge ignorance, or malice, against her maligners! This communication, in vindication of the University of Virginia is evoked by the statement referred to. It is necessarily imperfect from brevity, but is written in all candor, under a sense of injustice by imputation, if not by affirmation, done an institution, the peer, at least, of any college in this country. Do not, therefore, speak of her course in graduating students as a "monstrous evil." Do not speak of her as a "so-called high place," in which "corruption" is going on; and level her with mercenary institutions at Louisville and elsewhere. Comparisons are odious to her! Pardon me for occupying so much of your space.

Very respectfully,

WM. R. DUBOSE,
Asst. Surg'n U. S. N.

DEATH CERTIFICATE FROM UNQUALIFIED PERSONS.

TO THE EDITOR OF THE MEDICAL RECORD:

SIR.—Perhaps you will consider the following questions of sufficient general interest to publish answers to them: When an attack of illness proves fatal in the case of a patient attended medically—till death by a person, (a druggist possessing no proper qualifications,) who has not a "Diploma," nor a "License;" can an undertaker remove the body for interment, without any infraction of the law of the State of New York, before a coroner's inquest has been held on the body? Can a person, unqualified for the practice of medicine, as above indicated, legally give a "Burial Certificate," over his own signature, to which is attached the title-initials "M.D." for the purpose of obtaining a permit, to allow the body to be conveyed for interment within the precincts of the city of New York? If to do so be an infraction of the law of this state, what, (if any,) is the penalty? W. M. D.

"SUBURB," MARCH 30TH, 1876.

[It is very clear from the foregoing statement, that the person who presumed to grant the certificate in question, had no possible right so to do, and is guilty of a misdemeanor which is punishable "by imprisonment, in the county prison, not exceeding one year, or by a fine not exceeding five hundred dollars, or by both fine and imprisonment."—ED.]

PERI-NEPHRITIC ABSCESS IN CHILDREN.

TO THE EDITOR OF THE MEDICAL RECORD:

SIR.—In the March 25th number of THE RECORD I see a notice of a paper read by Dr. V. P. Gibney before the "Medical Journal Association," on the above subject, in which he reported seven cases, the ages being respectively 8, 1½, 6, 9, 3½, 2½, 6, 10 and 2 years. He states that this affection had been denied by some authors, and that only three cases had heretofore been placed on record. Such being the case, it may be interesting to add one to the number, especially as it is probably the youngest one reported. The child, a patient of Dr. Isaac E. Taylor's, came under my care last summer, at Saratoga Springs, whither it had been sent by him on account of an obstinate affection of the stomach and bowels. It was then about five weeks old. The mother could not nurse it, and was trying to bring it up by hand. After trying various articles of food and various remedies with only partial success, a wet-nurse was procured, and the symptoms began to amend very soon. Previous to this, the child had had irregular fever; the temperature ranging from 100 to 104, rarely as high as the latter figure. It was in a good deal of pain at times, requiring anodynes; at other times quite free from pain, and looking cheerful, especially when out of doors. Sometimes congestion of the brain seemed to threaten, and the pupils were quite contracted when not under the influence of paregoric. Belladonna was then given with good effect. At one time, while I was absent, Dr. Marion Sims called in to see the patient, and subsequently saw it several times with me. One day, soon after we had left the child, the nurse called me back to say that she had discovered a "swelling" in the side. On examination, there was a tumefaction in the left side, below the cartilages of the ribs, in the lumbar region, both to be seen and felt; it was as large as a small orange, and fluctuated, being very elastic. A poultice was directed; and the next day it had increased in size, and fluctuated more distinctly. With Dr. Sims' approval, I concluded to puncture it; and Dr. Grant, of Saratoga, being called in, brought an aspirator, and aspiration was attempted, but failed. I therefore made an incision with a bistoury, and gave exit to about three ounces of healthy pus. A tent was placed in the wound, to maintain its patency. The next day the matter was running freely, and the child much better. Not to prolong the case, I will merely state that it was difficult to maintain the opening, and that it was enlarged once; and that when it did not give free vent to the fluid, the child was

invariably restless and feverish. Quinine, which had controlled the fever pretty well before the appearanc of the swelling. was continued for some time. The child continned in a very doubtful condition up to the time of its departnre for home; but by that time, some two weeks after the operation, the discharge had gradually diminished, until it scarcely amounted to a spoonful in 24 hours. But the tumor could still be felt, although smaller and not fluctuating. In November following, two months after it passed from under my care to that of Dr. Taylor, I saw the infant, and it was as fine and healthy a child as could be, and there was no appearance of the disease.

The very sudden appearance of the tumor in this case was remarkable. The child was stripped and washed daily, and the mother and nurse both watching it with great solicitude, and yet neither of them noticed any swelling until it assumed the proportions above described. The day after the puncture I made out the outlines of the tumor with great ease, and had no difficulty in diagnosing nephritic abscess.

Dr. Gibney is reported as regarding the "diagnosis of peri-nephritic abscess in the very young child as impossible." I presume he means before the appearance of any tumor.

PALATKA, FLA. FREDERICK D. LENTE, M.D.

PROFESSIONAL RESPONSIBILITY IN PRODUCING ABORTION.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—A man was arrested on a charge of attempting criminal abortion by the administration of aloes in whiskey. The attorney for the prosecution showed me some aloes which he had received from the woman. My opinion of its properties as an abortifacient was asked; I told the attorney that, under favorable circumstances, it was regarded as one of the principal drugs employed for that purpose, and more likely to be employed than any other, not excepting ergot. I related to him the following circumstance. Some four years ago, a married man applied to me for medicine to *make his wife's turns come regularly*, as he said, stating that it had been over three months since she had menstruated. I asked him positively if she was not pregnant; he replied that she was not. I prepared a compound, the basis of which was aloes; in the course of eight or ten days I was sent for in great haste to see her. When I arrived, I was shown a "something which had passed from her," as her husband said. I ruptured the sac and discovered a fœtus at least three months old; he asked if I thought the medicine did it; I replied not, but at the same time I believe that this fellow designedly misrepresented the condition when he got the medicine from me.

Now, in consequence of these expressions of mine to the attorney, it became generally known that I said aloes would produce abortion. This view seemed to prejudice the public against the defendant, and certain *interested* parties, upon the authority of *still more interested physicians*, endeavored to produce the impression that aloes would not produce abortion, and had never been known to do so. I desire to have an expression of your opinion as to the properties of aloes and other abortifacient drugs. New York is not the only town where abortionists flourish. Perhaps some of your readers can give their experience, or, rather, their observation.

Very respectfully,

C.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department United States Army, from April 9th to April 15th, 1876.

BY S. O. 71, A. G. O., April 8, 1876, the following changes are made:—

HAPPERSETT, J. C. G., Assistant Surgeon.—Relieved from duty in Department of the Missouri; ordered to Philadelphia, and report thence by letter to the Surgeon-General.

HUBBARD, V. B., Assistant Surgeon.—Ordered to Department of California for assignment to duty.

REED, W., Assistant Surgeon.—To accompany recruits to Department of California, and upon completion of this duty, ordered to Department of Arizona, for assignment to duty.

The following named officers are relieved from duty in the Military Division of the Atlantic, and ordered to the Department of Texas, for assignment to duty:—

GODDARD, C. E,, Surgeon.

COMEGYS, E. T., Assistant Surgeon.

SHANNON, Wm. C., Assistant Surgeon.

The following named officers are relieved from duty in the Division or Department where they are now serving: ordered before the Army Medical Board, in session in New York City, for examination for promotion, and upon its completion, to the Division or Department set opposite their names, for assignment to duty:—

MEACHAM F., Assistant Surgeon.—From Military Division of the Atlantic to Department of Texas.

STYER, Chas., Assistant Surgeon.—From Department of the South to Military Division of the Atlantic.

CORSON, J. K., Assistant Surgeon.—From Department of the South to Military Division of the Atlantic.

WEISEL, D., Assistant Surgeon.—From Department of the South to that of Texas.

KIMBALL, J. P., Assistant Surgeon.—From Department of Dakota to Military Division of the Atlantic.

EWEN, C., Assistant Surgeon.—From Department of the Gulf to Military Division of the Atlantic.

And the following, upon completion of their examination, to report by letter to the Surgeon-General:—

HORTON, S. M., Assistant Surgeon.—From Department of Texas.

JAQUETT, G. P., Assistant Surgeon.—From Department of the Platte.

WHITEHEAD, W. E., Assistant Surgeon.—From Department of Texas.

BUCHANAN, W. F., Assistant Surgeon.—From Department of Texas.

MCELDERRY, H., Assistant Surgeon.—From Department of the Colombia.

BENTLEY, E., Assistant Surgeon.—From Department of California.

GIRARD, J. B., Assistant Surgeon.—From Department of Arizona.

KING, J. H. T., Assistant Surgeon.—From Military Division of the Atlantic.

CAMPBELL, A. B., Assistant Surgeon.—Granted leave of absence for one month, on Surgeon's Certificate of Disability. S. O. 62, Department of Texas, April 8, 1876.

HALL, J. D., Assistant Surgeon.—Granted leave of absence for two months. S. O. 63, Military Division of the Atlantic, April 11, 1876.

HAMILTON, J. B., Assistant Surgeon.—Resignation accepted by the President, to take effect May 31, 1876. S. O. 71, A. G. O., April 8, 1876.

Medical Items and News.

CONTAGIOUS DISEASES.—Comparative statement of cases of Contagious Disease reported to the Sanitary Bureau, Health Department, for the two weeks ending April 15th, 1876. WALTER DE F. DAY,
Sanitary Superintendent.

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro Spinal Meningitis.	Measles.	Diphtheria.	Small-pox.
April 8th.....	0	7	91	4	59	100	40
April 15th.....	0	8	103	5	72	75	29

Dr. ALFRED L. HASKINS, a promising physician of Boston, was killed April 3, by a fall through the hall well of the Huntingdon House, at which place he went to see a patient.

THE BELFRY MURDER CASE.—Dr. E. Cotting contributes, in the Boston Medical and Surgical Journal, a very interesting medico-legal account of the Belfry Murder Case.

VENTILATION OF TOMBS PRISON.—Measures are being taken to ventilate the prisoners' quarters in the Tombs Prison.

THE ARMY MEDICAL STAFF BILL has passed the Senate, and its provisions are adopted by the Military Committee of the House.

THE SEWERAGE OF BOSTON is in a bad way. The necessary improvement will require so much money that public meetings are to be called to consider the subject.

SIR JOHN CORDY BURROWS, F.R.C.S. Eng., of Brighton, President-elect of the British Medical Association, died March 25, 1876, in the sixty-third year of his age.

NOXIOUS GASES FROM MANUFACTORIES.—A Royal Commission has been appointed by the British Parliament to inquire into the working and management of works and manufactories giving off noxious vapors and gases, and their effects on animal and vegetable life.

ANOTHER CASE OF MILK POISONING.—*The British Medical Journal* (April 1, 1876) says that cases of milk poisoning have occurred at Greenock, and that in twenty cases of enteric fever the disease was directly traced to contaminated milk.

INCREASE OF INSANITY IN IRELAND.—In their last annual report, the Lunacy Commissioners advert to the increase of insanity in Ireland. Between the three kingdoms, they observe, the authenticated number of mentally affected may now be set down as fully 90,000, or 18,000 more than in 1860. The commissioners, in view of these facts, strongly recommend the systematic study of insanity in the regular medical schools.

A DEATH FROM ETHER-DRINKING is reported from Draperstown, County Londonderry, Ireland.

A DEATH FROM CHLOROFORM during a dental operation is reported from Liverpool. The immediate cause was "arrest of the heart's action." The jury absolved the dentist from all blame. Commenting on this case the *British Medical Journal* says:—"Nitrous oxide gas has proved itself so efficient and so safe an anæsthetic agent for dental purposes, that the employment of a dangerous agent, such as chloroform, can rarely be justifiable; and if evidence to the effect were tendered, as it well might be, the jury might be expected to add to their verdict a rider which would be unpleasantly severe. The dentist who administers chloroform where nitrous oxide can be made to serve, incurs a very solemn responsibility."

A CONGRESS OF SCANDINAVIAN DOCTORS will be held in Gothenburg during next July. Articles intended for exhibition will be admitted duty free, if afterwards removed.

NEW STATUES IN THE COLLEGE OF PHYSICIANS IN LONDON.—Three statues have lately been placed in vacant niches in the entrance to the College of Physicians. Immediately over the doorway is that of Linacre, the projector and first President of the College, on one side that of Harvey, and on the other that of Thomas Sydenham.

H. CARRINGTON BOLTON AND THE "PAPYRUS EBERS."—Mr. Charles Rice, the author of the article on "*The Materia Medica of the Egyptians*," in our last number, informs us that the author of the account of the "Papyrus Ebers" in the *Tribune* was H. Carrington Bolton, Ph.D., of Columbia College, N. Y., instead of the late Librarian of the Astor Library, as stated.

THE DISCOVERY OF ANÆSTHESIA.—"In Mount Auburn cemetery, near Boston, there stands to-day a monument erected by loving hands to the memory of Dr. Morton. On the four faces of it there are inscribed, in order, the legends: "Inventor and revealer of anæsthetic inhalation. Before whom, in all time, surgery was agony. By whom pain in surgery was averted and annulled. Since whom science has controlled pain." In the light of the above record, which I believe I have stated with accuracy, and I know without prejudice or favor, I simply ask, are these inscriptions true? Modify the first so that it shall read, "Inventor and revealer of the anæsthetic inhalation of sulphuric ether," and not the most rigid constructionist can take exception to the statement, for such honor is assuredly due him, and will remain to the end of time. But can we even then reconcile the remaining legends with the impartial record of history? I fear not, and I believe, rather, that when the story of anæsthesia shall have been fully and finally written up, this verdict will be rendered in favor of the obscure dentist, whose memory has been neglected and whose name has been almost forgotten—*Dr. Horace Wells*, of Hartford, Connecticut."—Prof. E. S. DUNSTER, M.D., Ann Harbor, Michigan.

EFFECTS OF VEGETATION UPON HEALTH.—It is interesting to know that the sunflower, which will grow almost anywhere, and could be turned to various useful purposes, is one of the most valuable of sanitary agents, since not only is it ozoniparous, but also destroys deleterious miasmata. It should be noted, as a further proof of the good influence of plant culture on health, that while the manufacture of ozone is an independent work, carried on by the flowers alone, the green leaves are performing their sanitary function by extracting carbonic acid gas from the atmosphere, and helping to preserve that proportion in its elements which makes it healthful. More remarkable, perhaps, than all is the eucalyptus, of which we have recently

heard so much, and of which we shall soon know more. Thus the cultivation of flowers is a work not merely delightful and humanizing in itself, but one which, in a way most beautiful and picturesque, confers a positive benefit on society, so great that it can hardly be overrated, especially in large towns, where there must necessarily be so much to poison and deteriorate the air we breathe. It may be added that the sunflower thrives even in the heart of London, and that it is readily propagated from seeds sown in March or April. It is nearly allied to the common Jerusalem artichoke, which also grows in the smokiest of districts.—*Gardener's Magazine.*

Ophthalmic and Aural Institute, New York.—During the year 1875, 4,530 new patients were treated in the dispensary, namely, 3,662 for diseases of the eye, 758 for diseases of the ear, and 110 for diseases which were not classified. Three hundred and thirty-eight patients were treated in the hospital department. Of these, 98 paid the entire expense of their accommodation, amounting to from three to five dollars per diem; and, in addition, made such compensation for surgical and medical attendance as is customary in private practice. The aggregate number of days during which these patients were supported in the Institution was 1,126. One hundred and ninety-four patients, receiving an aggregate maintenance of 5,965 days, paid only in part for their accommodation; and 46 patients, receiving an aggregate maintenance of 1,006 days, were treated wholly without charge. The aggregate maintenance of all patients covered 8,097 days, and the average daily number of inmates in the Institute was 22⅛. The number of surgical operations—excluding those of minor importance—performed during the year was 420, of which 386 were for diseases of the eye, and 34 for diseases of the ear. The operations on the eye included 51 operations for primary cataract, 71 operations on the iris, 102 operations for strabismus.

From the time when the Institution was opened, in May, 1869, to the 31st of December, 1875, 23,482 patients have been gratuitously treated in the dispensary, and 1879 admitted to the house. During that time 2,701 operations have been performed. As heretofore, opportunities for theoretical and practical instruction both in ophthalmology and otology have been afforded to medical students and practitioners, and the patients of the dispensary and hospital departments have furnished ample illustration of the various diseases of the eye and ear. Systematic lectures and practical courses have at different times been given on the physical exploration of the eye. The following gentlemen compose the medical staff: Dr. H. Knapp, Surgeon; Dr. Thos. R. Pooley, Dr. Emil Gruening, Dr. Rudolph Gebser, Assistant Surgeons; Dr. Adolph Alt, Resident Assistant-Surgeon; Dr. W. F. Fluhrer, Clinical Assistant.

Dawson's *vs.* Piffard's Battery.—The accuracy of our report concerning the trial of Cautery batteries at the Journal Association having been called in question by Dr. Dawson, in a letter in the last Medical Record, we have personally investigated the two principal points which he raises, viz.: as to the relative size of plates used by him and Piffard, and the amount of fluid employed by each. We find that in both respects our report was correct, and consequently that Dr. Dawson was mistaken. Dr. Piffard's plates used on that occasion measured 5½+ inches and not 6½+5½, as stated by Dr. Dawson. Upon other matters, relating to the merits of their batteries, we suspend judgment until after the report of the committee appointed by the Journal Association to investigate the questions raised.

Quarantine Self-Supporting.—There appears to be a reasonable probability that the Legislature will do away with the present system of quarantine fees, and bestow upon the Health Officer a fixed salary. A bill having such an object in view, has been introduced into the Senate. It provides that hereafter all fees accruing to the Health Officer shall be paid to the Treasurer of the Board of Quarantine Commissioners, and be by him disbursed at the order of the Board, to the care and maintenance of the entire Quarantine establishment of the port. The Health Officer shall be appointed, as now provided, and receive $8,000 per year, and he may appoint his first and second assistant physicians, subject to the approval of the Quarantine Commissioners. The First Assistant shall be paid $6,000 per annum, and the Second Assistant $4,000. The Commissioners shall appoint, on requisition of the Health Officer, as many other assistant physicians, superintendents, and other employés as may be necessary. The Commissioners shall fix the salary of these appointees, and pay all the expenses of the establishment, but there shall be no appropriation made by the State for the care and maintenance of Quarantine, except for the salaries, clerk hire, and office expenses of the Commissioners of Quarantine. The Governor and Controller may from time to time reduce the revenues of Quarantine upon the recommendation of the Health Officer and the President of the Board. The Commissioners are required to make quarterly reports to the State Controller of receipts and expenditures, and to report annually the condition of the establishment to the Legislature. It shall not be lawful to use the boats or other appurtenances for pecuniary benefit to any official or employé. The Commission shall, with the consent of the Health Officer, select, licence, or dismiss all persons required to be licensed under Quarantine, and fix the charges for licenses. Additional regulations are provided for the management of the establishment. The Commissioners of Quarantine shall have power, subject to the approval of the Health Officer and Commissioners of the Land Office, to sell all property unnecessary for use. When such sales are made, a detailed statement of the same shall be rendered to the Controller of the State, and the proceeds immediately paid into the Treasury of the State of the property belonging to the State, otherwise the proceeds shall be devoted to the care and maintenance of Quarantine.

Medical Night Service in Paris.—From January 1, when this system was inaugurated, to March 1, 630 visits have been made by the physicians who offered their services to the prefectory of police.

Dr. Vleminckx, the President of the Belgian Academy, and the originator of the Vleminckx's Solution, which came into such extensive use on the Continent in the treatment of scabies, has just died at Brussels, aged 76.

LEUCOCYTHÆMIA.

BEING A PAPER READ BEFORE THE MEDICAL SOCIETY OF THE COUNTY OF NEW YORK, MARCH 27, 1876.

By EDWARD G. JANEWAY, M.D.,

PHYSICIAN TO BELLEVUE HOSPITAL, N. Y.

PART I.

THE subject to which the paper is devoted this evening is perhaps a little old and trite; and yet I feel that the members of the Society will pardon me for opening the discussion on this subject; especially so, as, of the three cases whose histories I will first read, and which have come under my care during the past two years, no previous diagnosis had been made, though they had presented themselves to those undoubtedly well acquainted with the literature of the subject. This circumstance has made me feel that some might entertain the idea that leucocythæmia was an infrequent disease, and hence be deterred from making that easy microscopic examination which would settle the diagnosis in any doubtful case.

In writing this paper, my endeavor has rather been to present some interesting facts about this disease—to give such statements as I could vouch for, as the result of the study of those histories which I had time to examine—than to offer a complete article on the subject. I rejected all cases occurring before the microscope was used, as they offered nothing additional to those observed since. Neither have I accepted all recorded since, some seeming to me a little doubtful. Such are many of the cases called by Prof. Bennett slight leucocythæmia. If I had been willing to accept such cases as illustrations of this disease, I might have added largely to the number which I could report as coming under observation with this complaint. They belong rather to the class of leucocytoses, due to some other disease.

The first case of this disease coming under my observation during the last two years was the following, brought to me by Mr. (now Dr.) Gordon. I presented the patient, and exhibited a drop of his blood under the microscope, to the members of this Society some time since.

C. P.; male; age, 32 years; married.

He had no occupation until he was 21 years of age. After this he was in the army for three years. Then for five years he was employed in a steel factory. There he was necessarily exposed to an extreme degree of heat for periods of twenty minutes' duration, and as soon as possible afterwards he would go into the open air. For the greater part of the three next years he was engaged in driving. The only taint in his family is due to the death of his mother from phthisis pulmonalis, after a two years' illness, at 35 years of age. His habits were regular. He, however, for a period of two years, some six years before I saw him, was in the habit of imbibing a good deal of ale.

The diseases from which he had suffered were swamp fever of several weeks' duration, twelve years before I saw him, and gonorrhœa and gleet, lasting nine months, three years later. The patient's present illness first manifested itself about three years before his first visit to me. At that time he had suffered from a pain in the left hypochondriac region, associated with shortness of breath. The physicians treated the disease as pleuritic, using blisters. The pain disappeared after lasting for a month.

Shortly after this time his legs became swollen, and an eruption appeared on them, due, according to his account, to heat. The disease was probably of an eczematous nature, as it was attended by a slight serous discharge.

About this same time, he noticed a lump under the free border of the ribs on the left side. As this lump increased in size he grew weaker. A cough would occur after eating and bring on vomiting. For some time he was troubled with constipation of the bowels. The appetite was unimpaired. His urine throughout was free and of large quantity. He had been subject for about four months to almost daily attacks of epistaxis; and for some time to dyspnœa on exertion, occurring to a less extent, even when quiet. This he stated was rather a sort of desire for breath than actual distress. Pallor had existed for one year. His strength had gradually decreased and the venereal appetite became weakened. He stated that he urinated seven or eight times a day, and was especially troubled by the desire when shaken up, as in riding in a car.

I saw him first in February, 1874. His stature was 5 feet 6 inches, weight 139 pounds—the same as when in good health. He was pale, though by no means remarkably so.

The abdomen was very much enlarged, and protruded more on the left than on the right side. The superficial veins were quite apparent.

Measurement of abdomen at umbilicus,	36	inches.
" " " " eighth rib,	34	"
" " chest at sixth rib,	32	"

Expansion of chest from 31½ to 33½ inches.

The apex beat of the heart was perceptible in the fourth interspace on the left side under the nipple. There were no physical evidences of disease of the heart or of the lungs.

Percussion of the abdomen showed dulness, which commenced above in the infra-axillary space at the seventh rib, left side, and descended so that the anterior border of the dull region corresponded to a point four inches to the right of the umbilicus, and then descended almost vertically into the pelvis.

The posterior limit of the dull region corresponded to a vertical line drawn through the anterior superior spinous process of the ilium. Back of this line tympanitic percussion note was present.

Palpation showed the region mapped out by percussion to be occupied by a flat, smooth tumor, firm to the feel, painless, and presenting two indentations on its anterior border. The tumor moved with respiration, and to a slight extent with movements of the body. A soft blowing murmur could be heard in the epigastric region when the patient lay on his back.

A microscopic examination of the blood showed a diminution in the number of the red globules, and as marked increase in that of the white. The latter bore the proportion to the former of about 1 to 4.

The colorless globules were round, granular or else undergoing amœboid movement. Their size varied from $\frac{1}{2500}$ to $\frac{1}{1500}$ of an inch. The majority were about $\frac{1}{2000}$. On the addition of acetic acid they showed from one to four nuclei. Those, with two or three, were the more numerous. There was no doubt that the tumor was an enlarged spleen. I advised Dr. Gordon to try cod liver oil, iron, phosphorus, ergot, quinine, and the drinking of fresh blood. These measures, tried at different times, were of no avail; save perhaps, that his health remained in about the same state until a short time ago

He has, while under observation, suffered from epistaxis, exhausting sweats lately, hemorrhoids, a distressing tension of the abdominal wall, and the same inconvenience as formerly mentioned, due to the pressure of the enlarged spleen on the bladder. He had when examined no retinitis nor any anæmic bruit.

The next patient was Bridget Ford, age 33 years; married.

There was no evidence of any hereditary tendency to disease. She first menstruated at fifteen years of age, was married at eighteen, and had eight living children born to her, of whom four are now dead.

For two years before her visit she had been troubled with pain in the left hypochondriac region, coming and going several times a day. For this pain she had been to physicians, some of whom had treated her for renal disease. For these two years her strength had been failing, and she had been growing paler. Three months before she had a miscarriage of a six months' fœtus, putrid when removed. A good deal of flooding attended the miscarriage. For seven months she had been troubled with varicose veins in the legs, and some five months before the veins in both legs gave way, owing to which she lost a large quantity of blood. Since the miscarriage she had complained of shortness of breath.

Three months before I saw her, she first noticed a lump in the left side, which had increased a good deal during this time. She had no impairment of her special senses, nor of her mental faculties. Her appetite was poor, but she had neither dyspepsia nor vomiting. Her bowels had a tendency to constipation. She had menstruated about three weeks before her visit, but noticed nothing about it except that it lasted two weeks.

December 23d, 1874. The patient was a thin, pale-faced woman, with a sallow complexion, possessing a slight tinge of yellow. Respirations 18 per minute; pulse 72 (sitting); temperature 99½° F. *Physical examination:* The lungs were normal; the heart was pushed slightly upwards; no murmur attended its action.

The abdomen: A large tumor occupied the left hypochondriac region, and extended from that point downwards, and to the right, so that its anterior border was on a line with the umbilicus, and its lower end descended a little below a line drawn from one anterior superior spinous process of the ilium to the other. Above it reached the sixth rib, and posteriorly, the anterior border of the quadratus lumborum muscle.

Measurement of the abdomen at umbilicus, 32¼ inches; at eighth rib, 32 inches. The tumor measured twelve inches in length, and ten in breadth.

The tumor was smooth, except that its anterior border presented two indentations, one of these situated at the umbilicus being quite deep.

The posterior border was rather more rounded than the anterior.

It felt rather firm, and could be grasped between the hands; and anteriorly, owing to the laxity of the abdominal wall, the hand could be passed under it. It was tolerably moveable, and changed its position somewhat on changes of the position of the body. Tenderness existed only at the margin of the ribs. The splenic dulness extended posteriorly only as high as the tenth rib, and on full inspiration could be depressed to the twelfth. The liver was perhaps a little enlarged.

Microscopic examination of the blood: There was a marked increase of the white globules. Twenty to twenty-five could be counted in the field of an ocular 3, Objective 10 (immersion), Hartnack. They varied in size from $\frac{1}{2500}$ to $\frac{1}{1000}$ of an inch. They were round, granular under high powers, and developed from one to five nuclei by the use of acetic acid.

They appeared to bear a relation to the red of 1 to 3, 1 to 5 under low powers, but by the use of the high powers, the proportion did not seem quite so great.

Patrick Gagarty; aged 47 years; married; a house painter by occupation. He has been a painter for twenty-one years. He has never had venereal disease, and was of regular habits, save venereal excess with his wife. He had had ten children, four of them still living. He had intermittent fever eighteen years ago, lasting ten months. He had no other illness until four years ago; then had small-pox, which produced enlarged glands under his jaw, on either side. He has never had lead colic nor any symptom of lead poisoning.

Two years ago he states that he was as healthy as ever. Then he had short breath and severe cough at the outset. The cough has continued. The pallor was noticed by his friends about three and a half months ago.

At the time of his admission to Bellevue Hospital he was very pale, and had two enlarged glands, one under either angle of the lower jaw, the right being rather the larger. The axillary glands were not enlarged, and the cervical only trifingly so at the lower part. The inguinal glands were a little enlarged; a careful examination of the abdomen failed to detect any glandular enlargement, if it existed. The lungs showed evidences of bronchitis, and of some œdema.

There was a plain basic systolic murmur affecting the heart, and one readily audible over the aorta, etc., of the cardiac systolic rhythm.

The spleen was five inches in vertical and six in transverse measurement, though probably still longer, owing to the upper and lower extremities being somewhat bent. The liver was slightly enlarged. Since admission he has had epistaxis, and some œdema of the legs, a moderate ascites, a febrile movement of slight intensity, and for a few days a severe diarrhœa. The number of his red globules is from two to three times as great as that of the white. The fibrin forms as usual. The white globules are, for the most part, of the small variety, many of them being only two-thirds of the size of the red. There are a number of the larger size, and these show the ordinary nuclei. The small variety either appear as apparently naked nuclei or non-nucleolated cells; or else as nuclei, with a very closely surrounding protoplasm.

A drop of the blood when he first entered the hospital looked like water containing a little reddish sediment. It had a faintly alkaline reaction.

These three cases are still living. The first has lately been growing weaker, and is developing a more marked cachexia. The second has improved without taking any special treatment. She became offended with me, owing to the prognosis which I gave her; and she has lately had no medical attendance, but follows her occupation of fruit peddler in the open air. I tried the other day to persuade her to allow me to re-examine the condition of the blood, but in vain.

The condition of the third is critical, though presenting a trifling improvement. In his case I used hypodermic injections of ergot, but without benefit. After a little an abscess was formed, and this medication had to be discontinued. The use of phosphorus produced diarrhœa, which came near carrying the poor fellow off. At present he is on nutritious diet quinine, iron, and stimulants.

The disease under consideration had an unhappy in

troduction to the profession, inasmuch as it led to a persistent quarrel and acrimonious dispute between Prof. J. Hughes Bennett and Prof. Virchow. Each claimed the credit for its discovery. The truth seems to me to be that Prof. Bennett, in October, 1845, published in the *Edinburgh Medical Journal* the history of a case, which he then called suppuration of the blood, with remarks. In November, 1845, Prof. Virchow published in Froriep's *Notizen*, the history of a case of white blood, with some remarks. He, in the same paper, alluded to a case observed by Lautner, called general pyæmia, and of which he entertained doubts as to the propriety of considering it as a case of pyæmia. The case, of which the post-mortem appearances only were given, had large liver and spleen; and in the latter an infarction, also lobular pneumonia, superficial cutaneous abscesses, and a large bed-sore.

Virchow, in the microscopic examination of his own case, recognized the cause of the white blood as being due to an increase of the colorless corpuscles, and spoke of the relation between the colored and colorless corpuscles as being the inverse of the natural, the colorless being the rule, the colored the exception.

Bennett, in his paper, tried to account for the pus in the blood, and said that these cells could not be white blood globules. I have consulted Bennett's original article, and Virchow's collected writings—"*Gesammelte Abhandlungen.*" Virchow published during 1846–47 new articles on white blood, with a collection of such cases as he could gather from the older and then recent literature. He also placed at the head of his article in the first volume of his *Archives*, the title "White Blood;" and, in parenthesis, after this, the name "Leukæmia." Since then the name Leukæmia, and the name proposed by Bennett in 1851, Leucocythemia, has been used to designate the disease in question.

This statement of the case I believe to be the fair one; and the inference which I have drawn from it is that Prof. Bennett was undoubtedly the first to record a case of this disease with a thorough microscopic examination of the blood, but that he fell into error in his interpretations of the facts; that undoubtedly the credit of offering a right explanation of the facts, and placing the disease on a proper basis, belongs to Prof. Virchow; that it is impossible to decide whether the publication of Prof. Bennett's case drew Virchow's attention more closely to the subject and led to the publication, in November, of a case observed on the 1st of August; that this is probable, is true from the fact that Virchow published Lautner's case, and did not, in that article, publish Bennett's, which was much more complete, and also because I cannot find that Virchow has denied reading of Bennett's case before the publication of his own. I prefer the term Leucocythæmia, proposed by Bennett, to the term Leukæmia, because the former is the more accurate. The white cell blood is better than white blood; because, whilst the blood in this disease always has an increase in the number of white corpuscles, yet the white color of the blood may not be very marked. Craigie seems never to have started any claim for the discovery of the disease. His case is recorded in the same article with Bennett's, precedes it, and in his remarks statements are made which would give him almost as fair a right to a claim as that of Prof. Bennett.

This disease may come on in an insidious manner and present many of its marked characteristics, before the patient is aware that anything more serious than a trifling malady is the cause of his ill health. In certain cases, however, it has a more sudden and distinctly characterized outset.

In looking over a large number of cases about this point, I found 45 which might be said to have begun insidiously; 16 which had a more definite origin, and 12 of which I was in doubt as to the class in which they belonged, either from imperfection in the history, or because they were on the border line. The histories, as recorded, leave the inquirer uncertain whether, in the absence of a definite examination, or some symptom continuous from a certain date, a febrile attack or pain in the side, or hemorrhage from some source, as detailed by the patient, should be received as the first decided symptoms.

This disease is usually divided into several classes according to the site of those morbid processes which stand in a probable causative relationship to it; viz., lienal or splenic—glandular—and, more recently, medullary or myelogenic, starting from the marrow of the bones.

The usual initiatory symptoms have been either pain in the left side, pallor and debility, or else hemorrhage from some source, though the latter has probably been the first circumstance to attract the patient's attention notably; an inquiry reveals the fact that, for some time before, debility or pallor or languor had existed. It is worth while to draw attention to the pain in the left side, because two of the patients whose histories I have presented to you had this as initial symptoms, and it was supposed to be due to a pleurisy, or neuralgia, or dyspepsia, or renal disease, or pleurodynia. In this early stage it is no doubt impossible to recognize the disease in many of the cases; yet an examination of the blood by the microscope and a careful physical exploration of the spleen would, I feel assured, have revealed a certain number of the cases to the medical attendant.

This pain is sometimes a sense of fulness; again, it has a more sharp character, and is very possibly due to an inflammation of the capsule of the spleen, especially as we shall see that this is an accompaniment of the disease in some cases. Where the pain gives rise to a sense of fulness, we may suppose that it is due to the effect of the pressure on surrounding parts, or perhaps on its own capsule.

In other cases, the patient has accidentally noticed a tumor in the left side, or has found lumps more or less rapidly increasing in size, in the site of the superficial glands.

The symptoms noticeable in a patient in whom the disease has made some progress are as follows: Pallor, debility, emaciation, dyspnœa, hemorrhages, dropsies, febrile movement, perspiration, diarrhœa, occasionally vomiting, cough, loss of appetite, retinitis occasionally, palpitation, difficulty of swallowing, and, as more infrequent, small abscesses, frequent micturition, salivation and stomatitis.

Let us first notice, however, the cases of sudden origin; then take up the consideration of the condition of the blood upon which a diagnosis of the disease rests; and afterwards treat more in detail the prominent symptoms. In these cases which I have called those of sudden origin, I mean rather that there has seemed to be a definite period of which one could say "then the disease began."

One* had a severe cold on a journey, and having been previously well, six months later had severe abdominal pain, diarrhœa, and noticed a lump in the left side of the abdomen. Another† had a swelling in the submaxillary region, spreading from one side to the other, accompanied by chills and febrile movement; recovered in eight days. Then patient first noticed a

* Mohr: Virchow's *Archives*, Vol. v, p. 51.
† Vogel: Virchow's *Archives*, No. 3, p. 505.

tumor in the abdomen, which rapidly increased in size.

A man 40 years of age* had a strong mental excitement, and a little later noticed a swelling on the right side of his neck, which rapidly increased.

A man † had pain in the left hypochondriac region, intermittent, and of a shooting nature. He soon noticed some enlargement at the seat of pain.

Perhaps the most marked cases of acute origin and course are those recorded by Robert Patterson, in the *Edinburgh Medical Record*, 1870, p. 1073. The symptoms seem to have come on a little over a month before confinement, and to have caused death on the eleventh day after in one case; and in another to have begun earlier in the pregnancy; but, as far as the glandular part was concerned, to have taken a rapid increase succeeding confinement, producing death on the fourteenth day after.

The condition of the blood in this disease constitutes its most distinguishing feature. It consists in an increase of the number of the white globules, a decrease in that of the red; and, in addition, a corresponding change in its chemical composition, together with other less constant alterations of this nature.

I have already described the appearance of the blood in those cases whose clinical histories I read.

The coagulation of the fibrin took place in those cases as usual, and in the last its threads could be seen very readily, owing to the paucity of corpuscular elements.

The proportion of white to red in my cases was as follows: No. 1, 1:4, or nearly so; No. 2, 1:3 to 1:5; No. 3, 1:2 to 1:3. The proportion in other cases has been somewhat varied, as, for example: Vogel, 1:2, 1:3; Uhle, equal—at one time later, 1:3, 1:5; De Purry, 1:7, 1:12, 1:19, 1:24; Mosler, 1:18; Mosler, 1:30; Jacubosh, 1:4; J. Reenke, 1:1; Blache, 2:1; Bryant, 1+:1.

Many of the cases are reported as follows: "Great excess of white;" "great numbers;" so many on the field of a given objective and ocular of a microscope, etc.

As regards chemical analysis:

	Scherer.	Vogel.	Bennett.	Robertson.	Bennett.	Benhett.
Water	791.7	815	854		833.8	828.97
Solids	208.3	185	145.5		166.2	171.03
Organic	197.3					
Inorganic	11.084					
Iron	.0298					
Earthy phosphates	.0598					
Fibrin		4.46	6		3.2	3.83
Iron of ash		3.42				
Weight of blood globules		97.4	67.5		82.3	79.33
Organic					70.4	80.54
Inorganic					10.3	7.32
Solids of serum		82.35	72		80.7	87.87

Besides these analyses, Scherer records that he found formic, lactic and acetic acids, and hypoxanthin (8 to 10 grs. in 4 oz.)

Vivid records that he found in 1,000 parts only 37 of albumen, instead of the normal quantity (76 to 80).

Koerner (*Virch. Arch.*, vol. xxv., p. 147) found in the blood from the living subject, that lactic and formic acids, albumen, gluten, uric acid, and hypoxanthin were present. Acetic acid and leucin were not found.

Folwarczny, quoted by Mosler and Koerner: Blood from a living subject contained lactic and formic acids. Gelatin, leucin, and hypoxanthin were not present.

The same blood, *post-mortem*, showed formic acid in all specimens; lactic in most; uric acid in minimo (jugular vein); tyrosin; leucin, in aortic and capillary blood; hypoxanthin only in the blood from the splenic vein; acetic acid do.; gelatin not found.

In that type of the disease in which the disease is limited to the spleen, the majority of the white globules are large, and have the ordinary appearance. In those in which the lymphatic glands are alone diseased, the majority of the white globules are small, and resemble in appearance the lymphatic gland cells, according to the German school. [This fact is, however, denied by good observers, as Cornil, and Ranvier, and Wilks.] Some have described transition forms of white to red globules. In none of my cases were such present. Ranvier could not find them. Geo. Fuller, of London, was the first who examined a drop of blood during the lifetime of the patient, and thus established a diagnosis. Mosler wrongly gives the credit to Vogel.*

TWO CASES OF ŒSOPHAGOTOMY,

FOR THE REMOVAL OF ARTIFICIAL TEETH.

By LEROY McLEAN, M.D.,

SURGEON TO TROY HOSPITAL, N. Y.

CASE I.—TOOTH PLATE SWALLOWED DURING SLEEP—SUCCESSFUL REMOVAL BY ŒSOPHAGOTOMY.—I. C., aged 30 years, a man of temperate habits, good health, and a book-keeper by profession, while visiting friends in Greenfield, Mass., in August, 1874, during sleep swallowed a gold tooth-plate, with one false central incisor attached. The plate, which was crescent-shaped, measured, from point to point, one and one half inches, and one-half inch from outer to inner edge. On the outer edge were eight sharp and irregular projections which fitted between the teeth and held the plate in position; these, from use, had become worn, and allowed of its easy removal.

He had retired at 11 P.M., and slept until 5 A.M., when he was suddenly awakened, experiencing a sense of suffocation, and a burning pain in the throat. He sprang from bed, drank a little water, and, feeling somewhat relieved, retired again. He then, for the first time, missed the plate from his mouth; and immediately realizing his condition, called for assistance.

Physicians were summoned, who made many fruitless attempts to dislodge the foreign body, finally concluding that it had passed into the stomach. He returned to his home in this city on the 29th, the day following the accident, and was attended by his family physician, who also entertained the opinion that the plate had passed down. His condition not improving, I was called in consultation on the evening of September 1st. Found him very weak and suffering intense pain; his face was haggard, and bore an anxious expression; the neck, which was swollen and in-

flamed, could not be moved without causing pain. Since accident has been unable to swallow without much suffering; and to obviate this as much as possible, the saliva, which was secreted profusely, was allowed to trickle from the mouth. Voice faint and husky; has been unable to speak above a whisper since day after accident.

I passed a pair of large œsophageal forceps, and could easily grasp the foreign body, which was apparently at the junction of the pharynx and œsophagus, but the application of much force to dislodge it was deemed impracticable, owing to the many points of resistance which the sharp projections on it offered. An operation (œsophagotomy), was then proposed. The patient readily assented to this, and an appointment was made for ten o'clock the following morning.

Chloroform having been administered, the patient readily yielding to its influence, the neck was stretched, and an incision made on the left side, midway between the margin of the sterno cleido-mastoid muscle and the thyroid cartilage, extending to within one-half inch of the sternum. The parts containing the carotid were then separated from the trachea and held aside by retractors, as was the left lobe of the thyroid body after careful dissection. The inferior thyroid artery having been exposed and pushed aside, the œsophagus was plainly seen. A large-sized lithotomy staff was then passed through the mouth, it being more easily introduced than a stomach tube, and the œsophagus pushed well forward and to the left. This served as a guide, and held the œsophagus in position, rendering the incision into it less difficult than it would otherwise have been, owing to the spasmodic efforts at swallowing which were very frequent after the administration of the anæsthetic. The incision was made longitudinally over the staff to the side of the cricoid cartilage; a finger introduced, and the plate, which was strongly impacted, removed with some difficulty from its resting-place behind the thyroid cartilage. The wound in the œsophagus was not closed. But two small arteries, muscular branches, were tied during the operation. Morphia was administered hypodermically, and the patient put to bed in a cool room.

During the first day enemata of beef-tea were given and bits of ice allowed to dissolve in the mouth. After twenty four hours enemata were discontinued, and he was allowed to drink milk, one-third escaping from wound.

Forty-eight hours after operation, could swallow fluids readily, very little passing out through opening. Fourth day ate an oyster, swallowing it without experiencing pain. Fifth day sat up, dressed, could readily swallow soft solids,—no discharge of fluids by wound. Sixth day, which was warm and pleasant, he walked about upon the piazza and around the house.

On the 18th sixteen days after operation, he visited his friends in Greenfield, returning and resuming business on the 22d, twenty days from date of operation—wound closed.*

Nov. 3d, went to New York, and was treated by Dr. Elsberg with the hope of regaining his voice. Returned unimproved. Again in February visited New York and consulted Dr. E. and was under treatment for one month, returning with voice much stronger. From that time there has been a gradual improvement, and at this writing the voice has about reached its natural standard.

* For assistance in this operation I am indebted to Drs. Ward, Cutler, Whitson and Wentworth, of this city.

CASE II.—TOOTH-PLATE IMPACTED IN CARDIAC PORTION OF THE ŒSOPHAGUS ELEVEN MONTHS AND SEVEN DAYS, CAUSING STRICTURE.—December 5th, 1873, Mr. P., living near Saratoga, while at dinner dislodged four upper false teeth, attached to a silver plate, by striking them with his fork. They were involuntarily swallowed, passing into the œsophagus.

Vomiting followed, and the plate was frequently felt rising in his throat, only to fall back again. The plate was one and one-half inches broad by about one inch in depth from front to rear.

In the evening, about five hours after the accident, Dr. Chapin arrived from Glen's Falls, a distance of six miles.

Owing to the irritation which the foreign body had already created in the œsophagus, the patient was chloroformed and an attempt made to reach the teeth. Instruments were passed down over ten inches, but failed to give any indications of touching them.

There was occasionally vomiting, but no more rising of the teeth in the throat, leaving the inference that they might have passed into the stomach. This was strengthened by a sharp and severe pain, which the patient felt in the region of the stomach.

Most of the soreness that had been caused by the accident gradually passed away, and in a fortnight or so he was enabled to swallow liquids without difficulty, and most kinds of food with varying success.

He frequently passed weeks without any marked inconvenience. A few weeks after the accident, Mr. P. served on a jury in Saratoga county, and resumed his business, that of a gentleman farmer, frequently doing his share of the work in the field.

Oftentimes, however, he would have unusual distress in the chest, or a return of the difficulty of swallowing food. He first consulted me in June, 1874, about six months after the accident. I passed an ivory-tipped probang, and found that they were still in the œsophagus, eleven and one-half inches from front of upper jaw, while the head was thrown back.

I strongly advised an operation, œsophagotomy, if a trial at removal by the mouth failed. This he wished to delay, as he said he felt "pretty well," and suffered no essential inconvenience. He afterwards went to Albany and New York for advice. Some of the physicians he saw recommended an operation, while a majority entirely discouraged it.

Thus the case was left to him and his friends, and nothing was done till November 10th; when, having had, for some weeks previous, more trouble in swallowing than usual, I was sent for. Upon arrival I concluded to attempt the removal of the plate through the mouth. It being beyond the reach of forceps, I passed a whalebone probang with swivel hook end, beyond the obstruction, and on drawing back it caught on the plate, but no reasonable force could dislodge it. On attempting to withdraw the instrument, it was found to be so thoroughly entangled with the object that for a time doubt existed as to its removal without an operation then. However, it was finally freed and the scheme of removing the plate in that manner decided to be impracticable. This was the first and only attempt made to dislodge them. The 12th was then appointed for an operation. This was eleven months and seven days from date of accident.

The operation was performed at 11 A.M. The patient having been etherized, an incision was made upon the left side of the neck, commencing opposite the thyroid cartilage, midway between it and the sterno cleido-mastoid muscle, and reaching to the sternum.

Careful dissections were made with a director,

down to the œsophagus, which was reached without difficulty. A large lithotomy staff was then passed through the mouth and the œsophagus pushed well forward, exposing its posterior wall, thus enabling me to avoid the inferior laryngeal nerve in making my incision into it. An incision large enough to admit the index finger was made into the œsophagus as near the top of the sternum as possible. I passed my finger through the opening and down, and was able to feel a constriction, below which lay the foreign body quite out of reach. I then directed with my finger a pair of polypus forceps down upon the plate, and after many vain attempts brought it up, but without the teeth, they having become detached in the effort at removal. The forceps were again introduced and the teeth felt, but before they could be grasped they passed into the stomach, and were voided by the rectum some days after. During the operation the inferior thyroid artery and one or two small branches were cut.

The wound in the œsophagus was not closed. A wet compress was laid over the line of incision and secured by bandage.

No anodyne was required after the operation, the patient suffering but little pain. Within twenty-four hours he swallowed milk, without much trouble and little loss. Thirty-two hours after, he drank half a pint of coffee without losing a drop. From that time there was a rapid improvement in his condition, all symptoms of stricture passing away, and at this date he is enjoying good health.

The voice was not injured by the operation.

I am indebted to Dr. Chapin, of Glen's Falls, for after-treatment and for practical assistance in the operation. Also to Prof. Cheever, of Boston, for essential information obtained from his invaluable monograph upon œsophagotomy.

Progress of Medical Science.

Chloroform as an Anæsthetic in the Treatment of Fissure of the Anus.—M. Nicaise has met with two cases in which four or five inhalations of chloroform, given before performing forcible dilatation for fissure of the anus, produced complete anæsthesia, without any preceding stage of excitement. In both, the operation was rapidly performed, and the patients quickly awoke. In a third case, the anæsthesia also came on rapidly without any stage of excitement, but after the dilatation was performed the patient was found to be in a most alarming condition. The thorax was absolutely motionless, without the slightest respiratory movement, the face pale and without the least muscular contraction, and the pulse very feeble. After the use of the ordinary methods, the patient regained consciousness somewhat, but she soon fell again into the same adynamic condition. This was repeated twice: and it was only after three-quarters of an hour of constant effort that the respiratory movements were permanently re-established. M. Nicaise attributes this susceptibility to the action of chloroform to the well-marked nervous condition that accompanies intolerant fissure of the anus. This susceptibility does not seem to be present in all who are suffering from fissure of the anus, but the fact of its sometimes existing should lead to great cautiousness in the use of chloroform.

M. Guyon, on the other hand, has met with several cases of fissure of the anus, in which the stage of excitement during chloroformization was prolonged and laborious, and the amount of the drug used consequently large. None of his cases proved fatal; but still the symptoms were so serious, that he has renounced the use of chloroform when performing forcible dilatation. He modifies the operation of Maisonneuve, by performing it as rapidly as possible, without attempting to avoid tearing the tissues.—*Gazette Médicale de Paris*, March 18.

A Case of Bulbar Paralysis Successfully Treated.—A patient, aged fifty years, entered the Vienna Hospital, on April 6, 1875, giving a history of cephalalgia, and pains in the nape of the neck and in the breast, especially when speaking aloud—these symptoms having lasted a year. There were no indications of apoplexy or embolism. Eight days before admission, the phenomena of bulbar paralysis appeared. On admission, the patient could not pronounce the vowels, and the movements of the lips were abolished. The paralysis of the soft palate and pharynx was not as marked as that of the lips, and the dysphagia was not very great. The laryngoscope showed diminished tension, but not paralysis of the vocal cords. The pathological lesion was agreed to be degeneration at the point of origin of the hypoglossal nerve. The treatment consisted at first in the application of strong induced currents to the external parts corresponding to the floor of the mouth, and galvanic currents from the battery of Siemen Halske containing 20 to 25 cells, the copper pole being held over the occiput and the zinc applied externally over the pharynx or œsophagus. Later on, the tongue was faradized directly. On the third of October the patient was discharged cured.—*Allg. Med. Central-Ztg.*, No. 4., 1876.

Osteotomy in Rachitic Deformities.—M. J. Bœckel, of Strasbourg, has performed this operation nine times, always with success, and has also collected the statistics of thirty-four cases in which it was performed in England and Germany. The operations were done on patients varying between the ages of fifteen months and seven years. M. Bœckel first tries manual reduction, which succeeds if the bones are still soft; if they are too hard he endeavors to break them by the ordinary methods of osteoclasty; if this also fails, he cuts down to the periosteum and peels it off the bone, which is then divided by the chisel and hammer, the saw being never used, for fear of future complications. The wound is then dressed by Lister's method, and reduction performed when it is cicatrized. Billroth does not completely divide the bone, but only incises it deep enough to render the reduction easy. When the curvature is antero-posterior, it is necessary to excise a piece of the bone before reduction can be performed. M. Perrochaud, of Berck-sur-mer, finds that the most marked distortions can almost always be cured between the ages of two and five years; in patients from eight to fourteen years old the cure is more difficult; while in those above fourteen it is very rare. His treatment consists in sea air, sea-baths, good nourishment and phosphate of lime, forty-five grains with two spoonfuls of sea-water internally every day. He uses no apparatus, but lets the children play about freely on the sea-shore, using crutches if necessary. M. Panas, while admitting that osteotomy is sometimes abused, thinks that, if the patient has passed the age of fourteen, if its deformity is evidently incurable by any other means, and if it renders existence distressing and difficult, the operation is certainly admissible.—*Journal de Méd. et de Chir.*, March, 1876.

Resection of the Large Joints and Lister's Dressing.—M. Verneuil recently communicated to the Société de Chirurgie, in the name of M. Saxtoph, of Copenhagen, the histories of four resections of the shoulders, four resections of the hip, two of the knee, two of the carpus, and one of the elbow, among which there was only one fatal case. All the cases were dressed according to Lister's method, and the one fatal case could, he thought, be traced to an imperfection in the dressing. Since this method was introduced, purulent infection had disappeared from his wards, and cases of erysipelas were very rarely met with. M. Boinet stated that he had seen Demarquay employ Lister's method, but without success. According to M. Lucas-Championnière, however, Demarquay did not apply the dressings properly. L. regarded the drainage tube as an integral part of Lister's dressing, not to carry off pus, but the excess of serum, and so prevent the occurrence of tension. He denied that other methods of treatment produce equally favorable results. The union of almost the entire wound by first intention, without suppuration, occurred in his experience with extraordinary promptitude under this treatment.—*Journal de Méd. et de Chir*, March, 1876.

Lymphorrhagia Consecutive to Suppurative Adenitis and Lymphangitis.—The following are the conclusions of a paper on this subject by Dr. Deprés:

1st. Suppurative adenitis and suppurative lymphangitis are generally followed, for twenty days after the opening of the abscess, by a flow of lymph that retards the cicatrization of the incision.

2d. This flow of lymph may assume enormous proportions, and constitute a *lymphorrhagia*.

3d. The lymphorrhagia consecutive to a suppurative adenitis is more considerable than that following a suppurative lymphangitis.

4th. The more or less abundant lymphorrhagia is the real cause of the fistulas consequent on suppurative adenitis in healthy or scrofulous subjects.

5th. Compression, where it is applicable, arrests the lymphorrhagia in a few days; and where compression cannot be used, cauterization will arrest it, but more slowly.

6th. The flow of lymph and the lymphorrhagia after suppurative angeioleucitis and adenitis are a perfect demonstration of the primitive lesion of the lymphatic glands and vessels, and confirm the theories of Velpeau on this point.

7th. Finally, it follows from the above, that compression applied for several days in suppurative adenitis and angeioleucitis is the best means of preventing the occurrence of lymphatic fistulas.—*Gazette Médicale de Paris*, March 18th.

The Fœtal Souffle.—M. Pinard, *chef de clinique*, after noting the results of auscultation in pregnant women, with the view of determining the fœtal souffle, prepared a series of umbilical cords which he classified as follows:

1st. Cords from women in whom no other than the uterine souffle had been heard.

2d. Cords from women in whom only a pulsatory murmur with maximum over the fœtal heart was heard.

3d. Cords from women in whom he had made out a transient fœtal murmur, with its maximum sometimes over the site of the fœtal heart, sometimes at a greater or less distance from it.

4th. Cords from women in whom he had heard a simple, permanent murmur, with its maximum removed from the fœtal heart.

5th. Cords from women in whom he had heard a double, permanent fœtal souffle, with its maximum at a distance from the fœtal heart.

These cords were washed, insufflated, dried, and then examined for valves, with the following results:

In the cords of the three first categories, there were no traces of strangulation, and no folds, either semi-lunar or diaphragmatic. The vessels of some were almost rectilinear, of others more or less spiral, presenting rudiments of valves, either in the vein or the arteries, or perhaps a slightly moniliform appearance.

In the fourth category, which comprised but three cords, he found falciform, semi-lunar, or diaphragmatic folds, sufficiently large to obstruct a third, a half or even more of the lumen of the vein. The arteries presented constrictions, but the folds were absent or scarcely visible.

In the fifth category, which contained five cords, numerous well-developed folds, sometimes semi-lunar, sometimes diaphragmatic, were found, both in the vein and the arteries, and some of them obstructed at least three-fourths of the lumen of a vessel. These valves were most numerous close to the placental insertion of the cords.

In face of these results, the relation of cause and effect can hardly be denied, and from them the following conclusions may be formulated: When auscultation is carefully practised on the pregnant female in the latter half of pregnancy, three varieties of fœtal murmurs may be heard:

1st. A murmur corresponding to the first sound of the fœtal heart, which is muffled instead of being sharp and distinct. This is a cardiac murmur, is permanent, and disappears some hours or days after birth.

2d. A murmur with its maximum at a greater or less distance from the fœtal heart. This is a funicular souffle, which may be single or double, and is due to the presence of well-developed semi-lunar or diaphragmatic valves, either in the vein or the arteries, or in both varieties of vessels together.

3d. A single, transient murmur, isochronous with the pulsation of the fœtal heart, but stronger than either of the above varieties. This funicular souffle is due to a passing compression of the elements of the cord, either by the fœtal parts themselves or by the stethoscope.

In a note, the author states that, though he has examined some hundreds of cords, he has never found true varicosities of it, but only a moniliform appearance, due probably to constrictions of the vein or arteries.—*Gazette Médicale de Paris, March 18th*, 1876.

Uterine Calculus.—Dr. Luigi Felici was recently called on to treat a young woman, aged 31, who has been suffering for some time from irregular but abundant hemorrhages, pain in the back and other symptoms of uterine derangement. Digital and specular examination revealed a calculus fixed in the cervix uteri, and which was easily removed. Dr. Berti, in presenting the specimen to the Palermo Academy of Médicine, maintained that the existence of uterine calculi must be admitted, because their macroscopical, microscopical and chemical characteristics differentiated them from degenerated and calcified neoplasms. —*Gazette Médicale de Paris, March* 18.

The Entrance of Air into the Veins.—M. Couty has recently performed a series of experiments on this subject, from which he has deduced the following conclusions:

1. Air, after penetrating into the veins, does not pass into the vertebral arteries; even if it did, the phenomena would be the inverse of those actually

observed; the arterial tension would be at first increased, and not diminished.

The air does not paralyze the right side of the heart; mechanically and chemically, it excites it to contract, and the action of the heart continues until after the voluntary and respiratory muscles have ceased to act.

The arrest of the circulation is not due to an obstruction of the pulmonary capillaries by the air. Such an obstruction might produce a diminution of the aortic wave, but not the almost instantaneous arrest of it that sometimes occurs.

II. After disposing of the above ancient theories, he divides the symptoms of the accident into four periods, as follows:

First period.—Diminution of the aortic wave and fall of arterial tension; accelerated action of the heart.

Second period.—More decided diminution of tension; accelerated respiration; syncope, with falls, cry, pallor, dilatation of the pupils, etc.

Third period.—Aortic current almost *nil*; irritation of all the motor nervous centres; contraction and convulsive movements of the voluntary muscles; contraction of the involuntary muscles; evacuation of the urine and fæces; finally, very slow, deep and apoplectic respiration.

Fourth period.—Arterial tension *nil*; death of the brain and cessation of the convulsions; then, arrest of the respiration; last of all, cessation of the heart's action.

The general symptoms of the second and third periods, caused by anæmia of the nervous centres, will occur more or less rapidly, according to the rapidity with which the air is introduced, and will be more or less marked, according to the condition of the animal.

III. The air arrests the pulmonary current by a mechanical interference with the heart's action. It accumulates more or less rapidly beneath the convex wall of the organ, and, by virtue of its elasticity, distends the very expansive walls of the right ventricle, until the volume of the cavity is double or three times the normal. On this distention all the consecutive phenomena depend.

1st. The force of the heart's contraction remaining the same, while the resistance augments with the distension of the right walls, the auriculo ventricular contractions, normally incomplete, become more so, especially in the auricle.

2d. The walls, contracting on a gas instead of a fluid, compress, instead of driving it forward.

3d. The orifices of the distended right heart gape widely, and the auriculo ventricular contractions force the air through them into the venous system, even as far as the crural and encephalic veins. This voluminous inverse current begins as soon as the cardiac distension passes certain limits, and in fatal cases lasts until the cessation of the heart's action. To sum up, the air distends the cavities of the right side of the heart, and this distention, like other dilatations of the same cavities, produces cardiac asystole, with diminution of the aortic current. This asystole, however, is of a special nature; it is acute, sudden in its onset, and may be so marked that the pulmonary current is almost instantaneously cut off.

After discussing the various therapeutic measures proposed for this accident, the author recommends especially two: blood-letting, which, in diminishing the venous pressure, diminishes also the cardiac distension, and is useful in all cases; and inhalations of oxygen, which, by causing exosmosis of the nitrogen dissolved in the blood, facilitate the dissolution of the air which remains accumulated in the right heart.

These experiments have proved beyond doubt that the entrance of air into the veins, an accident very complicated in appearance, can be resolved into two functional derangements—one local and entirely mechanical, *i. e.*, distention of the cavities of the right side of the heart, producing cardiac asystole; the other general and consecutive, *i. e.*, the slowing or arrest of the circulation.—*Le Mouvement Médical, February* 19.

On the Influence of Erysipelas on Syphilis.—A case is reported by Dr. A. Dealma, of Freiburg, which appears to support the opinion of numerous French observers as to the curative action of erysipelas upon syphilis. A patient was received into the hospital on Nov. 25th, in the sixth week of a maculo-papular syphilide, which covered the whole body and was accompanied by high fever. There were also chancres on the foreskin, and other syphilitic manifestations. In addition to this, the patient had long had a chronic inflammation of the left elbow joint with fistulous openings. He was given four small hypodermic injections of corrosive sublimate on successive days, which produced no appreciable effect upon the eruption. Then, on Dec. 3d, an operation was performed upon the diseased elbow-joint to improve the position of the arm, and within a few hours he was found to have erysipelas in that region, doubtless contracted from another patient. This disease extended, and lasted with considerable severity until Dec. 19th, when it subsided. But as early as Dec. 10th, the seventh day of the erysipelas, all traces of the syphilis, with the exception of faint pigmentation of the skin, had wholly vanished. He remained free until Jan. 17th following, when a scanty roseola appeared, without fever. It affected no place, however, which had been the seat of erysipelas. Again, on Feb. 4th, there was a mild attack of erysipelas, followed on the 7th by a new and complete disappearance of the syphilitic eruption. The patient had no further manifestation of syphilis up to the August following, and meanwhile his general condition was so good that in March a resection of the elbow-joint was performed with an entirely satisfactory result.—*Vierteljahrsschr. für Derm. und Syphilis, III.*, 1, 1876.

Permanent Change in the Color of the Hair and Skin after Scarlet Fever.—Dr. Wallenberg, of Dantzic, reports the case of a young man of twenty-one, who had an attack of scarlet fever followed by an unusual desquamation, in which over almost the whole surface of the body the epidermis was raised by exudation from the rete Malpighi, having this exposed in places as large as the palm of the hand, and in places covered with mucous crusts. Some small abscesses also formed. Subsequently he lost completely all the hair from every portion of the body; and where it grew again, instead of being dark brown as before, it was white, as in an Albino. The tint of his skin, too, changed from brownish to milk white, with a reddish tinge. The microscope also showed its condition to be completely analogous to that of the Albino. The cause of this loss of color, which has now lasted seven years, Dr. W. attributes to the destruction of the pigment cells of the skin and hair-cells by the profound inflammatory action. The skin has also remained extremely irritable, as shown by the occurrence of several outbreaks of general eczema after comparatively slight irritations.—*Vierteljahrsschr. f. Derm. u. Syphilis, III.*, 1, 1876.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, April 29, 1876.

THE NECESSITY FOR STATE BOARDS OF HEALTH.

THE necessity for State Boards of Health can hardly be questioned when we consider how much benefit may be derived from them. In a previous article, in which we proposed a simple plan for the organization of such boards, we only hinted at the good results which might follow. Let us, for the sake of continuing the discussion upon the general subject, glance at some of the more palpable reasons why such an organization is needed. As before remarked, there are a great many districts in this and in other States which have no sanitary provision for the emergencies of an epidemic, or for the prevention of those telluric influences which are so invariably found to associate themselves with high death rates. It must be admitted that considerable sanitary regulation could be enforced by a special board acting under the authority of the State, and created for an emergency; but if we look at the matter merely from this point of view, we must be satisfied with only a temporary remedy for unsanitary conditions in these localities. We are, however, under the authority of a general state board, able to extend the benefits to sanitary regulations far beyond these requirements. The State itself can be made the theatre of the operation of the general board, after the same manner as are the larger towns by their respective local boards. Here the broad principle of the common good is made paramount to local or individual interests. Take, for instance, the much vexed question of drainage on a large scale, and the great benefit which its proper and systematic regulation might effect. In this as in every other State there are lands which are little better than pestiferous swamps, which, during the warmer seasons, exhale malaria and other poisons sufficient to infect whole neighborhoods. To encroachments of civilization, and the attendant increase of population, are year after year making these poisons relatively more virulent, and yet, for the want of a general and practical remedy, the population annually sicken and a number of unnecessary deaths occur. The enforcement of a proper authority could remedy this evil in a few years, at the same time there would be an increase in the wealth of the agricultural districts which would repay the expense in a tenfold ratio. The larger the tract of land requiring to be drained, the greater the number of different townships situated in such an area, the more the necessity for some centralized State authority which shall adjust all differences of opinion of local authorities to the standard of the common good. It would, indeed, be impossible to meet the emergencies in any other way. There is a great deal of work to be done, it is true; but we must be prepared to make a beginning somewhere. The State authorities understood the merits of the general question of State jurisdiction in regard to the water supply of our city, and have acted accordingly. In no other way could we be assured that our drinking water would be free from the chances of ordinary contamination. A striking example of a neglect to look after a similar matter caused the melancholy epidemic at Eagley, and the possibility of its repetition in some other localities is causing the deepest anxiety among the sanitarians of Great Britain. But we must be prepared to go beyond a local jurisdiction beyond the care of a limited portion of the State for a given purpose, and extend a general jurisdiction to the entire commonwealth. Drinking water is liable to contamination in other parts of the State; the rivers which run through scores of counties must be kept in sanitary conditions, so that the sewage of one village does not mix with the drink of another.

The railroads, too, are not entirely free from evil effects upon the health of the people along the line. Many matters in connection with them deserve the attention of a board which shall have the power to enforce requirements, not only in a given locality, but throughout the entire route. There are many instances in which the building of a railroad has so altered the drainage of a district, that malarial diseases prevail, where before they had never been known. Although we have no very glaring examples in our own State, the history of the towns along the line of the Hudson River Railroad is sufficiently suggestive of the truth of this assertion. In many places between this city and Albany there are collections of stagnant water along the line of the track, which are covered during the whole season with a pestiferous scum, capable of supplying malaria to every passenger on the road. This is in the main due to the grading of the road, which in many places so directly interferes with the drainage as to create what would otherwise be rippling brooks into stagnant pools. The same complaint might be made of the other railroad lines

throughout the State. No local health board could deal with such an evil.

There are many other subjects to be taken into account, in connection with the beneficial working of a State board such as we propose. Not only is it the province of a health board to look after the purity of water, but to guard against any chances of its diminished supply. It is well known that the forests hold a very important relation to the latter condition, and that their destruction accounts in a measure for the droughts, the consequent exposure of brook and lake beds, and the general scarcity of water at the time of the year when it is most needed. The proper care of the forests has long ago been a matter of great concern with sanitarians in Europe, and has necessitated legislation upon the subject. Already, in this country, efforts are made in the same direction; and in this State a bill is pending for the creation of a Commission, whose duty it shall be to prevent the wholesale destruction of trees. If such a commission be created, it would obviate the necessity for the interference of any health board, or for the exercise of an authority which might legitimately devolve upon it.

Since it has become the fashion throughout different portions of the State to establish religious camp grounds, we have another argument in favor of a central State board. The local authorities seemingly have no power to enforce any of the necessary sanitary regulations upon these corporations; and the consequence will be that, ere long, many of these grounds will be transformed from health resorts into so many centres for the propagation of diseases. At present there is no other guarantee for the proper sanitary care of the camp people, than that which may be centred in the whims of an executive committee. In many instances, the salvation of the pilgrims has been secured by their short sojourn in these localities. By-and-by even this immunity will not obtain. The soil must become sooner or later saturated with sewage, the water become contaminated, and low forms of fever be propagated. But we need not multiply examples to prove the necessity for the existence of a State board having the necessary authority to act on all questions of similar import. Every one who has given the subject any attention at all can amplify the list, so that it shall comprise all the reforms which, under present circumstances, it is impossible to attempt.

PRESIDING OFFICERS FOR MEDICAL ASSOCIATIONS.

The Kentucky State Medical Society, at its recent annual meeting, adopted a resolution to the effect that its Committee on Nominations shall hereafter not consider themselves bound to present for the Presidency the name of a physician from the locality where the Society meets. This is a very sensible measure, and will in the future tend to remove much of the embarrassment under which such a Committee may labor, and tend to an impartial distribution of the honors, and the selection of truly representative men. If the same resolutions were adopted by other similar organizations, much dissatisfaction would be prevented.

PRELIMINARY EDUCATION.

In the last announcement (1876) of the Portland School for Medical Instruction, Portland, Me., we notice the following significant provision:

"No person will hereafter be admitted to the school, who does not satisfy the Board of Instructors that he possesses at least a good common school education. The fact of graduation from college, or from a respectable high school or academy, is taken as sufficient evidence of such acquirements; but in the absence of a diploma, or certificate to this effect, a written examination will be held."

The regulation is, we understand, giving general satisfaction to all interested in the welfare of the college; and a better class of students is secured. This is as it should be, and shows on the part of the school a determination to respect the growing professional sentiment.

SMALL-POX SPREAD BY DOGS.

A rural sanitary organization in England, has applied, through Dr. Mackintosh (*British Medical Journal*), for an order from the magistrates to have all dogs in the district of Bolsover chained until small-pox has disappeared in that locality.

Dr. Mackintosh considers, and very properly we think, that "the disease is spread from house to house more by domestic animals than by anything else." We believe that the more this subject is examined from this point of view, the more the views advanced will be considered correct. It is possible also that the spread of other contagious diseases, such, for instance, as scarlet fever, may be explained in this way when all other recognized reasons have failed.

THE AFFAIRS OF THE HEALTH OFFICE.

The investigation of the affairs of the Health Office by the Assembly Committee on Commerce, have tended to place the health officer, Dr. Vanderpoel, in a very disagreeable light. Attention has been more particularly directed to his private yacht, "Gertrude," the running expenses of which appear to have been paid by the State in lieu of public services rendered. The testimony given before the Committee does not, we are sorry to say, place the doctor above the suspicion of using public money for private purposes. The cost to the State of the "Gertrude," is said to have been over eleven thousand dollars, and yet the whole amount received for earnings of all the boats, the "Hopkins," the "Fenton," and the "Gertrude," during the year was but seven hundred and ninety dollars. We sincerely hope that this

is not true, and that Dr. Vanderpoel may have some good reason for the course he has taken, and effectually explain what to his friends, who have the utmost confidence in his honesty, seems past comprehension. A character such as the health officer has earned for himself as a gentleman of the highest integrity, is not to be easily overthrown, and we are still hopeful of vindication.

Reports of Societies.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, March 22d, 1876.

FIBROMA OF VAGINA—REMOVAL BY ECRASEUR.

DR. C. K. BRIDDON, PRESIDENT, IN THE CHAIR.

DR. METCALF exhibited an egg-shaped tumor (¾in. × ½in.) which had been removed by the écraseur from the vagina of a patient aged fifty-two years. For four years she had suffered from "weakness" pain in the lower part of the abdomen and around the waist, occasionally accompanied with difficult micturition. The operation was performed in October, and the woman made a good recovery. The tumor was examined microscopically by Dr. Heitzmann, who declared it to be a simple fibroma.

DR. SELL had met with a similar case in an unmarried lady aged twenty-seven years.

OSTEOID CHONDROMA OF TIBIA—AMPUTATION OF THIGH.

DR. MASON next presented a specimen of morbid growth in the head of the tibia, removed by amputation of the thigh, February 22d, from a male patient sixty one years of age. The patient was seen, in in consultation with Dr. Van Geisen of Greenpoint, was strictly temperate, and had enjoyed excellent health until three years previous. At that time he received a blow upon the tibia, which produced very intense pain and laid him up for two or three days. He recovered from this, and had no further trouble until six months after, when he had a severe attack of pain in his knee, and another two or three days' confinement. After this he had similar attacks every two or three months. They were regarded as rheumatic in character, and were prescribed for accordingly. About two months ago an enlargement of the tibia was noticed, which was apparently due to a growth from the outer surface of the bone pushing the fibula outwards.

A few days before the operation, the patient, when Dr. Mason first saw him, was very much prostrated; the pain from which he suffered was so severe as to be only partially controlled by powerful anodynes. On examining the leg, which was partially flexed, the presence of a morbid growth was at once discovered. The surface was very sensitive to the touch, but, contrary to expectation, did not give any egg-shell crepitus. The diagnosis of osteo-sarcoma was made, amputation advised, and the section carried through the tumor, just above the condyles.

The tumor had been handed to Dr. Delafield, who made a verbal report:

The external surface of the tumor, which involved the head of the tibia, was composed of cartilage. The basement substance of cartilage was partly hyaline and partly fibrillated. The cells were of a somewhat irregular shape, as they were apt to be in new growth of cartilage. In the enlarged portion of the head of the tibia, there were scattered nodules of cartilage which varied in size from the point of a pin to that of a chestnut. Some of these nodules were quite near to each other seeming almost to fuse together. Other abnormal appearances in the enlargement were due to a growth of connective tissue, and of cells in the medullary spaces between the bone, which also contained a number of blood-vessels. The fat which should have existed in the medullary spaces was almost entirely absent. The development of new cartilage was not confined to the medullary spaces, but invaded the bone cells and the basement substance of the bone, itself. The bone cells were considerably enlarged, many of them containing two or more nuclei, and, becoming fused together, to form a cavity of some size filled with cells. When this occurred near the edge of the bone, a little cavity would be formed communicating with the medullary spaces. The cartilaginous growths originated from the periosteum, and also from the medulla of the head of the tibia—in other words, the growth was an example of osteoid chondroma.

MYXOMA OF AXILLA.

DR. BRIDDON presented a specimen of Myxoma of the Axilla with the following history, from Dr. C. B. Roof, House Surgeon:—

Benjamin Brennan, æt. 18, United States—Grocer—Admitted March 7th, 1876. About six months ago the patient first noticed a small lump situated midway between the left nipple and the coracoid process of the scapula, which has grown steadily ever since; he would have paroxysms of sharp stinging pain, which would last about fifteen minutes in the tumor, and then pass down the side and arm. Father and mother are both living, and he gives no history of any hereditary disease whatever.

The left axilla was entirely filled with a large mass about the size of the fœtal head; it reached to the lower border of the clavicle above, covering in the coracoid process, and bulged the floor below; it was immovable, and appeared to be fixed to the thoracic boundary of the space; there was no evidence of pressure on the plexus of vessels and nerves; its anterior surface was covered by the pectoral muscles, and it did not appear to have any attachment to the scapula; dilated veins meandered over its surface, and to the touch it presented the soft, elastic feeling characteristic of malignant disease.

Operation March 9th, 1876, in the presence of the Hospital Staff and a number of medical men. After complete anæsthesia, the arm was extended, and a long incision carried from the thoracic to humeral extremity, midway between the anterior and posterior folds of the axilla; the dissection was continued through the subcutaneous fat and fascia, until the surface of the tumor was exposed, when the knife was laid aside, and an attempt was made to enucleate the mass with the fingers. This was found, however, to be almost impracticable; the capsule did not form a complete investment, but everywhere at the circumference appeared to merge into the fascia immediately investing the walls of the chest; all the soft parts, forming the anterior wall of the space, were separated as high as the inferior border of the clavicle; below it was found necessary to divide a portion of the great pectoral muscle, and this was done at its point of origin from the ribs; thus the whole mass was exposed, and found to be firmly adherent to the thoracic wall. In attempting to separate these connections, the aponeurotic investment gave way, and it was found that the mass of soft cerebriform consistence, was continuous through

the intercostal spaces, with growth of the same character within the cavity of the chest itself. The pleural sac itself was not opened; the intrathoracic portion appeared to be situate between the pleura and the chest walls; the ribs were eroded and depressed over the area that had been occupied by the tumors; everything was cleared out of the axilla, and in doing this a large vein was opened and secured; the oozing from severed isthmuses that had been the bond of union between the axillary and thoracic portions of the growth was treated by the application of charpie and persulphate of iron, supported by compress and bandage.

The amount of blood lost during the operation was very great, and the exhaustion of the patient of a pronounced character.

March 10th. Patient has passed a quiet night, but this morning he complains of a sharp pain in the left side, for which he was given teaspoonful doses of United States solution of morphia at intervals of two hours, which seemed to allay the pain.

March 11th. Patient has been delirious all night, and pain in the side is increasing; respirations short and quick, with a dry, hacking cough; he was given a hypodermic injection of ten minims of Magendie's solution of morphine, after which he became quiet. Immediately after the hypodermic injection, patient's body became bathed in perspiration. This line of treatment was continued at intervals of four hours, until ten o'clock P.M., when he became unconscious, and about one A.M., March 12th, he expired.

Microscopic Examination by Dr. T. E. Satterthwaite, Pathologist to the Hospital.—The portions sent for examination were exceedingly soft and jelly-like—much like half-set jelly.

After immersion in Miller's fluid and alcohol, it became firmer, so that sections could be made from it. It was then seen that the tissue was made up of a large variety of corpuscles, some stellate, some spindle-shaped, some ovate, and others round, the corpuscles embedded for the most part in an amorphous substance, though in a few places there were fibres between the corpuscles. Vessels were quite common in the tumor, and blood-cells were extensively extravasated in most of the parts examined. Since the corpuscles had undergone mucous change.

Judging from the prevailing character of the tumor, it should be regarded as a myxoma; in a few places there were sarcomatous elements.

Dr. Gibney exhibited portions of the dorsal cord removed from the carious vertebral column of a boy eight and a half years of age, who died of catarrhal pneumonia. The spinal disease had its origin in a fall at the age of three years, and resulted in a sharp angular curve in the dorsal region. The point of interest in the case was, the entire absence of any evidences of pachymeningitis, the result of pressure on the cord. Far from this being the case, the canal, at its angle of bending, was rounded off, entirely guarding against any chances of pressure. A residual abscess, containing a cheesy mass, was discovered on the right side of the tenth dorsal vertebra.

No other members having specimens to present, the Society went into executive session.

Statue to the late Sir James Y. Simpson.—The statue which is to be erected in Princes Street Gardens, Edinburgh, to the memory of this distinguished physician, will probably be ready for transportation in June next.

Correspondence.

MEXICO AS A RESIDENCE FOR INVALIDS.

Letters from Prof. E. R. PEASLEE, M.D.

II.

City of Mexico, *March* 13, 1876.

Mr. Editor:—I now proceed to matters of more exclusive interest to our profession, and to those, invalids or otherwise, who contemplate making this city, or this country, a winter residence.

Situated 19¼° north latitude, Mexico is at an altitude above the sea level, as I find by reference to the railroad survey, of 7459.7 feet. The air is never cold, to one clad in a medium winter suit for New York, and is not uncomfortably warm, except on direct exposure to the sun. During the past three winter months, the indoor temperature in this hotel, (the Iturbide) was never below 58° of Fahrenheit, nor above 63°. During the hottest months—March and April—the average indoor temperature, as found at the American legation, is 68°. The nights are cool the year round, and frost is not very uncommon.

Rain falls here but seldom, except during the rainy season, which continues from June till October, excepting about two weeks in August. It then recurs daily at 3 to 4 P.M., and generally continues one or two hours, and sometimes into the night. During the past winter, however, there have been six showers, and another occurred since my arrival here. There has been no cloudy day, and only on four days has the wind been unpleasant. On six days only were rubbers required, and this merely to keep the soles dry. These data are given me by a very intelligent gentleman, who has spent the winter here.

Thus the weather is so regularly clear and fair, with the modifications just explained, that it is not a common topic of discussion or remark, as almost everywhere else; but the statement that it is never so is unfounded.

The rainy season is the most healthy part of the year. But there is at all times a peculiar dampness within doors, and which in the very sensitive is liable to produce a sensation of chilliness. There are two facts to account for it. (1) The present city of Mexico was built upon ground formerly covered by Lake Tezcuco, and into which it is drained. Thus the drainage is very defective, and the ground is saturated with moisture from the surface downwards. Indeed, soft mud is found less than two feet beneath the pavement. And, since cellars are here unknown, the dampness permeates every part of the house; and (2) is never removed, since fires are never used—with perhaps half a dozen exceptions in the whole city—either in sleeping-rooms or parlors. This dampness is, therefore, never overcome, except so far as it may be modified by the admission into the apartment of the sun's heat, and which of course, can occur only in case of those having a favorable exposure. The difference in a sanitary point of view between apartments having such an advantage, and those unvisited by the sun, is recognized in the fact now generally understood that the houses on one side of a particular street are very unhealthy, while those on the opposite side are quite healthy, *e.g.*, those on the north side of the Calle de Plateros are known to be healthy residences, while those on the south side seem to be almost pestilential.

It is against this dampness and chilliness that the stranger must be especially on his guard. And as he

is more liable to the latter on returning to his room after out-of-door exercise, he will find it judicious to sit in his apartment, especially if it be in the shade, with an additional covering, as a cape or a shawl. While walking the streets, it is better to keep the shady side; but if once on the other, to use an umbrella, and not cross when very warm into the shade. The direct rays of the sun must be avoided. Sunstroke is, however, here very uncommon.

Carelessness in these respects on the part of strangers is very likely to be followed by a fever of a typhoid type, which is not seldom fatal; and especial precautions should be taken when this fever is prevailing as an epidemic. One of the sons of Rev. Dr. Butler, the distinguished head of the Protestant Church in San Francisco street, died of this fever, and another son and daughter very narrowly escaped.

In consequence of the defective drainage and the dampness of this city, typhoid fever and pneumonia are annually epidemic; and these two diseases together, I am assured, produce more than half of its entire mortality. Its population is variously estimated from 210,000 to 300,000. I think 250,000 for the city proper, and 50,000 for the suburbs is a sufficiently liberal estimate. But at any rate, the epidemic of typhoid fever of the last season carried off 8,000 (some authoritiessay 10,000) persons; or at least 3,2 to 4 per cent. of the entire population. The deaths from pneumonia were probably not less numerous. Typhoid is epidemic in March, April, May and June, but sporadic cases occur throughout the year.

During the past winter also very many children were destroyed by an epidemic of "throat disease," and which I believe to have been unrecognized diphtheria. Neuralgic affections and paralysis are also quite common. Rheumatism occurs more frequently in foreigners.

Mexico, therefore, cannot be regarded in general as a healthy city; and until a better drainage is secured —an immensely expensive enterprise long ago commenced, and probably not for the next fifty years to be completed —it must become less so. But the main question, and which I next consider, is its merits as a resort for those suffering from chronic pulmonary affections in the Northern parts of our Union. Such patients are necessarily absent from home from about November 1st to the first of May, or later, and would be in this country during the three winter months, and March also, perhaps; taking the trip leisurely to this city and back to New York. They would thus avoid most of the time when the epidemic of typhoid occurs, though pneumonia especially prevails during the winter months.

Since the whole ascent of 7459 feet from Vera Cruz to Mexico is made by rail in fifteen hours, as has been seen, and the ascent to the highest point on the road, 8318.5 feet, is made in about ten hours, many travellers, though in health, experience a decided dyspnœa on reaching these altitudes, especially on making any considerable muscular exertion, on account of the rarefaction of the atmosphere; though no amount of effort produces much sensible perspiration. The consequences in cases of pulmonary emphysema, or asthma depending on cardiac affections, are, as might be expected, not favorable. Asthma depending on derangement of the stomach, however, is sometimes here cured. Chronic bronchitis also, is not likely to be relieved at this altitude, combined with the dampness I have mentioned. But all these are alleviated by a residence at a lower altitude, the point suitable for such cases being found at Vera Cruz, or between that city and the altitude of Cordova or Orizaba, *i.e.* 2700 to 4000 feet.

Phthisis is not indigenous in this city, and it is not seldom arrested in those who come here from the North. A member of the Mexican Congress assured me that the natives do not die of phthisis, and that the lives of phthisical patients from the North are usually much prolonged by a permanent residence here.

I have, however, satisfied myself that while all this is true, and while this city is a very delightful residence for Northerners in health, and who take the precautions to maintain it, it presents no special advantages to phthisical and bronchitic patients. I cannot recommend it, therefore, to such as a winter residence.

But there are other places of lower altitude in this country which I believe to be fully equal, and in some respects even superior to any of the famous resorts abroad I will mention, as on the railway from Vera Cruz, Cordova (altitude 2715.5 feet) and Orizaba (4030.7 feet); both presenting a tropical climate, and all its productions, and the most grand and picturesque scenery. Cordova has, however, sometimes been visited by yellow fever. Jalapa, also now accessible by another railroad from Vera Cruz, is doubtless equal to either of these places as a sanitarium for this class of patients; and as a residence is one of the most beautiful places on earth. Its great humidity may, however, render it unsuitable to some cases, and the sudden chill of the northers must also be guarded against in these places. But Cuernavaca, sixty miles south of this city, and not accessible by railroad, has an altitude of 5428 feet, and the same climate and productions as Orizaba; and is far more desirable. In addition to these places, Dr. F. Semeleder, of this city, formerly physician to the Emperor Maximilian, mentions Tetecala, not far from Cuernavaca. Atlixco, 23 miles from Puebla, is also recommended, as well as Monterey, though the latter is accessible only by a tedious journey by diligence.

But I must bring this communication to a close; and will only add that the expense for medical attendance in this city is as follows: To those abundantly able to pay, $2 per visit, if made daily; and $3 or $4 if made but seldom, as in chronic cases. Consultation visits are $10 to $20, according to circumstances. The charges, however, average considerably less than this, and in all the other places I have named is not over $1 per visit. Very little quinine is prescribed here, and in the epidemics I have named iron is very much used; but, with this exception and arsenic, the vegetable remedies are, I am told, generally preferred.

E. R. Peaslee.

PROFESSIONAL RESPONSIBILITY IN PRODUCING ABORTION.

To the Editor of the Medical Record:

Dear Sir: In the last number of your journal, there is a letter upon the subject of criminal abortion and abortifacient drugs, signed "C.," which suggests a few words in reply.

In answer to the question as to the "properties of aloes" we will quote from a few well-known authors.

Ringer says aloes acts mainly on the large intestine and rectum; by its action on the rectum it sympathetically affects the neighboring pelvic organs, as the uterus; and is useful in many cases of amenorrhœa and deficient menstruation.

Headland says, aloes appears to act on the lower part of the intestine, and is therefore objectionable in cases of pregnancy or of uterine disorder.

Scanzoni classes aloes with savin and ergot, as a

medicine capable of determining the blood towards the organs of the pelvis, while

Barker, in his work upon the *Puerperal Diseases*, says that he has for many years given aloes to pregnant women, with a tendency to hemorrhoidal affections in sufficient quantity to secure one easy, free daily evacuation of the rectum.

From these statements, we conclude that aloes may be given in some cases of amenorrhœa with advantage; and that although it acts upon the rectum, and the uterus, it has been found useful and safe to administer it in certain conditions arising during pregnancy. We believe the same is true of ergot, savin, and digitalis; hence we see no reason for considering any one of these medicines an abortifacient. They are, indeed, often of the greatest service in checking a tendency to abortion; but much discrimination should be exercised in the choice of cases for which they are applicable.

Let us now review the "circumstance" which you related to the attorney, beginning with the words "some few years ago." The case is briefly as follows: A married woman had not menstruated for "over three months," and her husband applied to you for medicine to "make her turns come regularly." Without becoming in the least degree familiar with her condition, in fact without seeing her, you prescribed a "compound, the basis of which was aloes." This is the form of practice we are constantly condemning in the unprincipled druggist—the medical impostor, and the advertising abortionist. In most cases, indeed, they are compelled to exercise more care than was shown by you in this case. For should disastrous results follow, they cannot take refuge in a learned diploma, nor call upon the medical profession to "help them out."

We do not pretend to know what your object was in prescribing this compound; but if, as we infer, you desired to restore the menstrual flow, you might with equal and even greater propriety, have made use of other means; as, for example, the injection of hot water into the vaginal canal—the stimulating foot-bath—local applications to the cervix uteri passage of sound into the uterine cavity, &c. for these are methods indicated in many cases of amenorrhœa, and we confess surprise that you did not resort to one or more of them. Probably, however you have tested your "compound" so frequently under similar circumstances, as to have complete confidence in its sufficiency. Sure enough, in eight or ten days you were summoned to see your patient—the courses which had been absent for three months and over had returned. Happy result! What an excellent compound! But your attention is called to something else, and you rupture the sac (a most laudable procedure, for it marks the beginning of careful practice). Then you tell your readers you "discovered a fœtus" at least three months old. The diagnosis was a good one, but made rather late. You should have discovered it ten days before, within the uterus.

Now we do not accuse you of criminal intent in this matter; we are not even prepared to assert that your "compound, the basis of which was aloes," produced the abortion. You cannot, however, be too severely blamed for administering this drug, at random, while in entire ignorance of the woman's condition. Such practice is an abuse of professional power, and if the medicine you gave was the cause of, or increased in any degree the tendency to, this abortion; or if by previous knowledge of her condition, you could have by advice or medicine preserved the life of the fœtus—then are you partly responsible for its death.

Ignorance does not excuse you; since it was here your special office as a physician to investigate and know; and whether "this fellow" (the husband) designedly or innocently misrepresented the facts, does not in the least alter your responsibility. If you were duped, so much the worse.

One word in conclusion: your reference to abortionists and their numerous followers throughout our country suggests a remark, by way of admonition to our profession. Let us remember, that the number of *criminal* abortions is insignificantly small, as compared with those produced by disease, and although we are familiar with many of these diseases, yet we have not made ourselves masters of them. Moreover, recent investigations plainly indicate that we have as yet learned to recognize only the very smallest percentage of actual abortions; that abortions chiefly occur at the first or second month, and pass unnoticed. In view of these facts, and their important practical bearing, what a great demand is made upon the physician for earnest and devout labor in this department of science.

Again, in our relations to families as guardians of health and life, are we doing what we can to prevent the accidents and dangers to which fœtal life is exposed?

Especially let us be on our guard lest, by careless medications, we be often made unwilling participants in the crime of infanticide.

Yours truly, H.

SALICYLIC ACID IN RHEUMATISM.

To the Editor of the Medical Record.

Sir:—Will you please give a small space in your journal to the following case:—

Mrs. Voorhis, aged 54, of a nervous and lymphatic temperament, weakly and emaciated, was for several years subject to general bronchitis and occasional attacks of articular rheumatism. On February 18th, she was taken ill with polyarthritis rheumatica, in the finger joints of both hands; 24 hours after, suddenly jumping from one articulation to another, invading in 48 hours all the joints of her body.

Treatment:—First of all, the caustic ammonia, highly recommended by Dr. Franz Heller, was faithfully tried, but failed.

Having read of the good results obtained by Dr. Stricker with the Salicylic Acid, lately introduced by Dr. Traube, and having failed with all other known remedies, on March 30th, I determined to give it a trial. Its result was gratifying to me; for the patient was relieved of her so long-endured, excruciating pain in a few hours. The quantity prescribed was two drachms, divided into sixteen powders, which were given in wafers, one every hour. After the fourth powder the pain commenced to subside up to the thirteenth, when, being completely freed from it, she fell into a refreshing sleep, of which she had been deprived for many days, and which she now enjoys for several hours. On awaking, the swelling and heat of each joint, and the contraction at the knees had gone, and she was able to walk. The action of the remedy was somewhat peculiar. From the fourth dose was observed a marked degree of coldness all over the body, and a warm sensation internally. After the sixth powder the periphery of the body became quite cold, and dripping with a profuse and acid perspiration, particularly from the head. At the thirteenth dose, just before going to sleep, the thermometer fell from 106°, which it was previous to the use of the acid, to 96°, remaining so for ten hours—six hours while asleep, and four after waking. On her awaking, she remarked that the tip of her nose and lower

extremities were painfully cold. The internal heat, though, according to the patient's statement, particularly at the region of the stomach, was simply unbearable; yet the tongue and breath were very cold. The pulse, from an average of 100 during the forty-one days of rheumatism, rose to 150, very thready and readily lost under a slight pressure at the wrist, and the respiration 30?; continuing so together for six hours. During the time, she was complaining of internal heat and the want of fresh air. She was very much excited, and was begging me in a very feeble voice not to leave her bedside, fearing she should die. In fact, in view of the above train of symptoms, and not being well acquainted with the action of the acid in similar cases, and at such quantity, I felt very much alarmed at her condition; but whiskey, generously used, aromatic spirit of ammonia, hot bricks round the body, and warm blankets, after several hours of dreadful anxiety, removed the unpleasant algid state, and things assumed a more favorable aspect. In addition to the above symptoms, after the fourth dose, tinnitus aurium commenced, with a total loss of hearing; the former lasting six hours after the discontinuation of the drug, and the latter twenty-four hours. Although the patient was without pain twelve hours after its disappearance, the acid was resumed for four days longer at seven grains every six hours. At each dose a decrease of temperature was observed, about 1½ degrees, and the return of pyrosis for a short time only. Had she been strong, very likely the symptoms above narrated might not have occurred.

I have used the acid in seven grain doses every four hours in the case of another woman, 36 years old, afflicted with chronic rheumatism and swelling of the ankle-joints, with a similar result, and reduction of swelling. My patients, so far, eleven days after the use of the acid, are free of pain, notwithstanding the atmospheric changes. From what has been said by Traube, Stricker, and other distinguished writers, and from my own experience of this one instance, I am fully convinced that salicylic acid cures inflammatory rheumatism, no matter how; and unless I should hereafter be disappointed in similar cases, I shall avail myself of its efficacy. While, however, the effect produced by both quinine and salicylic acid are in some respects identical; still, the distressing pyrosis and acceleration of the card ac organ, caused by the latter, would forbid my using it as a febrifuge.

Respectfully yours,

S. Cabo, M.D.

DR. MUNDE'S REPORT ON GYNÆCOLOGY.

To the Editor of The Medical Record.

My Dear Sir: Will you permit me to correct an error in the account contained in your issue of the 15th inst., of my annual Report on Gynæcology, read before the Medical Journal Association on the 7th inst.?

Speaking of the Physiology of Ovulation and Menstruation, your reporter says: "Dr. Mundé, however, did not accept this doctrine (the independence of ovulation and menstruation), and placed himself with those who believed that menstruation is an accompaniment of ovulation, according to the old theory."

By referring to my Report, published in the April number of the *Journal of Obstetrics*, it will be seen that I repeatedly take exactly the opposite ground, so far as is admissible in a paper of that nature. For instance, after describing the old theory, I say, "But, unfortunately, in the course of years, a number of incontrovertible facts have appeared, which cannot be made to correspond with it, and which prevent the indissoluble connection of menstruation and ovulation from being received as a law," etc. Again, "In view of these serious and insurmountable objections to this old theory," etc.

Now, while it makes but very little difference what opinions any man entertains on a subject on which he has no personal experience, and which he has not himself investigated; still, in this instance, I should prefer not to be placed on record as holding a view, in my opinion, directly contrary to the evidence, which I believe to be decidedly in favor of the new theory of the independence of ovulation and menstruation, after those functions have once become fairly established.

Yours truly,

Paul F. Mundé, M.D.

20 West 45th St., *April 17th*, 1876.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department of the United States Army, from April 16th to April 22d, 1876.

Baily, E. J. Surgeon, and Medical Director—Granted leave of absence for 30 days. S. O. 38, Department of the Columbia, April 3, 1876; and leave extended one month; S. O. 45, Military Division of the Pacific, April 12, 1876.

Medical Items and News.

Contagious Diseases.—Comparative statement of cases of Contagious Disease reported to the Sanitary Bureau, Health Department, for the two weeks ending April 22d, 1876. Walter De F. Day,

Sanitary Superintendent.

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro Spinal Meningitis.	Measles.	Diphtheria.	Small pox.
April 15th.....	0	8	103	5	72	75	29
April 22d.....	0	12	80	4	51	76	16

Sir William Wilde, of Dublin, is reported to be seriously ill.

Dr. John Brown, of Edinburgh, the distinguished author of "Rab and his Friends," "Spare Hours," and other works, has had conferred upon him a civil list pension of one hundred pounds per annum, in recognition of his literary eminence. This announcement will gratify the thousands of readers, in and out of his profession, who have enjoyed his classical productions.

Kentucky State Medical Society.—The annual meeting for 1876 was held at Hopkinsville, Ky., April 4. The following officers were elected for the ensuing year: Dr. R. W. Gaines, of Hopkinsville, President; Drs. C. H. Todd, of Owensboro, and L. S. McMurtry, of Darille, Vice Presidents. Dr. J. H. Letcher, of Henderson, Secretary; and Dr. A. D. Price, of Harrodsburg, Secretary. The next meeting will be held at Louisville, on the first Tuesday of

April, 1877. A full report of the proceedings will be found in the *Louisville Medical News* for April 15.

Street Pavements.—Gen. Q. A. Gillmore, in a work on the construction of roads, street pavements, etc., is strongly inclined to favor pavements of natural asphalt, as used in the streets of Paris, while he decidedly condemns the worthless inventions, erroneously called asphalt pavements, compounded with sand, gravel, or lime, and without any suitable cementing medium. This will, in his opinion, combine the two elements of greatest practical importance, durability and absence of noise from travel.

Dr. Samuel B. Ward, of this city, will remove to Albany in May. His numerous medical friends gave him a complimentary dinner at Delmonico's on the 25th instant.

The Harvey Statue.—Only £800 of the £3,000 required have been thus far obtained for the proposed statue at Folkestone.

English Army Medical School.—There is a report current in Great Britain, that the Army Medical School at Netley is to be abolished.

Beau-Ideal of a Consultant.—The *Medical Times and Gazette* (London), says: "Our beau-ideal of a consultant is one who, after a university or other liberal education, has worked hard when a student, has taken a good degree, and then settled down into private general practice; after some years of which, having meanwhile kept himself thoroughly *au courant* with the professional discoveries and improvements of the time, he abandons that branch and devotes himself to the cultivation of a consulting practice."

Dawson's *vs.* Piffard's Battery.—The typographical errors in the item of explanation with the above heading in the last number are such that we are compelled to make one more attempt to set matters right. By so doing we hope to avoid any lengthened discussion of the relative merits of the batteries by the gentlemen who are naturally the most interested. Since the appearance of the last number we have had the opportunity of measuring Dr. Dawson's plates, and obtaining from him certain explanations which enable us to present all the facts in the case. But first, in regard to the typographical errors referred to. We intended to state that Dr. Piffard's plates measured $5 \times 4\frac{1}{2}$ inches, and not "$5\frac{1}{4}$+ inches" as printed. Dr. Dawson, in his letter, was made to state the size of Piffard's plates as $6\frac{1}{2} \times 4\frac{1}{2}$, instead of $6 \times 4\frac{1}{2}$, a measurement which he says was based on Piffard's statement the evening of the meeting. Dr. D.'s statement that his platinum measured $5\frac{1}{4} \times 4\frac{1}{2}$ is a misprint (viz.: p. 260). Owing to an unfortunate ingenuity of the printer the quotation from Dr. D.'s letter, in our explanation, which should have been $6\frac{1}{2} \times 4\frac{1}{2}$ (erroneous as it was), was made still more so by printing it $6\frac{1}{2} \times 5\frac{1}{4}$.

As the result of a careful and personal examination into the merits of the questions in dispute, we now make the following, and we trust, final statement: Dr. Dawson's plates measure $5 \times 4\frac{1}{2}$ inches, and Dr. Piffard's plates measure $5\frac{1}{2} \times 4$ inches. Dr. Piffard used Dr. Dawson's cells, which were of course of same size as those used by Dr. D. Dr. P. used two more negative and positive plates than in Dr. D.'s battery, but Dr. D.'s lead and two pumps displace about as much fluid as Dr. P.'s extra zinc and platinum, and practically speaking the fluid used by each is the same. As we have said before, in regard to the merits of their batteries, we suspend judgment until after the report of the committee from the Journal Association.

How to Cure "a Cold in the Head."—Dr. David Ferrier, Assistant Physician King's College Hospital (London), recommends the use of a snuff composed as follows: Hydrochlorate of morphine, two grains; acacia powder, two drachms; trisnitrate of bismuth, six drachms. Of this powder, one-quarter to one-half may be taken as snuff in the course of twenty-four hours. The inhalations ought to be commenced as soon as the symptoms of coryza begin to show themselves, and should be used frequently at first, so as to keep the interior of the nostrils constantly well coated. Bismuth alone answers a very good purpose; but the acacia is added to give greater bulk to the powder, and to make it sufficiently light to be easily snuffed. The morphia is added in cases where it is advisable to strengthen the sedative effect. Dr. Ferrier speaks of it almost as a specific, and as being capable of aborting the "cold" in a few hours. Our friend Dr. Prout, of Brooklyn, must now look to his laurels.

Prof. Huxley was recently surprised by receiving a check for one thousand pounds from a Mr. Thomasson, of Manchester, in the name of his lately deceased father, who was a great admirer of the Professor, and highly appreciated his achievements in the furtherance of the knowledge of the science of life.

Surgical Anatomy of the Tibio-Tarsal Articulation.—Dr. John A. Wyeth, of this city, has republished, in pamphlet form, his Wood Prize Essay, from the last number of Hays' Journal.

The Medical Department of the University of Michigan is striving to extend its regular course of instruction to three years. There is every probability that in the end its plan may be successful.

Dr. Dewitt C. Peters, late Surgeon U. S. Army, died in Brooklyn, N. Y., of consumption, April 22, aged 47 years.

The Spread of the Plague.—From March 28th, to April 1st, one hundred and forty-five new cases of the plague have occurred at Bagdad, and seventy-five deaths. The disease has spread to Hillak, a town of Asiatic Turkey, sixty miles south of Bagdad, where there have been sixty-six new cases and forty-two deaths, and has also crossed to the left bank of the Tigris. Dr. Millingen, of the Turkish Sanitary Service, has been sent from Syria to the seat of the epidemic in Mesopotamia, in company with two other physicians of the service. At Bagdad a permanent Sanitary Commission has been instituted, one of the members of which is the physician of the English Consulate-General.

Statistics of Ireland.—During the quarter ending September 30th, there were registered in Ireland 5,131 marriages. During the quarter ending Dec. 31st, there were 31,960 births, equal to an annual rate of 24.1 per thousand, and 22,990 deaths, representing an annual mortality of 17.3 per thousand.

London Medical Charities.—London rejoices in the maintenance of eighty-five medical charities.

LEUCOCYTHEMIA.

BEING A PAPER READ BEFORE THE MEDICAL SOCIETY OF THE COUNTY OF NEW YORK, MARCH, 27, 1876.

By EDWARD G. JANEWAY, M.D.,

PHYSICIAN TO BELLEVUE HOSPITAL, N. Y.

PART II.

PALLOR is usually a marked symptom, though there are differences in its degree, as might readily be imagined. The pallor is due more to the diminution of the red globules than to the increase of the white. In one of my patients the pallor was not very marked for a considerable period, yet the proportion of white globules to red was large. In another, B. F., the pallor when I first saw her was much more marked than it is to-day, for the reason that she had recently had a copious hemorrhage, from which she is at present not suffering.

In the third patient there is profound pallor, yet this is the case in which the red globules are markedly diminished. I had the opportunity of contrasting this patient's blood with that of a boy suffering in all probability from pernicious anæmia. The number of red globules in the boy's case was nearly as diminished as in the man, and the pallor was nearly as great; yet the boy had no more than the normal number of white corpuscles. The pallor is perhaps more liable to be overlooked in those who are engaged in out-door occupations, where a certain amount of browning of the skin of the face deceives the observer. An examination of the lips and conjunctiva in such cases will show that a certain amount of pallor exists. I have not found it specially mentioned in a large number of the histories of leucocythæmic patients examined; yet, as I attribute this to neglect and not to the absence of this evidence, it is as well not to mention the proportion.

Pain in the left side was present, and usually as the initial symptom, in 34 cases. I have already spoken sufficiently about this symptom in earlier remarks. It may have been present in a few other cases and not have been recorded.

Weakness of a certain amount is probably present in all cases, and, as already stated, may be one of the first symptoms of which the patient complains. It may compel the patient to give up work, confine him to his bed, or only be of sufficient severity to shorten somewhat his capabilities for exertion.

As you have already heard, one of my patients was able to drive until recently.

Another is at present engaged in vending fruit on a street corner. The third is confined to his bed, and for three months at least has been unable to work.

This weakness will of course be increased by the occurrence of fever, hemorrhages, discharges; and when these cease, a certain amount of strength may be regained. As the fatal termination approaches, the debility becomes marked.

Dyspnœa of a certain amount existed in a fair proportion of cases.

This dyspnœa may be dependent in part upon some complication, as hydrothorax, bronchitis, pleurisy, the pressure of enlarged glands upon the trachea or bronchi; but it will also be present in those cases where none of these lesions exist; or, when they are present, be too great to be explained by their existence. It is not infrequently the case that the dyspnœa is much more marked subjectively than objectively, *i.e.* that the patient complains of a greater distress than he apparently suffers.

It is to be referred to the condition of the blood, which, being deficient in red globules, cannot convey the proper amount of oxygen to the tissues. The enlargement of the spleen, and also of the liver, when existing, filling as they may the greater part of the abdominal cavity, by preventing the proper descent of the diaphragm, may occasion a part of the difficulty. It is more marked upon exertion than when the patient is quiet, and is often more a desire for breathing, as one of my patients expressed it, than absolute distress.

Dropsical effusions are of quite frequent occurrence. In the slighter grade, this simply produces a little puffiness of the skin about the feet or malleoli. More excessive, it occasions marked swelling of the lower extremities. In the cases I examined, it was mentioned in nearly one-half of the number; ascites existed in one-fourth, and was of sufficient amount to call for paracentesis in two cases. The dropsical effusion may also take place in the pleural cavity or in the air-cells, and in these situations we will find that it occasionally produced death.

Diarrhœa.—This is another frequent event in the course of the disease; and we will find that occasionally, from its severity, it has brought about a fatal termination. I find it mentioned in nearly one-third of the cases, and in about one-fifth as of some severity, and repeated.

Hemorrhages.—The most frequent source of hemorrhage is the nasal mucous membrane. In one of my cases, for a time, this was an almost daily occurrence. In another it has occurred, but has been only slight in amount. It existed in the cases examined in one-fourth of the number. In some of these it was very severe, repeated, and requiring plugging of the anterior and posterior nares. Less frequent sources were, the mucous membrane of the stomach (3), the bowels (3), the gums (2), the lungs (2), from a fistula (1), subcutaneous in the axilla (1). The origin of this last is not given.

In a few cases ecchymotic spots were present on the skin. In the case stated as hemorrhage beneath the skin in the axilla, Vidal on two occasions punctured a tumor which had formed in this site, giving exit to 300 grammes at first, and to 200 grammes on the second occasion; then he made a free incision, removing 1,200 grammes, nearly three pints.

Loss of appetite is recorded in only a small number of the cases; the probability that it existed at times in other cases is great. Vomiting occurred in ten cases.

Profuse perspirations were noticed in fifteen cases. These, as in other diseases distinguished by debility, were both distressing and debilitating.

Distress from cough is noticed in sixteen cases. In some it was dependent upon bronchitis occurring as a complication; in others upon a phthisical affection of the lung; and again, probably owing to the irritation of enlarged glands producing pressure, and a consecutive bronchial catarrh.

Fever.—This is apt to happen towards the close of the cases, and may occur during the course of the disease. In a few cases it has attended its outbreak. In the third of the patients which I have observed, the temperature has been higher than natural since he came under observation.

As in other diseases with febrile movement, an ex-

acerbation is apt to occur at night. Fever was noted as taking place in seventeen cases.

Headache, due in all probability to the insufficient nutrition of nerve tissue, was observed often enough to give it a place amongst the occasional effects of the disease.

Emaciation has been noted in eighteen cases. Considering the previous symptoms, more or less wasting would seem to be a consequence that might be anticipated with greater frequency.

Difficulty of swallowing, owing to pressure of enlarged glands in the neck and thorax, was present in four cases.

Salivation occurred once. *Stomatitis* occurred once. *Palpitation*, fainting fits, vertigo, jaundice (3), were present occasionally.

Abscesses, or *boils*, were noticed three times. Frequent micturition was a marked circumstance in my patient No. 1. It was especially troublesome when he was jolted, as in riding, and I attributed it to the pressure of the large spleen on the bladder.

An anæmic murmur is present in some, thought not in all cases. It occurred in only one of the three which I examined, and it is noted in some of the histories, and not spoken of in others. A variety of retinitis accompanies this disease, and is hence called leucocythæmia or leukæmia. The urine in cases has varied, and has been more or less diminished toward the last. Uric acid has been supposed to be increased by some; not in my case, and not constantly enough to make it of value. Hypoxanthin has been found pretty constantly in the splenic variety; not, however, in the lymphatic. The existence of lactic, formic, and oxalic acids are differently given.

In the case of Patrick G., the urine had a low specific gravity, a diminished quantity, but no abnormal ingredients could be detected in it. It seems as if, owing to the impoverished state of the blood, marked diminution of tissue-change was one factor. (Examined chemically by C. Doremus.) Dr. Gordon examined the urine of patient No. 1, but could find nothing marked about it.

The most prominent feature of the disease, besides the change of the blood, is the condition of the spleen and of the lymphatic glands; and these factors together make the diagnosis in any case easy. The size attained by the spleen and the lymphatic glands will be given under the head of pathological anatomy. These parts usually slowly and gradually increase in size; sometimes, however, more rapidly. They may enlarge together or separately. The mixed variety is the most common; then the splenic, and then the glandular. How frequently the marrow is involved is, as yet, uncertain. It was not thought of until 1869.

In those cases where no sufficient enlargement of the spleen or glands can be found, the marrow should be examined.

Cause of death and mode of dying.—The causes which I could make out as producing the death were as follows:

Asthenia in 34 cases; in 21 gradually produced; in 3 owing to previous profuse diarrhœa; 1 to tuberculosis; 1 due to previous abscess and lymphangitis; 1 due to recent pleurisy, œdema of lungs being also present; 1 to pneumonia; 1 to phthisis pulmonalis; 1 to hemorrhagia from a follicular ulcer of stomach; 1 to vomiting, diarrhœa, and fever; 1 to vomiting of blood two days before death.

Asphyxia in 7 cases;—1 due to pneumonia, hydrothorax, bronchitis; 1 to œdema of the lungs; 1 to œdema and pleuritic effusion; 1 to pneumonia, œdema, and congestion; 1 to pleuritic effusion; 2 to pressure of glands.

Asphyxia and asthenia in 2 cases;—1 to ascites, hydrothorax, œdema of lungs; 1 to hydrothorax and œdema of lungs.

Apoplexy in 5 cases;—1 meningeal; 1 cerebellar and of fourth ventricle; 1 in the ventricles of the brains and outside of the dura of spinal cord; 2 several apoplexies in the brain, and in one also involving cerebellum.

Syncope in 2 cases:—Pyæmia following amputation of leg produced death in 1 case; and hemorrhage from splenotomy in two cases.

The duration of the disease it is difficult to determine. The exact origin being in many cases very indefinite, it is almost impossible to calculate even approximately in some cases the length of the disease.

I have attempted, however, to do so, and arrived at the following results in such cases as I had the means of estimating, and which had arrived at a fatal termination—though it is very possible that I have not marked the whole prodromal stage.

It seems probable that five died within 6 months after development; ten within 6 to 12 months; sixteen from 1 to 2 years; eleven from 2 to 3 years; four from 3 to 4 years; five from 4 to 5 years; one from 5 to 6 years. Mosler mentions two cases of children of eight and ten weeks. Of those which died in this city, three were under one year of age. Some attempt to divide the disease into three stages.

1. A prodromal. 2, a developed; and 3, a stage of distribution of the disease upon other organs and of pronounced cachexia.

Mosler divides it into two stages.

1. A premonitory stage, during which the disease is forming, and the blood and the affected organ are becoming involved in the leukæmic process.

2. A stage of distribution of the leukæmic process upon other organs, and of pronounced cachexia.

He divides the duration, in considering the subject, and does not attempt to give the total duration in consequence of the doubt attending the origin.

CAUSATION.

The ages of the patients whose histories I examined were as follows:

The youngest was 5 years, the oldest 70 years of age; two were under 5; two between 5–10; four between 10–15; three between 15–20; eight between 20–25; eight between 25–30; fourteen between 30–35; seven between 35–40; six between 40–45; six between 45–50; six between 50–55; two between 55–60; three between 60–70.

As regards sex fifty were males and twenty-nine females. The proportion is very nearly three-eighths females, five-eighths males.

Four males were between 40–45; two females between 40–45; four males between 45–50; two females between 45–50; two males between 50–55; four females between 50–55.

An examination of the records of death, shows that in New York the disease occurs to a limited extent.

No. of cases of death from leucocythæmia:

1867, none; 1868, none; 1869, three—two males, one female; 1870, two males; 1871, three males; 1872, seven—five males, two females; 1873, seven—four females, three males; 1874, seven—four males, three females; 1875, eight—five males, three females. Total, 37—twenty-four males, thirteen females.

Upon what ground the diagnosis was made in these cases I am unable to state.

AGES IN THESE CASES.

Years.	Males.	Females.	Years.	Males.	Females.
1	2	1	45–50	2	2
5–10	4		50–55	3	1
15–20	2	1	55–60	2	
20–25	3		60–65	1	
25–30		2	65–70		1
30–35		2			
35–40	2	1	Total,	24	13
40–45	3	2			

The youngest age at which the disease has been noticed, is mentioned by Mosler as six weeks.

The following diseases preceded the occurrence of leucocythæmia, as far as I find them of sufficient importance to record:

Abscess: Glandular of the neck, four years before; measles at outbreak; variety, splenic and glandular.

Arthritis with anchylosis: Myelogenic type; duration of fistula 16 years.

Boils: Three years before, in a case of splenic type.

Cancer ulcerating: One case of glandular variety.

Eczema of legs: One case of glandular variety.

Exposure as sailor: One splenic.

Fracture of a rib, left side: One splenic, occurred 2½ years before.

Hemorrhage: One splenic and glandular—uterine, at child-birth, also a wet dwelling; one splenic from miscarriage; one splenic epistaxis for years.

Hygiene bad: One splenic.

Lactation prolonged: One splenic and glandular; she nursed a child five years, and until two years before disease.

Malarial fever: One splenic and glandular one year before; one splenic two years before; one splenic with phthisis eight years before; one twenty years, at times; one three years before, and twenty-seven years before; one seventeen years before.

Pneumonia: one splenic three years before.

Rheumatism: Several attacks at different ages; fever of some kind two years before.

Scarlet Fever: One splenic, a few glands involved; one three years before.

Syphilis: Splenic and glandular, occurred *at outbreak* of disease; one inherited.

Typhoid Fever: One splenic disease, commenced during convalescence; one eleven years before splenic.

Painters: Three cases, none of whom had lead colic, or evidences of poisoning by lead.

Mosler ascribes one case to strong mental excitement.

In many of the cases there is nothing to which the disease can be fairly attributed, and even in some of the cases which I have presented there would naturally arise a doubt as to the connection between the disease and its predecessor. The *post hoc ergo propter hoc* method of reasoning about the causation of disease is always dangerous, and it seems to me that Mosler falls into this error especially when he ascribes it to mental excitement in one case and to syphilis in another. It is well to record these cases, and perhaps at some time they may be of value in elucidating the origin of disease; at present it is premature to consider them as causes. Mosler draws attention to the fact that his was the first recorded case of origin of leucocythæmia with syphilis. Syphilis is a very frequent complaint; and the question naturally arises, why did it in this particular case produce leucocythæmia rather than in others? This same question comes back with equal force with reference to these other assumed causes.

It is of interest that three of these should have been painters.

Mosler alludes to a case of sudden origin from injury to the side from falling off a horse; I do not think that in this case there is a certainty that the disease had not already commenced; though I admit that it was probably accelerated by this accident. He alludes to the probability that injury to bones stands in causative relationship to the myelogenic form.

The disease is mostly present in the poorer classes of the community. Ordenstein referred one case to inherited syphilis, and claimed to have produced a cure by means of liq. Van Swieten.

Pathological Anatomy.—The condition of the spleen is one of the most important factors in this disease. It is found enlarged except in cases of pure glandular or marrow type. In a number of the cases which I examined the weight was given (34). It varied from 10 oz. in a child to 14 lbs. in an adult.

Spleen weight in these cases.—Under one pound, one 10 oz. child; from one to two pounds, 9; two to three, 5; three to four, 7; four to five, 7; five to six, 3; six to seven, 1; seven to eight, 3; eight to nine, 0; nine to ten, 1; ten to eleven, 2; fourteen lbs. 1.

It is to be supposed that the size varies with the weight. But it does not do so in that exact proportion which might have been anticipated. This would imply a difference in the specific gravity. I will mention a few of these exceptions. Perhaps the size was not accurately taken. 3¾ lbs.=11 × 6 × 3½; 3 lbs. 13 oz. =10 × 6¼ × 3½; 3½ lbs.=9½ × 6½ × 4; 5 lbs. 6 oz.=12 × 7½ × 4½; 5½ lbs. =11½ × 5½ × 4; 1½ lbs.=8 × 4 × 1½=48; 1½ lbs.=8 × 4 × 2 =64; 2 lbs.=9 × 6 × 3=162; 2 lbs. 15 oz.=8½ × 5½ × 2½ =116¾.

The size of the largest mentioned was 14 inches long, 10½ broad, and 4 inches thick. The examination in these cases also showed that in enlarging it always did so most in length, then in breadth, and least in thickness. The greatest thickness was 4½ inches. The capsule was thickened in a number of cases, either granular or in patches. The consistence of the spleen was usually increased so that it was sometimes spoken of as creaking under knife, of board-like resistance, carnified, or dense and firm. In others again it was stated to be simply hyperplastic, and in a small number the consistence was diminished, and it was easily broken down under the finger, or mushy. Its color is variously described as of a brownish red, bluish red, clear red, dirty black, pale grayish red, etc. In this in a number of cases the malpighian bodies are described as appearing either somewhat enlarged or as branched follicles. In others, the texture is spoken of as uniform—or again, a number had either what might be considered as infarctions or points of inflammation. Again, in a few the surface was coated by a recent fibrinous exudation. The splenic vein, though only spoken of in some as enlarged, was probably so in all. The disease in the spleen consists of an hyperplasia of gland elements, and in some of increase of framework also.

The liver was the seat of one or two processes, either a simple hyperplasia, or else of leukæmic new formations. The enlargement did not exist in all cases, notwithstanding the marked enlargement of the spleen. It was also enlarged in some cases in which the spleen was of nominal size.

The increase in weight varied from a slight amount, as 5 lbs., 6 lbs., 7 lbs., 8 lbs., and in one case three or four times, and another, the largest, 16 lbs. (7.48 kilogrammes). Mosler gives 14 lbs. as the largest weight attained by the liver. The increased weight is due to hyperplasia. In one case cirrhosis is stated to have been present, but this was to be looked on as an inter-

current affection. In 13 of the histories of cases which I have looked over, leukæmic knots were stated to have been present.

The enlargement of the lymphatic glands takes the upper hand in other cases, as in the second which Virchow described. This enlargement may involve all the glands, or be more limited in its distribution. It may be associated with the splenic form, or be independent of it. Besides, the lymphatic glands, the other organs, as the thymus, the thyroid, the solitary glands and Peyer's patches, the tonsils, and the lymphatic gland structures at the root of tongue, may become enlarged.

The lymphatic ganglia may acquire the size of a goose-egg; many are recorded of pigeon's-egg size. These glands, besides being enlarged, are in some cases described as being semi-fluctuating in consistence; others have a little firmer feel; on section, they have appeared of pale white color, with perhaps a tinge of red; others of pale reddish-gray color.

Friedrich records a case in which lymphoid new formation took place, not only in the spleen and lymphatic glands, but also in the mucous membrane of the stomach, of the small intestines, and of the large. He described them as looking like the medullary, infiltration of typhoid fever before ulceration.

The marrow of the bones may become affected; and some look upon this affection as the primary site of this disease (*Neumann*). Waldeyer describes a very good case of this variety.

The marrow, instead of being red, as in the short bones, etc., may become yellow and almost pus-like in its appearance, as in Neumann's; or, as in Waldeyer's, be more of a hyperplastic nature. Waldeyer, in his case, was disposed to place the leukæmia to the account of the bone marrow rather than to the spleen, whose enlargement was principally of an acute nature.

The lungs, the pleura, and the kidneys have also, at times, been the seat of secondary new formation of lymphatic structures; in the latter, rather as an infiltration of lymphoid cells.

The condition of the blood was that which attracted the most attention at first, and also led to the discovery of the disease.

In marked examples of the complaint it has been more or less white, and in the heart-cavities it has sometimes appeared like pus; so that in one case, on the opening of the heart, a bystander supposed an abscess to be present. The clots, too, have a more mushy, white character than usual, and in the red there is a tinge of white.

In speaking of the causes of death, I have sufficiently alluded to other pathological states complicating the disease. I might, however, add that Bright's disease may occur.

The treatment of leucocythæmia has been in the majority of the cases without permanent benefit.

Those medicines which have been claimed as successful are particularly quinia in large doses (Mosler), phosphorus (Broadbent and Wilson Fox), liquor Van Swieten (Ordenstein, case of inherited syphilis).

Mosler records, in the article on Leukæmia in Ziemssen, a case of which he gives the details, treated by quinia.

He gave a ten-year old boy 1½ drachms in five days; 15 grs. in the first two days, then 20 grs. in the next three days; then omitted it for two days; then for the next seven days he gave him 10 grains a day, and then for eleven days 6 grains a day.

Blood showed white, red globules, 1.20 at first; later, complete recovery dating from the use of quinia. The type in this case was splenic, and he states that the enlargement of the spleen also disappeared and has not returned.

Broadbent records a case which had an increase in the number of white blood-globules, though not the number expected, considering the extreme anæmia, together with a marked enlargement of the spleen, (reaching to the umbilicus), which yielded to the use of phosphorus. He gave a phosphorus capsule, at first twice, and then three times a day.

The spleen became so much smaller that it was almost under the border of the ribs. The liver also having been enlarged, became smaller, and the color improved. He does not know the final result, as the boy after a while failed to attend. He took phosphorus nearly seven weeks, and in this time the improvement occurred.—*Practitioner*, January, 1873.

Wilson Fox records a case of cure also; he used at first $\frac{1}{100}$, and then $\frac{1}{50}$ of a grain of phosphorus.

Landois, in his work on transfusion of blood, published in 1875, was only able to gather the results obtained in four cases.

Of these four cases the following are the statements:

Blasius: 1861, *splenic*; death.

Mosler: Splenic variety; temporary bettering, later relapse, then death; amount used 6 oz. of defibrinated blood.

Huter: splenic; 225 grammes defibrinated; after five weeks repeated; temporary improvement; later, death.

Heyfelder, Roussel: 260 grammes direct; permanent success.

I have already stated that Ordenstein has claimed a cure in one case, by the use of liquor Van Swieten, the case being one with inherited syphilis as the cause.

Splenotomy has been undertaken in two cases, once each by Bryant and Köberlé, the result being death in both the cases.

In addition to these methods which I have recorded, because success has been claimed from them, iron, iodine, or iodide of iron are usually recommended. I had been told that Dr. Da Costa had placed on record a case cured by the use of hypodermic injections of ergot, but I was unable to find the journal in which such statements were made.

The prospect of treatment is not very encouraging; but in view of these recent cases of recovery under several different plans of medication, it seems more amenable than had for a long time been supposed.

I should add that since this article was placed in print the case No. 2, B. F., has presented herself for examination; her spleen has increased in size, both in length and breadth, and the proportionate number of white blood-globules has rather, if anything, increased. Her general health has, if anything, improved; her color is better, probably owing to the exposure, and probably to an increase in the absolute number of the red globules.

Case No. 3, P. G., has died. He contracted an asthenic pneumonia of the left lower lobe, which proved fatal.

I regret that an autopsy could not be obtained.

Note.—I have omitted to mention the theories regarding the method of development of the disease, preferring to do so at a future time.

British Medical Association.—For some unexplained reason, the profession at Brighton, Eng., are not much in favor of the coming meeting of the British Medical Association in that place. The recent death of the President elect, who was a representative from that city, may be seized upon as a pretext for changing the place of meeting.

DUMB-BELL PESSARIES, AND KNEE- AND BREAST POSITION.

By JAMES D. TRASK, M.D.,

ASTORIA, N. Y.

In the January No. of the *New York Medical Journal* will be found a description by Dr. R. A. Page, of Washington, D. C., of a pessary constructed of cotton batting. His description of the mode of making the instrument is as follows: —"For an instrument of the ordinary size required, take a portion of hard rubber rod, either hollow or solid, the thickness of a lead pencil and about one inch and a half long. This may be bent in any desired curve by running it through the flames of an alcohol lamp and moulding with the fingers. The rod thus prepared is laid upon a piece of cotton-batting, about ten inches long by eight wide; the long edge must be folded over about an inch and a half on each side. The rod is then placed at the short edge of the cotton, and firmly rolled the whole length of the piece, after which it is wrapped in the centre tightly with strong sewing silk, for a space of about an inch and a half, leaving a soft, compact, and elastic ball at each end. Over the wrapping I sew a piece of lint very smoothly, with the nap outside, and the pessary is complete." The cotton batting should be "about one inch in thickness."

At the time that the description of this instrument fell under my eye, I had under my care a lady who has for several years suffered from aggravated anteversion. The vagina is relaxed, and there has been extreme tenderness of the uterus. Both these have seemed to depend upon congestion following the retarded flow of blood incident to the displacement. A faithful and persevering use of appropriate means had failed entirely to relieve the patient. These included the trial of various forms of pessary usually employed for anteversion, including Dr. Thomas' modification of Dr. Cutter's pessary, and his own well-known instrument for anteversion.

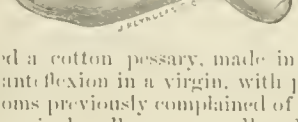
On reading the article of Dr. Page, I at once procured the materials; and, following his directions, constructed with tolerable success one of his instruments. The two extremities, however, were flattened from before backward, instead of being round like the extremities of a dumb-bell, and the whole was covered with oiled silk. After replacing the uterus, the instrument was introduced; and, to my great satisfaction, I found that it held the uterus in its proper direction in the axis of the pelvis. I directed my patient to withdraw it every night; and, after cleaning the surface, place it for a while in a solution of chloral, and lay it by to dry; and further instructed her to replace the instrument every morning by means presently to be described.

No instrument that I had before introduced could be retained more than two or three days, by reason of a sense of tenderness in sitting down, which was by that time inevitably felt in the perineum.

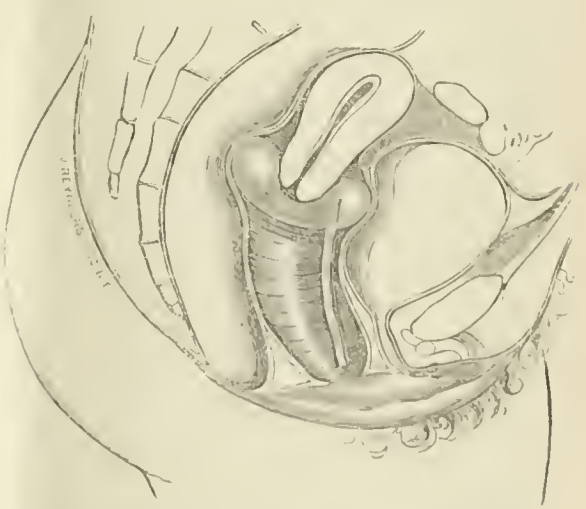
When, however, this time had elapsed, my patient experienced no discomfort; and declared that, for the first time, had she been aware of any real sense of support from a pessary, or been relieved from the distressing pain in the back incident to standing or walking. Moreover, on making examination some time after removal of the instrument, the uterus was found to have retained its proper position.

The cotton becoming soon soiled, I instructed my patient in the manner of making the pessary. Dr. Page seems to make little of the trouble involved in the making the instrument, but any one who has not become expert, will find that it requires a great deal of time. It occurred to me that an instrument could be constructed on this model, from india-rubber, and filled with air or cotton, or other elastic substance. Mr. John Reynders, 309 Fourth Avenue, taking one of cotton as a model, had one made of india-rubber, which has proved a perfect success. The instrument filled with air is very light, of course very elastic; yielding, to a certain extent, to sudden impulses as from mis steps, and withal preserving the uterus in its normal position, while it raises it from the floor of the pelvis, and thus permits an uninterrupted circulation through its blood-vessels. One of its extremities passing up into the cul de sac behind the cervix, and the other pressing upward in front of the cervix, it is equally fitted for anteversion, retroversion, or simple prolapsus.

It is evident that this instrument is employed to the best advantage in a vagina in which the anterior wall is yielding, so that the end of the pessary can pass well up in front of the cervix. If open at all to the objection brought against pessaries in general, that of distending the vagina, this action is limited mainly to its long diameter, the instrument lying in the axis of the canal, and being of a diameter too small to distend it materially in a lateral direction.



I have used a cotton pessary, made in this way, in one case of anteflexion in a virgin, with perfect relief to the symptoms previously complained of; in this case the anterior vaginal wall was unusually relaxed.



I have no idea that this form of pessary is destined to supplant all others; but as an expedient in the class of cases of which the first one referred to is an example, I am certain it will prove a most valuable acquisition to our resources. Every practitioner has at times cases in which the uterus, remaining enlarged from defective involution, is crowded down to the floor of the pelvis by the weight of the superincumbent intestines, with the bladder pressed upon by the fundus, and the cervix pushed against the rectum, or lying in the directly opposite position; with the uterus more or less œdematous from retarded circulation, and a generally relaxed state of the system from protracted ill-

health, and has had occasion to deplore the inefficiency of all instruments in common use. To such I would most heartily commend a trial of the dumb-bell pessary. It differs essentially in form, so far as my acquaintance with them extends, from all pessaries previously constructed. The term "dumb-bell" sufficiently designates it and its modifications.

In the *Atlanta Medical and Surgical Journal*, June, 1875, will be found an abstract of a paper communicated to the Georgia State Medical Society by Prof. H. F. Campbell, of Augusta, Ga., upon the treatment of uterine displacements by the knee-and-breast position. While giving full credit to Dr. Sims for making the profession acquainted with the great advantages of this position in explorations of the vagina, Dr. C. urges its great value as a means of relief in the various forms of uterine displacement. The advantages of this measure are certainly not unknown to those who are familiar with Dr. Sims' teaching and practice. Dr. Campbell, however, deserves the credit of bringing before the profession in a very clear light the benefits to be derived from this change of position, and of showing how its efficiency can be most thoroughly secured, as well as of enforcing these advantages in a manner to challenge attention. By diagrams he shows how completely, when the woman is placed upon her knees and breast, *with the thighs vertical*, the abdominal viscera fall away from the uterus, leaving it more or less completely to the influence of gravity, and causing a reduction of its displacements. On assuming the knee and chest position, the structures at the outlet of the vagina are almost invariably brought into close contact, and, acting as a valve, exclude the atmospheric air; but, instantly, upon retraction of the perineum, the atmospheric air rushes, generally audibly, into the vagina, and the canal becomes converted into an ample, dome-like cavity, and the pelvic viscera are allowed to gravitate still more readily toward the diaphragm. Dr. C. has contrived a tube of glass which he calls a "pneumatic self-repositor," which I have found extremely convenient for the purpose, with which the patient is furnished, and she is instructed as to its introduction. The great advantage of the "inverted gravity" plan consists in its affording to the patient with a dislocated uterus the means of self-replacement. Every one is familiar with the difficulties sometimes encountered by the physician in effecting reposition of a displaced uterus, with the woman in the dorsal position—his efforts resisted by the weight of the superincumbent viscera and the muscular walls of the abdomen. By the knee-and-breast position, unless there be adhesions, the patient accomplishes the reduction for herself; and, by adopting certain precautions in the manner of lying down, may preserve to a considerable degree the advantages gained, so long as she keeps quiet. The comfort derived by these patients, as well as by pregnant women, by even a few minutes' occupation of the position, is often very considerable.

The knee-and-breast position I have found of incalculable value in preparing the way for the introduction of the pessary by the patient herself. In extreme cases of anteversion it is sometimes quite impossible for the patient, unaided, herself to introduce an instrument behind the cervix. Let her, however, upon rising, while still undressed, assume the genu-pectoral position, and, reaching up, introduce the glass tube into the vagina. After remaining in this position a few minutes, or until it becomes irksome, let her quietly drop upon her left side, with her right limb drawn up as high as possible, and with the breast still inclining toward the bed. She can with the right hand, assisted more or less by the left, introduce with perfect facility a pessary, which will pass readily beyond the cervix. When the dumb-bell pessary is employed, it should, after being lubricated, be introduced with its concavity toward the coccyx, and pushed along the vagina until the anterior extremity has disappeared under the pubis, when, often spontaneously, or, at least, with slight motion imparted by the finger, the instrument will rotate on its axis, and the extremities occupy their respective positions before and behind the cervix. That the knee-and-breast position is a preliminary indispensable to their success is stated most emphatically by those patients who have attempted to introduce a pessary under the usual conditions and have failed.

From the combined employment of the knee-and-breast position and the dumb-bell pessary I cannot but confidently anticipate a greatly increased satisfaction and success in the management of hitherto intractable cases of uterine displacements.

NOTE.—A looped tape is attached to the anterior extremity of the dumb-bell pessary, to facilitate its removal by the patient.

The glass tubes are made by J. Reynders & Co.

A CASE OF PARALYSIS OF BOTH VOCAL CORDS, FOLLOWING A FALL UPON A WHEEL-BARROW.*

By BEVERLEY ROBINSON, M.D.,

ONE OF THE PHYSICIANS TO CHARITY HOSPITAL, NEW YORK; SURGEON TO THE MANHATTAN EYE AND EAR HOSPITAL, ETC., ETC.

J. B., 43 years of age, was seen by me for the first time on January 6th, 1876. Four months previously, while in the act of wheeling a load of dirt in a barrow up an inclined plane from a cellar to the street in front, he slipped and fell a distance of four feet. In his fall, his throat came into violent contact with the hind part of the barrow, and he instantly felt a sensation of cracking, and a considerable degree of localized pain.

For a few hours after his accident he expectorated every few moments small quantities of blood, bright red in color.

Twenty-four hours later he began to spit muco-pus mixed with blood. During this time his neck was swollen exteriorly; and the night of the fall my patient could not sleep on account of "the choking" occasioned by the phlegm in his throat. The dysphagia persisted, and was annoying for three or four weeks.

Little by little this symptom improved, and he now swallows as usual (Jan. 6th). There was nearly complete aphonia for 15 days. The loss of voice did not manifest itself so soon, however, as the difficulty of deglutition. In fact, until several hours had elapsed after his fall, it appears to him that he spoke tolerably well. When it did become evident, his voice was reduced to the faintest whisper. By degrees it returned. He is still slightly hoarse, and more especially in the morning, when he can scarcely make himself understood. During the day his voice acquires greater strength, and towards evening he can converse for a time, about as usual. He complains of the sensation of a lump in his throat,

* The patient was shown to the members of the New York Laryngological Society, at a stated meeting.

actually, which rises constantly, and it seems as if it would choke him should he be prevented from swallowing every few moments. Since his accident, his throat is very dry, and he is forced to drink water very frequently in order to render his life bearable. There is slight cough, which he has had from the time of his fall. Prior to this occurrence, he had always been a perfectly healthy man.

On palpation of the larynx, there is at present (Jan. 6th) no evidence of an ancient fracture. The outline of the thyroid cartilage is absolutely normal. There is no pain on moderate pressure, and the patient swallows easily. He is apparently obliged to use some effort in order to render his articulation of sounds distinct. And he states, when asked, that after prolonged conversation he feels great fatigue in the throat. If he attempts to raise his voice immoderately, it immediately becomes squeaky. He has especial difficulty in sounding clearly the very low notes, and is not able to modulate his voice in conversation.

Examination of the larynx with the aid of the laryngoscope shows some thickening of the interarytenoid commissure; congestion of the vocal cords anteriorly; left ventricular band swollen; small superficial ulcerations along the free border of the epiglottis.

In phonation, the glottis presents a decided oval in its ligamentous portion; the vocal processes and cartilaginous portion of glottis act normally.

Treatment.—Application of ferri perchlor. (℥ i.–℥ i.) to the epiglottis and the interior of the larynx.

Jan. 13th. In phonation, the right vocal cord makes a more convex outline, considered exteriorly, than the left. The left vocal cord leaves the median line more slowly than the right, while the patient inspires. Congestion persists; speaks with less difficulty; voice stronger; choking sensation not so intense. Treatment—ut supra.

Jan. 15th.—Same condition.

Treatment.—Ferri perchlor.; emplast. cantharides over larynx.

Jan. 19th.—No change. After this date I lost sight of patient, and am not familiar with his future history.

Already I have reported a somewhat similar case to the above in the MEDICAL RECORD of May 1st, 1874. The present one differs notably from it in two particulars. 1. The cause, which was a fall, not a blow. 2. The result, which was bilateral palsy of the larynx; not unilateral.

This is, so far as I know, a unique case; and for this reason, if for no other, worthy of being recorded.

Its physiological interpretation is interesting, and to me the simple and natural one appears to be nearest the truth. Both recurrent nerves were either severely contused or lacerated at the time of the accident, owing to direct compression of them by the larynx and trachea. For a complete discussion of the pathogeny of an analogous example of contusion of the larynx, in many of its features, I refer my readers to the article quoted above.

PATENT FOODS.—The *Lancet*, in a recent number, speaks against the principle of advertising patent foods, the ingredients of which are not publicly stated.

SOCIETIES FOR THE PROTECTION OF INFANT LIFE in France held a Congress on the 19th.

Progress of Medical Science.

GENERAL PROGRESSIVE PARALYSIS IN ITS RELATION TO SYPHILIS.—A posthumous paper on this subject by Dr. Jespersen has recently been published, and embodies some very interesting statistics.

The author refers briefly to the impressions prevailing among investigators concerning the syphilitic origin of paresis. Before 1857, when Esmarch and Jessen brought forward their well-known hypothesis, no one had definitely affirmed that syphilis was the cause. Several recent authors have published histories of a few cases where syphilis had been present, but, in reality, Steenberg, Kjellberg, and Sandberg are the first who investigated the question with thoroughness. The author had the opportunity of examining all that could be ascertained with regard to a syphilitic history in 123 paralytic patients treated at the St. Han's Hospital between January, 1863, and May, 1872. Among them, constitutional syphilis was found to be present in 83; chronic, in 6; "syphilis in the highest degree probable" in 6; in 13 there had been "a genital affection, gonorrhœa or the like, which might possibly indicate syphilis;" and in 15 there was nothing indicative of syphilis.

Of 59, the author could state pretty accurately how long after the acquisition of syphilis the paresis commenced; 5 to 9 years in 34; 10 to 14 in 15; 15 to 19 in 13; 20 to 28 years in 7. In a considerable number of cases he ascertained what form of syphilis had preceded the paresis. Generally they had been mild cases, and not the rarer destructive forms. The paresis usually did not become developed until after several years (at least four years) after the last symptoms of syphilis. Only in a single case did he find characteristic symptoms of syphilis occurring during the course of the paralysis; doubtful eruptions (unclean ulcers) occasionally presented themselves, however, towards the end of the patient's life. Of the whole number there were only 10 females, the remaining 113 were males, generally at the most vigorous period of life. The author finds that the prognosis is far more unfavorable in the form of paralysis than in syphilitic brain diseases. The treatment involves the use of anti-syphilitic remedies at the earliest possible period.—*Hospitals-Tidende*, No. 34.

NEW METHODS IN ESMARCH'S BLOODLESS OPERATIONS.—In a lecture by Prof. Esmarch, separately republished from Langenbeck's Archives, some new applications of the elastic bandage for bloodless operations are given. He there alludes to his successful use of this appliance, in a case of myxosarcoma of the right axilla, which necessitated removal of the whole arm, with the scapula, and outer half of the clavicle. He found the plan very efficient in preventing hemorrhage during an operation he undertook for the relief of a man, almost the whole of whose penis, with the anterior surface of the scrotum, had been destroyed by an epithelial cancer. He passed the tubing twice round the stump of the penis and root of the scrotum, crossing the ends over the pubes, and then again over the sacrum, and finally fastened them in front around the belly. Prof. Esmarch also describes two new little pieces of apparatus, devised for securing the ends of the elastic cord after the limb is encircled by it. The one is by Mr. Foulis, of Glasgow, and consists of two short pieces of brass tube, soldered together side

by side, and one of which is slit open lengthwise. Through this slit, the ends of the stretched cord are lodged in the tube, and contracting, hold each other securely. Prof. Esmarch thinks he accomplishes the same object with less injurious pressure upon the limb, by having the split tube soldered to a small, flat brass plate, instead of using the double tube of Foulis. In reply to the question how long the principal parts of the body may be kept in the bloodless condition, he says that the two lower extremities may be kept so completely for two hours and a quarter without injury.

Esmarch on the Treatment of Deep Atheromatous Cysts of the Neck.—In a lecture in Berlin, before the German Society for Surgery, Prof. Esmarch described the following as his method of treating these cysts, considering it as much safer than extirpating them. He makes a puncture, with a small hydrocele trocar, and verifies the diagnosis by microscopic examination of the fluid withdrawn.—He then proceeds to wash out the sac thoroughly by repeated injections of a one-per-cent solution of carbolic acid, until the water returns clear. Lugol's solution is now injected, and retained for a few moments, until by gentle rubbing it is brought into contact with the whole internal surface of the cyst. The sac generally soon fills again, and becomes somewhat painful; but it soon shrinks, and the cure is complete after a variable period.—The paper is accompanied by lithographs, explanatory of the cases which are given in illustration.

Nerve-Stretching in Affections of the Nervous Centres.—Some years ago Prof. Nussbaum, of Munich (*Aerzl. Intelligenzbl.*), published the history of a case of tonic spasms and pain, which arose as a sequence of a concussion of the arm. The affection was cured by the stretching of the brachial plexus. Since then, other surgeons have successfully applied the same method in different nervous affections. The professor restored by his method last year, a patient who had been suffering for nine years from a reflex epilepsy that had caused five or six convulsive attacks daily. These were announced by pain in the terminal branches of the great sciatic nerve, and ceased after the stretching of the great tibial nerve. Experiments, made afterwards with animals, have shown that a slight stretching of the nerves increases the reflex action, while a stronger stretching reduces it.

Recently, a patient whose lower extremities had been paralyzed for eleven years, applied for help. He was, besides, very much troubled with clonic spasms of the lower extremities. His deplorable state was made still worse by a paralysis of the bladder and of the rectum. The disease was caused by a fall upon the sacrum. When the patient heard of the first result obtained from the nerve-stretching, he hoped to get rid of his spasms by the same method. But, as the trouble was doubtlessly caused by an affection of the nervous centres, the professor could hardly be induced to comply with the wishes of the patient. Nevertheless he was at last persuaded to fix a day for the first operation.

Beforehand, a diluted solution of carbolic acid of the strength 1.20 was prepared. This was intended for cleansing purposes, as well as for the spray and for the moistening of compresses.

When the spray was directed towards the inguinal region, the doctor made an incision through the skin, as if he intended to tie the femoral artery near Poupart's ligament. Then he cut through the fascia, isolated the crural nerve, brought his right forefinger under it like a hook, and pulled it so strongly that the foot changed its position. He then took the nerve between his thumb and forefinger and pulled it first towards its root, and after that towards its termination. When this was done the nerve appeared somewhat prolonged. Next, he washed the wound with diluted carbolic acid, introduced a drainage tube into its lowest part and closed it with antiseptic silk. The whole inguinal region was afterwards covered by a compress moistened with diluted carbolic acid.

The patient was then placed upon his abdomen, because of a similar operation which was to be done with the great sciatic nerve. The skin was for this purpose cut between the tuber ischii and the trochanter major. After the operation was completed and the patient had regained his consciousness, he exclaimed that he felt entirely relieved of the spasms in his right extremity. The wounds healed within a fortnight, after which the nerves in the left extremity were operated upon with the same good result. But he was benefited by these operations in another way. As the spasms of his legs had ceased, he could put on mechanical instruments, and was thus enabled to walk around his room.

Continuous Aspiration in Thoracentesis.—When a large amount of pus is suddenly withdrawn from an empyemic cavity, it either soon reappears there, or there is apt to be a hemorrhage, both of these conditions being due, according to Mr. Hewitt, to the pressure being suddenly removed from the vessels in the pleural tracts. To obviate this danger the following procedure is recommended, when the ordinary trocar and canula have been used. First of all, a caoutchouc tube is to be passed through the canula into the empyemic cavity. Then the canula is to be withdrawn and the outer end of the caoutchouc tube is attached to a glass tube piercing a cork and reaching to the bottom of a vessel containing a weak solution of some antiseptic. By gently lowering and raising the bottle the cavity is cleansed, and by changing the first bottle for others the cavity is evacuated of pus and filled with the antiseptic solution. The amount of fluid in the cavity is lessened daily, by keeping the bottle at a lower level than on the previous day. By this mode of operation Mr. Hewitt thinks that pus will form less rapidly, and that there will be less danger of hemorrhage.—*British Medical Journal*, March 11, 1876.

A Case of Pica.—Dr. A. M. Gould was consulted a short time since by an unmarried lady of forty-three years, who had generally enjoyed good health. She had menstruated regularly till within a year, when there was a profuse menstrual flow, of an unnatural muddy color. She had craved unnatural food for over two years, and at the time of the visit was eating fine sand as an article of diet. She was seized with this desire by seeing some workmen putting sand upon a road. There was more or less dyspnœa, the bowels were constipated, the tongue was clean, but her appearance was that of a strong and healthy person. The heart and lungs were not examined. Laxatives and iron were prescribed. About four months after, the doctor again saw the patient, and found the appetite for the sand as strong as ever. As a substitute, two ounces of carbonate of iron, a teaspoonful three times a day, was ordered. So long as she used the iron she could refrain from the sand-eating. She said she had nearly eaten a bushel, and she baked the sand in order to destroy anything that might be injurious in it.—*The Boston Medical and Surgical Journal*, April 13, 1876.

THE AFFAIRS OF THE HEALTH OFFICE.

WE are not surprised to find at the completion of the investigation into the management of the affairs of the Health Office, that Dr. Vanderpoel has vindicated his conduct to the entire satisfaction of his friends. Despite the damaging testimony which has been brought before the Assembly Committee, we have been hopeful from the first, and expressed such a disposition in our last issue when referring to the charges. It was impossible, however, in view of a general professional feeling of anxiety upon the subject, to ignore the claims of an impartial discussion, and in that view we opened the question. The charges of maladministration, it is true, were founded upon published reports of the doings of the Committee; but as these bore on their face the evidence of authenticity, we were forced to notice them in the presentation of one side of the argument. As we have done so in the performance of an unwelcome duty, we the more gladly seize the opportunity of presenting the other side.

As far as we can understand, the investigation took its origin from a desire to find out what were the fees of the Health Officer for the past two years, with the view of deciding upon the advisability of abolishing said fees and making the office a salaried one. For this purpose, the following resolution was passed by the Assembly:

"*Resolved*, That the Committee on Commerce and Navigation be directed to ascertain what the fees and revenues of the Health Officer of the port of New York were in 1874 and 1875, respectively; and that for this purpose they be authorized to send for persons and papers and summon witnesses, and to employ a stenographer to take the testimony."

Under this resolution, Dr. Vanderpoel was called before the Committee. Although there was nothing in the resolution looking towards any charge against the conduct of the Health Officer, the investigation drifted so far from its legitimate purpose, that his personal integrity was directly assailed.

It appears from the testimony before the Committee, that irregularities in the administration of the affairs of the office did really exist, but that Dr. Vanderpoel was wholly ignorant of them, and that they occurred against his express wishes. Although the actual facts, when sifted from the sensational element which at present belongs to official inquiries of this sort, show the irregularities to be of a comparatively trivial character, the Health Officer, in view of the responsibilities of his office, and on a question of principle, will be held more or less accountable for their existence. The worst, however, that can be said of him is, that he was not so watchful as he might have been. There is now, however, no question that his intentions were beyond reproach, which is the best possible vindication of his character for integrity.

After these few general statements in regard to the present aspect of the affair, we are prepared to examine the testimony in connection with certain specific charges. The chief complaint made was, that Dr. Vanderpoel had ten per cent. of the charge made for repairing the State boat at Fletcher, Harrison & Co.'s taken off, and applied to the bill for the repairs made by the same firm to the doctor's private boat. The facts of the case, as brought out in the testimony, are simply these: — When Dr. Vanderpoel bought the "Gertrude," it was almost worn out. He went to his friend Mr. Van Santvoord, who for many years had been engaged in steamboat building, and asked him to have the necessary repairs made. The work was done by Fletcher, Harrison & Co., whom Mr. Van Santvoord had, on numerous occasions, employed for work of his own. The bill was sent to Mr. Van Santvoord. The amount being so great, and being in fear that the repairs would exceed the worth of the boat, he, without the knowledge of Dr. Vanderpoel, and as a friendly act to him, asked for a deduction of ten per cent. This was agreed to, as a matter of business with Mr. Van Santvoord, and the bill was accordingly rendered to him; when Dr. Vanderpoel for the first time knew of the amount, and paid it accordingly. This deduction was not made on behalf of any repairs made on the State boat, nor was the bill for the repairs on the State boat made any greater thereby.

The charge that small repairs of the doctor's private boat were smuggled into the repair bills for the State boats is explained by the fact that such smuggling was due to a subordinate, who approved said bills as being correct, and which Dr. Vanderpoel believed to be correct. The doctor unqualifiedly swears that he never knew nor suspected any irregularity in the proceeding, and his testimony is not contradicted. During all this time he was paying bills for repairs from his private purse. In regard to the money obtained by the sale of "junk," it is shown to have been paid out

entirely for State property, under the authority of the old board of Quarantine Commissioners.

As to the "Gertrude's" services to the State and the many damaging aspersions made against the doctor's management of its financial affairs, it is clearly proven that the said boat was hired by the State after the burning of the "Fletcher," for twenty dollars per day, the State agreeing to find the coal and men for running her. It does not appear from the evidence that any of the State coal was used when she was not in service, or any charge made for any time she was lying idle. On the contrary, whenever she performed any accidental service for the State, such as in the case of the "Numancia," quarantined during 1872, in the Lower Bay, she delivered her earnings to the Comptroller, which in that case amounted to over sixteen hundred dollars, the only personal fees collected being those which legitimately belonged to the Health Office.

From an examination of the evidence before the Committee, we fail to see anything irregular in the practice of delivering foreign newspapers at the quarantine ferry slip. This was merely a matter of accommodation for the public, and without any direct or indirect expense to the State.

Concerning the appropriation of State labor and State property to private uses, there is a reasonable explanation. Whenever the boat was used for private purposes all its expenses were paid by its owner, but when employed officially in the State's service, State coal was burned. It seems, however, that some of the State property, in the shape of waste and oil, was used on the vessel without the same being properly accounted for. This, however, was one of the trivial matters already referred to, with which the subordinates were entrusted, and concerning which the Doctor had no immediate knowledge. The "hands" in State employ were never asked to perform service on the "Gertrude" unless said hands were for the time being off duty. Obviously this was not interfering with State interests.

It will not serve our purpose to follow the testimony in any farther detail, except to state in a general way concerning the principal and important charges that one and all are absolutely without any foundation in fact; and, far from proving Dr. Vanderpoel unworthy of his trust, the manner of their refutation is his best recommendation.

We have devoted some space to the consideration of this matter, not only on account of justice to the Health Officer as a gentleman whose integrity we never doubted, but as a matter of principle in vindicating the honor of a profession of which he has long been an acceptable member.

THE MINIMUM AGE OF PUBLIC SCHOOL ATTENDANCE.

Any one who is accustomed to visit the different public schools of this city will be struck with the crowded condition of the primary departments. This is in the main due to the custom, principally among the Germans, of sending children to school at the earliest possible age allowed by law. The parents of these infants seem to look upon the primaries more as nurseries than schools; for in no other way can the number of children between the ages of four and six be accounted for. It is preposterous to suppose that these little ones can learn anything except to sit still, sing the alphabet, and become proficient in the calisthenic drill. To the impossibility of any beneficial mental development at this age, is added the evil effects of confinement, bad ventilation, over-taxation of the nervous system, and all its attendant evils; when, on the contrary, every means should be employed, and every freedom allowed, to aid the development of the physical forces. Not only is this system of crowding these children of tender age into the class-rooms positively detrimental to themselves, but relatively injurious to the older ones, who are better able to receive instruction and more capable of intellectual development. In the present crowded condition of the schools there is no room for these infants; and not only for this, but for other reasons equally apparent, we take occasion to endorse most heartily the effort being made to prevent, by legal enactment, the admission of any child below the age of six years. There is every argument in favor of the enactment of such a law, and none against it—except, perhaps, to make the minimum age seven years. Let not only this provision become a law, but let there be an amendment to it, to the effect that all the children of the primary departments be dismissed for the day at noon. The medical profession has long been agreed concerning the advisability of such measures, and the Board of Education and the Legislature are sure of its active sympathy in their laudable efforts towards reform.

Dr. H. B. Sands, President, in the Chair.

DISCUSSION ON LEUCOCYTHÆMIA.

The paper on Leucocythæmia, read by Dr. E. G. Janeway, being open for discussion,

Dr. Fordyce Barker remarked that he thought its author had hardly done Dr. Hughes Bennett justice, while commenting upon the relation which he sustained to the discovery of this disease. Dr. Barker was of the opinion that, inasmuch as Dr. Bennett announced that there was no antecedent phlebitis or purulent collection in any part of the body of his patient, he was entitled to the priority in the discovery of a disease not before described. Dr. Barker then directed attention to the question of diagnosis, and asked, "Shall it be made by studying the relative

proportion existing between the red and white blood-corpuscles, or, shall it be made by studying all the symptoms which are associated with the development of the disease?" He then discussed the question as follows: First, with regard to the relative proportion existing between the red and white blood-corpuscles. Is it not a fact that microscopists agree that science is not yet able to distinguish between a white blood-corpuscle, a pus corpuscle, and a mucus corpuscle?

Science has not yet reached the point at which her aid can be invoked, either through the microscope or other means, for a successful determination of the question, whether this relative proportion is an absolute increase of white blood-corpuscles or pus corpuscles, hence the use of the term leucocytes, which applies to these three kinds of cells. Now then, I think that there are certain cases, for instance of pyæmia, where the same microscopical appearances of the blood can be found, and the general symptoms are in most respects similar to those which have been described this evening, but which, under some circumstances, are curable. If memory serves me right, the normal proportion of leucocytes in the blood is about 1 to 350 or 400 red blood-corpuscles. Pathologists, I believe, have agreed that the term leucocythæmia is not to be applied to any case unless the ratio between the red and white elements in the blood is changed to such a degree that the leucocytes are found in the proportion of 1 to 20 red corpuscles.

Now, I have seen cases where leucocytes have been present in the blood in the proportion of 1 to 12, 1 to 14, 1 to 8, etc., and the patients subsequently have made a good recovery. The question may now be asked, Were these cases of leucocythæmia? My answer is, that they were not; but I regarded them as cases of pyæmic infection. The question then next arises, is it an essential feature of the disease, that this ratio, or vastly increased proportion of white to red blood-globules must be associated with splenic, or hepatic, or glandular enlargement, or disease of the marrow of the bones? If that be necessary, we have no right to make a diagnosis of leucocythæmia from a microscopical examination of the blood alone; but we must have associated with the increased relative proportion of white blood corpuscles, of leucocytes, splenic hypertrophy, glandular changes, hepatic enlargement, or disease of the marrow.

But at this point in our inquiry we meet with another difficulty; for we have to settle the question whether the blood change is the primary essential element of the disease, or whether it is simply the result of other essential lesions; just as dropsy is a result of a primary lesion of the heart, kidneys, or liver? That question is not yet settled. If we assume that all the cases of leucocythæmia are the result of certain essential splenic or glandular or hepatic disease, or disease of the marrow of the bones, then we have a new difficulty of diagnosis—the fact that all those symptoms which are found to characterize true leucocythæmia exist in certain cases with the entire absence of any evidence whatever of splenic, hepatic, glandular, or marrow disease.

I remember very distinctly a paper by M. Boufilo, published some twelve or fifteen years ago, in which he reported cases which had all the characteristic phenomena of leucocythæmia, such as the dyscrasia, the pallor, the asthenia, and finally death, without any evidence of glandular, hepatic, or splenic changes. Since that time, other cases of like character have been published. In Hays' Journal, a few years ago, Dr. Horatio C. Wood published a paper upon what he terms "Pseudo-leucocythæmia."

All will agree as to the importance of a correct diagnosis between a disease which has thus far proved to be beyond the resources of any remedial treatment, and another disease which may closely resemble it in its attendant phenomena. I would not say that the symptoms are precisely the same; for I think a careful study of the two diseases will show some characteristic differences. For example, I think pyæmia always causes rapid emaciation, while in leucocythæmia there is anæmia and asthenia, but not necessarily emaciation. I saw in 1862 a lady from Philadelphia, who had leucocythæmia of the typical glandular form. A few weeks after, I saw her again at Newport with Dr. King, of that city, the day before she died of asthenia. But, in her case, there was no emaciation, for although she was very pallid, she was a fine specimen of *embonpoint*. There was also no appearance of emaciation in the case of a gentleman in this city, who died of glandular leucocythæmia, although he had repeated attacks of hemorrhage from the nasal passages and also from the bowels. Again, I think there is a marked difference between the thermometric phenomena of leucocythæmia and pyæmia. The fever of leucocythæmia is only manifest in the advanced stage of the disease; it is a hectic, and the thermometer I have never seen indicate a rise of more than two or three degrees above the normal standard. Now, in pyæmia, the fever is a constant phenomena, with marked variations during the day, often from four to six or more degrees.

Dr. Barker then briefly described some cases of pyæmia which he had seen, in which the blood-changes, as to the proportion of the white to the red corpuscles, was as great as in typical leucocythæmia, and most of the general symptoms were similar to those of leucocythæmia. One was the case of a young lady in Hartford, whom he saw two or three years since, in consultation with an able and accomplished physician of that place. Before his visit to Hartford, microscopic examinations of the blood had demonstrated such an enormous increase in the proportion of the white to the red corpuscles as to convince this gentleman that it was a case of leucocythæmia. But the absence of all evidence of splenic or glandular enlargement, the character of the attendant fever, the extreme emaciation and the antecedent history of the case, led Dr. Barker to regard it as pyæmia. Some time previously she had pelvic cellulitis, which terminated in abscess with recurrent purulent discharges into the rectum. The patient died a few weeks after he saw her; and, strange to say, the result of an autopsy confirmed her physician in his opinion as to the nature of the case, while it equally convinced Dr. Barker as to the correctness of his own diagnosis. He then alluded to other cases which had come under his own observation, in which the blood-changes and the general symptoms would seem to warrant the diagnosis of leucocythæmia, but who had eventually recovered their health. One was that of a lady whose history was very much the same as that just mentioned. Another was that of a young man who had several times had suppurative tonsillitis. He had the blood-changes and many of the symptoms of leucocythæmia, as entire loss of appetite, great prostration, a feeble heart-action, hemorrhages, and recurrent diarrhœa, from which he would rally by the use of very large doses of quinine and alcoholic stimulants. The tonsils were honeycombed with small abscesses, from which pus could be made to exude from numerous little openings by pressure.

He perfectly recovered his health after the tonsils were excised by Dr. Morell Mackenzie, of London.

In conclusion, Dr. Barker added that he who will clearly demonstrate the differential diagnosis between the one disease, which, so far as we know at present, is incurable, and the other, from which patients do sometimes recover, will render an important service to medicine as an art, and to humanity.

Dr. Heitzmann referred to a case of leucocythæmia which came to his notice, where the patient sought relief for stone in the bladder. He had had several attacks of malarial fever; his spleen was much enlarged, and his blood contained a large proportion of white blood-corpuscles. Diagnosis was uncertain before any operation was performed. The stone, however, was removed by the lateral operation; and shortly after the wound began to bleed, and a fatal hemorrhage ensued, the patient dying within two and a half hours.

Dr. Heitzmann also referred to the fact that hemorrhages not infrequently occurred, which were altogether out of proportion to the size or depth of wound made upon the bodies of pregnant women, and that, undoubtedly, there was in such cases an excess of white blood-corpuscles.

The doctor further remarked that it was impossible to decide where the disease came from, for the reason that we did not know from whence the white blood-corpuscles were derived.

Dr. Heitzmann disagreed with Dr. Barker's statement that mucous corpuscles were not distinguishable from white blood-corpuscles; for, by means of high powers, he believed the microscopist was able to recognize the fact that the mucous corpuscles were much more finely granular, and had a distinct internal structure which could be easily demonstrated. He agreed, however, with Dr. Barker in the belief that we did not have means of discriminating between pyæmia and leucocythæmia by a simple microscopical examination of the blood.

Dr. Janeway remarked that in examining the blood there was a great liability to mistake the swollen red blood-globules for white blood-globules, especially by those unaccustomed to making such examinations. The crenated appearance of the red blood-globules produced by evaporation might be easily mistaken for white blood-globules. He called attention to the fact, also, that increase of white blood-globules was a feature of leucocytosis, or symptomatic leucocythæmia; and yet the patient did not have true leucocythæmia. Increase of white blood-corpuscles might be found in connection with many chronic diseases, such as cancer, phthisis, malarial fever, etc. On the other hand, however, patients might have malarial fever or cirrhosis with enlarged spleen without having a marked increase of white blood-corpuscles, one of the leading features of leucocythæmia.

He further remarked that, with regard to diagnosis, the existence of splenic and glandular enlargements and the entire absence of blood-changes, was one of the difficult features of leucocythæmia and pseudo-leucocythæmia which at present remained to be explained.

The doctor also regarded it as possible that the deep-seated glands might be enlarged, while the superficial ones remained unchanged, and yet recovery take place. In that instance, the cases would be placed under the head of non-enlargement of the glands.

Dr. Janeway also restricted the term pyæmia to those cases in which, from thrombosis and embolism, secondary abscesses were developed in organs distant from the seat of the primary injury. Those cases which presented very much the same phenomena as seen in pyæmia, but in which there were no secondary abscesses, were placed under the head of septicæmia. In accordance with that view, he did not regard Dr. Barker's cases as pyæmic. The doctor was also of the opinion that the glandular hyperplasia, which goes with pyæmia, uterine disease, etc., might explain the increase of white blood-corpuscles in those cases.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, April 12, 1876.

Dr. Chas. K. Briddon, President, in the Chair.

CHONDRO SARCOMA OF FEMUR.

Dr. E. Mason presented a specimen of tumor of the thigh which he had removed by operation from a widow, a patient of Roosevelt Hospital, aged 35 years. She presented a delicate appearance, and her family history was that of phthisis. Five years before admission, she suffered from pain along the outer aspect of the left thigh, from the hip to the knee. The pain increased, and after subjecting herself in turn to the sulphur and water-cure treatment, it abated somewhat. Five months ago she first noticed a small tumor in the front part of the left thigh just below the groin. At first the growth was soft and painless, subsequently enlarging with rapidity; it became hard and tender, and became the focus of a pain extending to the hip and down the thigh. On admission, a tumor was discovered on the antero-lateral aspect of the thigh, two and a half inches before the anterior superior spinous process, extending internally as far as the median line, and backward as far as the great trochanter. Vertically it measured 3½ inches, and transversely 5¼ inches. The circumference of the thigh over the tumor was 20¼ inches, and over corresponding portion of opposite thigh 18½ inches. The Sartorius muscle and femoral artery skirted over its inner margin. It was hard to the feel, its margins ill-defined, and it was apparently connected with the bone. The skin was not adherent. There was no enlargement of the inguinal or lumbar glands, and no growth was detected in the pelvis. Rotation of the thigh caused considerable pain, as well as any stooping posture which she might assume. The operation was performed March 27. A simple straight incision exposed the surface of the tumor, which presented a shining appearance. It was situated directly below the capsule of the joint, and was evidently connected with the bone. All around the margin of the growth there were distinct spiculæ of bone. After the tumor had been superficially disconnected, an attempt was made to detach it from the bone: but on so doing the sac ruptured, discharging a bluish starchy material. What remained of the tumor was then removed; the bone surface and the spiculæ were cut away with a chisel. The whole surface of the exposed bone was scraped, and preparations were made to close the wound. At this time, however, it was noticed that, in a depression of the bone, there was exuding some of the same kind of starchy material already noticed, evidently from the deeper parts below. In the attempt to scoop out this material, the necessary turning of the instrument caused it to drop into a cavity in the bone, disclosing a soft pulsating mass of diseased tissue. It was the opinion of the consultation that immediate amputation at the hip-joint was necessitated, but the consent of the patient not having been previously obtained, that operation was not performed. The wound was then closed up. For several days the

patient did badly, but at the time of making the report her condition had much improved.

Dr. DELAFIELD, to whom the tumor had been given for microscopic examination, reported that the sac was composed merely of connective tissue and spiculæ of bone. The gelatinous substance adhering to the inner wall of the sac was composed of basement membrane, partly fibrillated, partly granular, and partly hyaline, in which was imbedded round fusiform and stellate cells, which resembled those of hyaline cartilage. It seemed to be a tumor composed of cartilage tissue, with an excess of cells, a considerable admixture of ordinary connective tissue cells, and belonged to the class called chondro sarcoma. In regard to the prognosis of these tumors, he remarked that it was very uncertain, some had never returned, and others had made their reappearance with great rapidity. Although in that particular instance the prognosis was bad enough, the case was nevertheless not absolutely hopeless.

A SYMPTOM OF BONY TUMOR.

Dr. MASON remarked that there was one feature in this case which, in his opinion, had an important chemical bearing, he having noticed the same symptom in similar tumors connected with the bone. This symptom was a pain, deep seated and severe, which ante-dated the appearance of the tumor for years.

MORBUS COXARIUS—EXSECTION, ETC.

Dr. MASON presented a second specimen, consisting of the head and trochanter of the femur, removed by operation from a boy, twelve years old, likewise a patient of Roosevelt Hospital. The patient enjoyed excellent health until two years ago, when he began to show symptoms of morbus coxarius. As far as could be ascertained he had never received any injury. When admitted to the hospital, the thigh was flexed upon the pelvis, and the leg upon the thigh; the limb was adducted, and, together with the existence of numerous sinuses in the neighborhood of the joint, showed that the disease had passed to the third stage. Dead bone being detected through one of the sinuses, exsection was advised and performed accordingly.

The disease of the femur was found located at the neck of the femur and just at the margin of the head of the bone. The cartilaginous portion of the head was intact, and the ligamentum teres was uninvolved. The deeper portion of the acetabulum was extensively diseased, but it had not advanced to perforation.

The point of interest was the seat of the disease in the neck of the bone and the interior of the head of the latter. The question was, did the disease originate in the acetabulum?

PUERPERAL FEVER, INFLECTION FROM OVARY THROUGH RETRO-PERITONEAL GLANDS.

Dr. MARY PUTNAM JACOBI presented a specimen of uterus removed from a negro woman who died in the hospital from puerperal fever. She was in a ward in which there never had been any case of puerperal fever. Two days before her death, and four days after her confinement, a woman had died in the hospital thirty six hours after confinement, of advanced disease of the kidneys. This case was mentioned, in order to explain to a certain extent why no anxiety was manifested about this case until just before death. Within thirty six hours after her confinement, when there had been no previous disease in that ward, she was seized with fever, which gave a temperature of 104 F. in the evening, but which went down to 101 the following morning. It then settled to 103 in the evening for four or five days; and until the fifth day she had no evening rise. During this time she never complained of any pain; in fact there was no other symptom except the moderate degree of fever.

The night before she died she got up and appears to have lain on the floor ten hours. The next morning, six hours after the occurrence, she was seized with a violent chill, followed by fever, from which she died in twelve hours.

At the autopsy there was a great quantity of flakes of pus lying over the great omentum. The peritoneal vessels were injected, but the intestines were not agglutinated. Half a pint of liquid pus was found in the cavity of the pelvis, but there was no exudation over the peritoneal surface of the uterus, neither was there any evidence of inflammation of that organ. This was the only interesting point—the left ovary was covered with a purulent exudation; and notwithstanding it had been for a long time immersed in hardening fluid, it was, compared with its annexa likewise treated, almost disintegrated. The Fallopian tube was filled with puriform liquid up to the opening in the uterus, but not beyond it. The internal surface of the uterus was healthy. A chain of retro-peritoneal glands, extending from the pelvis very nearly to the diaphragm, were enlarged and covered with pus, seeming to point to a direct infection from the inflammation of the left ovary. The interpretation of the case was, that the first fever, lasting a few hours, was connected with inflammation of the left Fallopian tube; that it proceeded by continuity to the left ovary; after that, the inflammation was arrested, and coincidently with that arrest the fever fell; but the retro-peritoneal glands were slowly infected; thus constituting the channel by which the blood was poisoned.

STRICTURE OF SMALL INTESTINE.

Dr. SATTERTHWAITE presented a specimen of stricture of small intestine taken from an Irishman aged fifty years, a patient of Dr. Hadden. The patient was taken sick in February last with some bladder trouble. In the course of the treatment, Dr. Hadden's attention was directed to a strangulated hernia. This was reduced without any special trouble, but immediately afterwards the patient was seized with peritonitis in the course of two days, after which he died.

The autopsy, which was made by Dr. Hadden, revealed general peritonitis. At the point where the hernia had been reduced the intestine was hardened, inflamed and congested, and marked the situation of the stricture. In fact, three strictures were discovered at this point. The lower one was twelve inches above the ileo cæcal valve, about three inches above this another, and three and a half inches a third. The middle one was very tight, not admitting the little finger. Between them the intestine was deeply congested, and in some places the mucous membrane seemed to be eroded.

THE PLAGUE in Mesopotamia is increasing. At Hillah, from April 1 to 7, inclusive, 114 persons were attacked with the disease, and 56 died. On April 8, there were 22 attacks and 13 deaths, and on April 9, 31 attacks and 11 deaths. At Bagdad, from April 2 to 8, inclusive, there were 256 attacks and 169 deaths; on April 9, 74 attacks and 13 deaths, and on April 10, 56 attacks and 26 deaths. The highest number of cases registered in any single day was on April 9. Cases have occurred in the military hospitals and garrisons.

Correspondence.

MEXICO AS A RESIDENCE FOR INVALIDS.

Letters from Prof. E. R. PEASLEE, M.D.

III.

City of Mexico, *March* 14, 1876.

Mr. Editor:—In order not to trespass too far on the space of the Record, I now close what I have to say from this point of observation with some very miscellaneous remarks. So far as the habits of the people of the Mexican basin, respecting food, are concerned, I have nothing to remark; except that the Indian population (descendants of the Aztecs) live and labor hard upon a surprisingly small amount, and this consisting in great part of fruits not regarded as containing much nutriment. They seldom take meat, but, instead, use beans, and Indian-corn ground upon stones by the women and made into tortillas, without any admixture of lard, butter, or salt. But of a particular drink, used by almost every one in the Mexican basin, I should speak more at length. This favorite beverage is called pulque (pronounced pool'kay); and it is found that a pint a day at least is used, on the average, by every man, woman, and child in the city of Mexico; amounting, for a population of not over 250,000, to more than 31,000 gallons a day. Special trains, laden with pulque alone, are sent daily to the city, and it is brought in from all other parts not reached by railroad, in carts, or on the backs of mules. It is seen everywhere, it is everywhere smelt, and is everywhere being drunk, though the lower classes alone are seen to drink it by the tourist, as he traverses the streets; the educated class, however, drinking it equally at home. The single railroad terminating in Mexico receives $900 a day for the transportation of this liquor, the greater part of it being produced within 50 miles of the city. There are immense estates (haciendas) which produce nothing but pulque, and this is found always to be a lucrative business. This drink is the fermented juice of the maguey-plant, as it is here called—the Agave Americana, or century-plant.—a species of cactus. It has the appearance of milk, with the taste of sour buttermilk; and to which another very disagreeable taste is added, and a smell still more disagreeable, owing to the fact that it is, to a great extent, transported in hog-skins. Very evidently one must learn to like it. A quart is sold for from 3 to 5 cents, and this amount is not seldom swallowed by the drinker within 5 to 15 minutes. Used in great excess, pulque produces intoxication; and a distinguished Mexican judge remarked that the greater number of crimes implying violence, in this part of the country, are committed under its influence. On the other hand, it is generally regarded as quite nutritious, and seems much to resemble whey in this respect. Pulque is produced in the following manner: The maguey-plants are set 10 feet apart, in rows 20 feet apart, and require 6 to 7 (sometimes even 15) years to attain to the required maturity; when they are 4 or 5 feet high, and of the same diameter, as measured across their long, thick, and very succulent leaves; which radiate in all directions from the bulb or stump, 12 to 18 inches above the ground. They are 40 or more in number, and a single leaf has been found to weigh 160 pounds. When the plant begins to shoot up a flower-stalk, the latter is cut off, and a cavity is scooped out of the stump below, holding one to four quarts, according to the size of the plant. The juice exuding into this receptacle is collected daily by means of a pipette on a large scale, which takes it up by suction and transfers it to the vessel receiving it. The inside of the cavity is then lightly scraped, to excite further escape of the fluid; and thus being constantly increased, it often finally becomes larger than the largest bucket. This treatment exhausts the plant in six to seven months, during which time it may have yielded 8 oz. to even 2 quarts daily, or an aggregate, sometimes, of 100 to 200 gallons. Some have stated the possible amount to be 400 gallons for a single plant. The juice, thus collected in vessels or in hog-skins, is either retained in the latter or poured into a tank, and in 48 hours or less fermentation is completed, and the pulque is ready for the drinker. It can, however, be kept but seven or eight days, when another change occurs, rendering it useless; hence it cannot be exported from the Mexican basin. It is sent to the city, to a great extent, in the hog-skins, but partly also in casks.

The skins are prepared as follows: An incision through the skin is made around the hog's neck and around each leg, when it is everted at the neck and stripped off whole, and wrong side out. It is then *re*-turned, and the hair removed by the action of lime, and the openings, except that at the neck, tightly tied up. Finally, it is blown up, tied at the neck, and allowed to become slightly stiff and dry, and is then ready for use. The same skin may be used over and over again for five or six months, when another hog is put in requisition. At one of the pulque stations I saw an Indian untie the string around one of the fore-legs of a skin filled with this fluid, and imbibe to his satisfaction, when he tied it up again and went his way. Of the many bystanders, none made any objection to this procedure; and it is not improbable that each of the party proposed, as he should be moved, to take his turn at one of the now closed openings of the porker's hide.

From the number and the intensity of the compliments paid, on the shortest acquaintance, by the Mexican people, they might be regarded as the politest in the world. The manner in which they put themselves, their houses, and all they possess (babies, even, included), at your service and your disposal, would entirely confound an Anglo-Saxon, did he not know that all this really means nothing. Inquire respecting one's health, and he replies, "Very well, at your service," (para servir á Usted). How did he pass the night? "In your service." You take leave of him, and he assures you that "he and his house, poor as it is, are at your service and disposal."

I take the following illustration, *apropos* to babies, from the interesting journal of a two years' residence in Mexico by Madam Calderon de la Barca. She had been greatly tried in a search for a chamber-maid, which finally proved successful, when she received a note from the Senora de ——, who begged to inform her that she (Senora de ——) had another servant at Madame C.'s disposal (otra criada á mi disposicion). Madam C. replied that she was greatly obliged, but had just hired all she needed. At this the porter opened his great stupid eyes into a slight expression of wonder. But fortunately, as he was leaving, she inquired after the Senora's health, and was told that "she and the baby were coming on very well;" when it first occurred to her that it is Mexican etiquette in this way to inform the friends of the family, of the birth of a child.

Another example from Madame Calderon de la B.

illustrates the politeness of our professional brethren in Mexico to their patients; though only those of rank can expect all that follows. I give her own language.

"I have passed nearly a week in a slight fever; shivering and hot. I was attended by a doctor of the country, who seems the most harmless creature imaginable. Every day he felt my pulse and gave me some little innocent mixture. But what he especially gave me was a lesson in polite conversation. Every day we had the following dialogue as he rose to take leave:

"Madam!" (this by the bed-side), "I am at your service."

"Many thanks, sir."

"Madam" (this at the foot of the bed), "know me for your most humble servant."

"Good morning, sir."

"Madam!" (now he stopped beside a table), I kiss your feet."

"Sir, I kiss your hand."

"Madam" (this near the door), "my poor house, and all in it; myself, though useless; all I have, is yours."

"Many thanks, sir."

He turns round and opens the door, again turning round as he does so.

"Adieu, madam; your servant."

"Adieu, sir."

He goes out, partly re-opens the door, and puts in his head:

"Good morning, madam."

Madam Calderon also gives an instance in which a French gentleman took advantage of the politeness of a Mexican, and carried home a fine saddle, which the latter included in the usual expression that all he had was at the other's service.

There is one more peculiarity of these people which I should not omit to mention. If you express admiration of a horse or carriage, or any article of personal property, it is a common thing for the owner, not only to say that it is at your service, but to send it and insist that you shall accept it. And if so, a refusal would be regarded as an affront. A distinguished physician at Vera Cruz informed me that, happening to speak in laudatory tones of a horse belonging to one of his patients, he was the next day surprised to find that the owner had sent him the horse, begging him to accept it. He did not wish to give offence by declining to do so, but has since been more chary of his commendation of the effects of others.

The city just mentioned, Vera Cruz, generally regarded as the most pestilential city in America, is certainly one of the cleanest, so far as its streets are concerned, and might probably be rendered comparatively healthy if the wall surrounding it was removed, to allow of complete ventilation of the lower stories of the houses; and if an improved style of water-closets could be introduced. I am assured that there are not a dozen in the city which in New York would be tolerated. The common statement that the first "norther" of the season here both stops the yellow fever, and kills all who are down with it, is but half true. It does not kill, but rather benefits the already existing cases. Moreover, the epidemic of last season, said to have destroyed 95 per cent. of all the cases, actually proved fatal in but 55 per cent. Twenty-five per cent. is the usual mortality.

I remain, para servir á Usted,

E. R. Peaslee.

P. S.—On my return from Mexico to Vera Cruz, the train was stopped at Orizaba by the report that the *pronunciamentiados* had broken the railroad at the Bridge of Atoyac, 30 miles below. But the government forces dispersed the marauders and repaired the road, so that we were only detained till the next day. The $25,000 demanded of the government was not paid.

E. R. Peaslee.

THE FLESH SHOWER IN KENTUCKY.

To the Editor of The Medical Record.

So much speculation has been aroused by the press of the country in regard to the recent "meat shower" in Kentucky, that I think your readers might be interested in the result of my investigation of a piece of the substance sent to Prof. Chandler, of this city.

In color it was a light pinkish red, and of rather dense texture. The piece measured about ten lines in length, and about four in breadth. Beneath the microscope, Dr. J. W. S. Arnold and I found it to be lung-tissue. We saw bronchii and blood-vessels, air cells, etc; and, from their appearance, Dr. Arnold considered it a piece of the lung of a child, or, perhaps, that of a horse—the microscopical appearance of which resembles the young human lung. The question now remains to be answered by some ingenious meteorologist—How did the babies become comminuted and distributed over the fields of Kentucky?

Allan McLane Hamilton, M.D.

New York, April, 1876.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department of the United States Army, from April 23d to April 29th, 1876.

Alexander, R., Surgeon. In addition to his present duties as post surgeon, Fort Vancouver, assigned to duty as Acting Medical Director and Attending Surgeon at these Headquarters. S. O. 43, Dept. of the Columbia, April 8, 1876.

King, Wm. H., Asst. Surgeon. Granted leave of absence for one month on surgeon's certificate of disability, with permission to leave the Dept. of the South. S. O. 79, A. G. O., April 20, 1876.

Crampton, L. W., Asst. Surgeon. Assigned to duty at Vicksburg, Miss. S. O. 77, Dept. of the Gulf, April 20, 1876.

New Mode of Obtaining Local Anæsthesia.—"M. Latamendi has found that when Richardson's apparatus is used, rubefaction and a sensation of cold is produced. If at this moment a slight incision of about half an inch is made with a curved bistoury, not deeper than the epidermis and the upper layer of the cutis, from the incised spot an anæmic zone is formed which goes on spreading. If the ether spray is continued, the region becomes bloodless, and complete anæsthesia has been obtained. The knife cuts the part like butter, the spot resembling coagulated fat. Around this an annular patch is observed, which is not so completely anæmic as the centre. The spray directed upon this renders it also completely anæsthetic. Thus the anæmia can be extended in every direction, around and up the arm. If the spray be suspended, the effects disappear quickly; but the spray being resumed, in a few seconds the ischæmia returns."—*Lancet.*

Medical Items and News.

Contagious Diseases.—Comparative statement of cases of Contagious Disease reported to the Sanitary Bureau, Health Department, for the two weeks ending April 29, 1876.

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-Spinal Meningitis.	Measles.	Diphtheria.	Small-pox.
April 22d.....	0	12	80	4	51	76	16
April 29th.....	0	5	96	6	73	85	33

Puerperal Fever.—Dr. J. Braxton Hicks, in the *British Medical Journal* of April 8, reiterates his views on this subject, which he thinks is not understood as yet, nor will be until many groups of cases have been carefully studied in all parts of the world and under all possible conditions. At present the sum of our knowledge may be stated as follows: "There are many factors in the disease, all tending to the disturbance of the blood in the highly susceptible puerperal condition; each separately, or two or three combinedly, may bring about such a deterioration of the system as is evidenced by the symptoms which we have hitherto called puerperal fever."

Balard.—The well-known French chemist, who died on March 31, at the advanced age of 74 years, was Professor at the College of France, and obtained a world-wide reputation as the discoverer of bromine.

Professor Schroeder, the gynecologist, has been installed in his new professorship in Berlin, as the successor of Martin.

Medical Works in Germany.—791 medical works were published in Germany in 1875; 607 in 1874.

An Imperial Sanitary Bureau is soon to be organized in Germany. Pettenkofer, Virchow, and Hirsch are expected to take an active part in its management.

The Pathological Institute in Vienna is to receive a new life under Professor Heschl, the successor of Rokitansky. The annual sum of 2400 florins has been designated for this special department. In addition, 3,600 florins is to be given for a library, and two appointments of demonstrators are to be made, each with an annual recompense of 200 florins. Further, a sum of money is to be given for microscopes. In the course of the summer the foundation of the new building will be laid.

Death of Traube.—The medical world is called upon again to mourn the loss of another of its great instructors. On April 11, Professor Louis Traube died of pericarditis, after a long and painful illness. By Americans who have prosecuted their studies in Berlin, he will be long remembered as one of the greatest clinical teachers of Berlin, and one of the chief attractions in that medical centre. His name will be forever linked with those who have brought physical diagnosis and rational therapy to its present standard of excellence.

The Portrait of Vesalius.—It is said that the portrait of Vesalius has been discovered in the Louvre. It is by Jean de Calcar. One of the rings on his left hand bears the three letters: A. V. B. (Andreas Vesalius Bruxellensis).

M. Vleminckx, whose death was recently noticed, is supposed to have died of pulmonary embolism, the result, perhaps, of ulcerative endocarditis.

American Veterinary College.—This is the title of an institution which is now in the third year of its existence, and is, under the circumstances, in a very prosperous condition. The Faculty is as follows: A. Liautard, M.D., V.S., Professor of Comparative Anatomy, Operative Surgery and Clinical Surgery; A. Large, M.D., M.R.C.V.S.L., Professor of Theory and Practice and Clinical Medicine; A. W. Stein, M.D., Professor of Comparative Physiology; S. R. Percy, M.D., Professor of Materia Medica and Therapeutics; J. L. Robertson, M.D., V.S., Professor of Cattle Pathology and Obstetrics, and Clinical Medicine; F. D. Weisse, M.D., Lecturer on Surgical Pathology; F. Le Roy Satterlee, M.D., Lecturer on Chemistry; L. T. Bell, D.V.S., Lecturer on Veterinary Pharmacy; C. W. Crowley, D.V.S., Prosector of Anatomy; C. H. Peabody, Curator. A hospital is attached to the institution, which gives the students ample opportunities for clinical instruction. The requirements for graduation are: Twenty-one years of age; a certificate of three years study of medicine—attendance on two full courses of medical lectures—the last being in this college—a good English education, proper testimonials of character and a satisfactory written, oral, and practical examination in each department of instruction.

Cases of Scurvy in the British Mercantile Marine continue to be reported. The cause is not attributed to any failure of the supply of lime juice, but to a general impoverished condition of the system, which invited the disease, and which was due to a scanty and non-variable diet.

Legislation Against Quack Medicines.—A proposal has recently been made in London to compel every vender of a patent medicine to declare the ingredients of which it is made before offering the same for sale.

Medical Society of New Jersey.—The next annual meeting of the Medical Society of New Jersey, will be held in Congress Hall, at Cape May City, on the 23d and 24th of May, 1876, commencing at 7.30 o'clock P.M. on Tuesday. Orders for excursion tickets over the Pennsylvania Railroad may be obtained on application to the Recording Secretary. Free passes will be given over the railroad from Camden to Cape May. The train will leave Camden at 3.30 o'clock P.M. on Tuesday.

Wm. Pierson, Jr.,
Recording Secretary.

Orange, April 29, 1876.

PHYSIOLOGY OF MICTURITION.

BY ALEX. W. STEIN, M.D.,

PROF. PHYSIOLOGY AND VISCERAL ANATOMY, NEW YORK COLLEGE OF DENTISTRY, ATTENDING SURGEON, VENEREAL DIVISION, TO CHARITY HOSPITAL, ETC.

We are still in need of considerable light as to the normal enervation of the bladder, and to the physiology of micturition. That the bladder is capable, on the one hand, of completely emptying itself, though it contains but a few drops; and on the other, that it will retain a large quantity of urine without overflow, indicates the admirable influence of its nerves in regulating its action; but it is difficult to account for the many physiological phenomena which this organ presents,—why, for example, a healthy man is often unable to pass water when required to do so in the presence of a stranger who watches him; or why the first attempts of a novice to make water while in a moving wagon is often attended with difficulty, while it is easy enough for one who is accustomed to it. Nor is it altogether easy to comprehend the diverse and often obscure nervous manifestations presented by the disordered bladder. Why some patients cannot approach a running stream of water without having an irresistible desire to micturate; or why—as in a case now under observation—the patient can allow the accumulation of a definite quantity of urine unconsciously, and then be driven suddenly and by an uncontrollable impulse to evacuate the same, often wetting himself before he can get ready to obey the command. Nor can we satisfactorily answer the many pathological conundrums which cases of incontinence of urine present.

The elucidation of the physiology of the bladder, upon the just appreciation of which the knowledge of its pathological manifestations depends, involves the consideration of two questions: 1st, the arrangement of its muscular fibres; and 2d, the derivation and distribution of its nerves. We must admit that the answers to these interrogations are not perfectly conclusive or satisfactory. Yet certain developments have been made in this direction which deserve more universal recognition; and to these I invite your consideration.

The muscular fibres of the bladder are more feebly developed than those of the hollow viscera generally, and are probably intermediate in strength to those of the stomach and œsophagus. The density and development of these fibres varies, however, in different individuals and in different states of the bladder. In the young, *ceteris paribus*, they are stronger than in the old, and in the female than in the male. In the contracted state of the bladder the fasciculi appear dense, while in the state of distention they are thin and separated according to the degree of distention.

In regard to the arrangement of these fibres, anatomists are at variance; and this statement is equivalent to the one that our knowledge upon this subject is still imperfect and unreliable. For, when men of equal ability, pursuing like investigations, and employing the same means, arrive at different results, it is fair to assume that we have yet to arrive at the absolute truth. To unravel the intricate arrangement of the muscular fibres of the bladder is an undertaking of difficulty; those who have undertaken this task are well prepared to make allowances for the discrepancy of authors upon this subject.

Without entering into a detailed analysis of the views of individual writers, we may state in general terms, that the muscular fibres are usually described as consisting of three sets; an external layer having a longitudinal direction, "Musculæ detrusor urinæ," an internal reticular and an intermediate circular or transverse stratum; the latter, according to some, being especially reinforced or developed at the neck. But the dissections given us by J. Bell Pettigrew, F.R.C.S., seem to show that this description, the one usually given, is not in strict accordance with the facts. According to this eminent authority, the muscular fibres of the bladder, with few exceptions, form figure-of-eight loops, the loops embracing the urachus and urethra respectively. His observations are based upon some sixty dissections, many of which have been photographed, and appear in his memoir on this subject. Some of these beautiful preparations I had the pleasure of examining in the Museum of the Royal College of Surgeons, London, where they are permanently mounted and preserved. Pettigrew recognizes the existence of seven sets of loops, three external, three internal, and a fourth an intermediate or central. The first and seventh strata (the most external and the most internal) pursue a vertical direction, and are feebly developed; the second and sixth run in a slightly oblique spiral direction, crossing at acute angles, after the manner of an attenuated figure-of-eight, and consist of stronger fibres; the third and fifth sets are still more developed, and run in a more oblique spiral direction than the latter, crossing at obtuse angles as in a figure-of-eight flattened from above or expanded laterally. The fibres of the fourth or central layer pursue a very oblique spiral course, and crossing at very obtuse angles, form figure-of-eight loops, so flattened as to have hitherto been mistaken for complete circular fibres. While speaking of the above fibres as consisting of layers, the term layer is used in a restricted sense, the fibres rarely occupying the same plane or run exactly parallel. They moreover split up and become fused with each other, with corresponding or homologous fibres, and with fibres which are either superimposed or underly them.

The existence of a true sphincter to the bladder has repeatedly been denied, probably because the fibres of which the sphincter is composed are not separate elements belonging exclusively to the neck, but are continuous with those encompassing the body of the bladder.

Sir H. Thompson says: "It is evident that both the circular and longitudinal muscular fibres at the situation just indicated (at the neck), exist in much larger quantities than in any other part of the bladder; but their arrangement is not sphincteric. They are no doubt chiefly concerned in the expulsive function of the bladder; and their aggregation here is the necessary result, as far as the longitudinal fibres are concerned, of their convergence to one point." Budge has also endeavored to show that the circular fibres at the orifice of the bladder do not possess the function usually ascribed to them, and attributes the sphincteric power wholly to the passive contraction of the constrictor urethræ and bulbo-cavernosus muscles. In support of this view, he affirms, that if a canula is inserted into the ureter, and a column of water sufficient to overcome the resistance of the sphincter is made to flow in an uninterrupted stream from the bladder, and while the flow is going on, different parts of the bladder and urethra are faradized, it will be found that, as soon as the electrodes are applied to the con-

strictor urethræ and bulbo-cavernosus muscles, or to the former alone, the flow is instantly checked. When the electrodes are directed to the prostatic portion of the urethra, a similar, though more feeble result obtains; and this action becomes less intense the nearer the stimulation is applied to the bladder, while any part of the viscus itself may be excited, even its neck, without causing an interruption in the current, but rather an increase in the flow. With all respect to the eminent authority quoted, it seems to me that this experiment, apparently so conclusive, is not free from several objections. That the striated constrictor urethræ and bulbo-cavernosus muscles, when excited, exert a greater power of resistance to the evacuation of the bladder than do the more feeble involuntary fibres surrounding the neck and prostatic urethra, is a fact, which common observation may teach, but which thus demonstrated by experiment, still fails to prove that these muscles are the only, or indeed the essential factors in the sphincteric action. That faradization at the neck, *behind the prostate*, should have increased rather than interrupted the flow from the bladder, is a result which may be accounted for in the fact that the fibres of the bladder are common to both the neck and body of the organ; and it is not difficult to understand how artifical stimulation applied *behind the prostate*, and therefore beyond the actual seat of the sphincter, should so induce the vermicular contraction of the rest of the organ as to produce an expulsive effort. The continuity of the fibres of the neck, with those of the body, which is apparent in the preparations of Pettigrew, does not, in any way, militate against the possibility of a separate sphincter power of the fibres surrounding the neck; for, as he justly says, as well might we argue against the existence of a sphincter in the stomach or rectum, where, as is well known, there is continuity of structure. That portion of the figure-of-eight loops which embraces the urethra constitute the vesical sphincter. The fourth, or central layer of very oblique fibres, which embrace the lower two-thirds of the bladder, and upper portion of the cervix posteriorly, enter principally into the formation of the sphincter, which, together with the oblique fibres, constitute a well-developed anterior and posterior lip, while the less-developed, slightly oblique, and longitudinal set of fibres form the right and left lateral lip of the sphincter.

In reviewing this subject, we must not ignore the part which may be taken by the prostate in this function. As but a small portion of this organ is glandular, the propriety of calling this body a gland may be questioned; the secreting follicles which make up one-fourth, or possibly one-third of its mass, are, as the other glands of the urethra, but appendages of the mucous membrane, extending into the surrounding tissue. This organ is, in truth, essentially an involuntary muscle surrounding the intra-pelvic portion of the urethra, consisting of circularly or spirally arranged fibres, which are continuous with those of the bladder behind. Pettigrew says: "The external or longitudinal, slightly oblique, oblique, and very oblique spiral fibres, which form the three outer, and the central or circular tunic of the bladder and urethra, are curiously enough repeated in the prostate of the male, and the analogous structure in the female; so that this gland would seem to be composed chiefly of fibrous offsets from the longitudinal, slightly oblique, oblique, and very oblique, or circular fibres in question."

While the muscular element of the prostate possesses the undoubted function of pressing the seminal fluid into the grasp of the constrictor urethræ and ejaculator semines, does it not possess, independently of this, the other function of maintaining the closure of the vesical orifice? This view would be supported by the fact, that in the female there is a corresponding development of muscular fibres surrounding the intra-pelvic portion of the urethra. Profs. Ellis, Guthrie, Leuckhart, Virchow, and others, have distinctly recognized a rudimentary prostate in the female. Indeed, this portion of the male canal differs from that of the female only in the greater development of its muscular fibres, in connection with a special function, and in being provided with a special set of secreting glands.

Appreciating the influence exercised by the intrinsic involuntary muscular fibres which surround the vesical orifice and intra-pelvic urethra, we must give due importance to the action of the extrinsic voluntary constrictor urethræ, bulbo-cavernosus and levatores prostatæ muscles, whose natural tonicity tend, during the intervals of micturition, to approximate closely the urethral walls; and which, under the influence of volition, relax or contract, as may be necessary, for the retention, or complete expulsion of urine. The action of the levator prostatæ is especially interesting in connection with the physiology of micturition, constituting, as it does, an important factor in maintaining the closure of the vesical orifice. This muscle, descending from its origin near the pubic symphisis, passes beneath the prostate and neck of the bladder, and unites with its fellow of the opposite side, in the central point of the perineum. These fibres support the prostate and neck of the bladder as in a muscular sling, and in virtue of their tonicity, maintain the uvula against the walls of the vesical orifice. Looking through an opening made in the upper part of the bladder, a slight elevation—the uvula—will usually be seen at the apex of the trigone, projecting, as it were, into the orifice of the urethra. To this elevation has been ascribed the important function of completely closing the urethral orifice.

But we must not forget that the occasional absence of the uvula is not attended with any impairment in the integrity of the vesical orifice; while on the other hand, the uvula is not the only elevation found in this vicinity; on the contrary, there are, as first shown by Barkow, of Breslau, generally five small eminences at this point—three posterior and two anterior to the vesical orifice. Occasionally they are all absent, or else they are unequally developed in different subjects, now one and then another being most prominent. The influence of the levator prostatæ as a sphincter to the bladder, is distinctly felt, when the levator ani (of which the levator prostatæ is a part) is brought into action in the expulsive effort of defecation. While this muscle acts in raising the rectum in the expulsion of the fæces, its anterior portion—the levator prostatæ—contracts simultaneously around the neck of the bladder in a sphincter-like manner; so that, if the flow of urine has commenced, it becomes arrested with the expulsive effort of defecation. The simultaneous expulsion of fæces and urine becomes therefore an impossibility.

The tonicity or passive contraction of voluntary sphincters depends, as is well known, upon their nervous connection with the spinal cord, but it remains to be demonstrated that the involuntary sphincters do not in part derive their tonicity from the same source. In the instance of the vesical sphincter it has been shown that, after section of the cord at a certain point, the tone of the sphincter is lost; the pressure necessary to overcome its resistance being no greater than that required in the dead animal. According to Kupressow, a column of water, sixteen to twenty inches in height, is required to overcome the resistance of

the sphincter in the rabbit, which, after section of the cord, falls to five or six inches. Giannuzzi and Naurocki found that in a bitch, a column of water, thirty inches in height, was required; which pressure, after section of the vesical nerves, fell to eight inches, and was no less after death.

But, while the outlet of the bladder is thus placed under the excito-motor influence of the cord, the act of micturition can be promoted or restrained by voluntary effort. This is manifest in the ordinary act of micturition, the first step of which requires a *voluntary* relaxation of the muscles about the vesical orifice. While on the other hand, we are capable of suddenly arresting the flow of urine before complete evacuation has taken place, should occasion require us to do so. Again, we know, to our discomfort, that circumstances oblige us sometimes to defer the act of micturition, though the bladder may be in a state of over-distention.

Up to a certain point of distention, the tone of the sphincter suffices to counteract the expulsive force of the detrusor, without the intervention of conciousness or will; but when this degree of distention is exceeded, or the stimulating quality of the urine is through some cause increased, we are capable, and indeed are sometimes obliged, to reinforce the excito-motor reflexion by voluntary effort.

Appreciating the function of the perineal muscles, we find that the act of micturition requires the simultaneous activity of two forces. First, a complete relaxation of the above-mentioned muscles; and secondly, a contraction of the vesical walls, supplemented to a greater or lesser degree by the expulsive power of the diaphragm and abdominal muscles. The first action is effected in obedience to the will; the second, involuntarily, unless the diaphragm and abdominal muscles are brought into requisition in the expulsive effort. When the bladder is in a moderate state of distention, the sphincter and urethral muscles being relaxed—we believe, contrary to the views sometimes expressed, that the inherent power of the bladder is sufficient to empty its contents, independent of any extra vesical force; but if the stimulus to the so-called detrusor is insufficient to overcome the reflex contraction of the sphincter, as when there is but a small quantity of urine in the bladder, and we desire to evacuate the same without a natural call to do so, the abdominal muscles and diaphragm are brought into requisition as voluntary auxiliaries; or, when the bladder has been in a state of distention, and its walls have become stretched, it again requires the co-operation of the abdominal muscles and diaphragm to expel its contents. In the forcible expulsion of urine, the abdominal muscles act as they do in forcible expiration, but the ascent of the diaphragm being prevented by the expansion of the lungs, the force is exerted upon the contents of the abdominal cavity, and the sphincters of the œsophagus and rectum being closed, the viscera press downwards upon the bladder, expelling its contents.

There are two kinds of nerves which preside over the functions of the bladder: those which act independently of the will, but under its control, viz. the sacral plexus of the cerebro spinal system; and those which are not only independent of, but beyond, the influence of volition, viz. the hypogastric plexus of the sympathetic system. The former are traced more directly to the neck and base of the bladder; the latter distributed chiefly to its sides and upper part.

That the spinal cord is not a single nervous centre, but rather a series of centres united in a continuous column, is a statement reconcilable with what is known concerning the physiology of the cord. The researches of Budge, Kupressow, and others—experimenting independently upon rabbits, dogs, etc., demonstrate the existence of a well-defined genito-spinal centre for the bladder, and limit the same—the former to a region corresponding to the fourth, the latter to between the fifth and sixth lumbar vertebræ. Section of the cord at these points always destroys the reflectory tone of the sphincters, causing incontinence of urine, while section above the fourth lumbar vertebræ has no such effect. Budge has also shown that, besides this excito-motor centre, there is a higher regulating ganglion for the bladder, situated along the peduncles of the cerebrum and restiform bodies. Faradizing different parts of the encephalon he found these the only portions of the brain which responded to the physiological effects of electrical stimulation in exciting visible movements in the viscus. The nerves originating from these parts pass along the anterior column of the cord, and emerge with the third, fourth, and fifth sacral nerves. Some of these nerves animate the levator prostatæ, constrictor urethræ and bulbo-cavernosus, while other portions of the same proceed with the sympathetic filaments to the prostate and vesical sphincter. It is also necessary to assume that a large proportion of cerebro-spinal filaments communicate and intermingle with sympathetic nerves, to be distributed solely to the body of the organ.

When there is but a small quantity of urine in the bladder, the sensory impression communicated to the spinal cord is reflected by motor impulse to the sphincter, whose energy increases with the accumulation of urine; but, when the bladder becomes distended, or the stimulating quality of the urine is from some cause increased, the impression is no longer simply reflected from the spinal cord, but transmitted to the sensorium, where it gives rise to uneasiness or pain, and from whence is reflected that impulse which endows us with the power of voluntary retention or emission of urine. In all cases, the impression made must be powerful enough to reach the seat of common sensation; for the sympathetic is itself insensible, and its sensibility of parts supplied by it depends upon the intimate connection with the cerebro-spinal centre. Whether such impression is conducted directly from the sympathetic nerve to the cerebro-spinal centre; or whether it is first conducted to the sympathetic ganglia and thence by fibres originating in the gangliomic cells, is quite uncertain. If the former be true, the reason why the presence of a small quantity of urine does not produce an impression, may be because the number of cerebro-spinal filaments in sympathetic nerves are so few; if the latter view be correct, our insensibility to the small quantity of urine must depend on the diffusion or exhaustion of the sensory impression at the ganglion. It is generally believed that, although the sympathetic system is never the path of the voluntary motorial impulse, the influence which it exerts on the movements of parts to which it is distributed, is in great part derived from the cerebro-spinal centre, for experimentation shows that movements similar to those having their origin in the sympathetic ganglia may be produced by irritating those spinal nerves with which the sympathetic nerves supplying any given part are connected. It has also been shown that stimulation of certain parts of the brain excites movements in organs of vegetative life. We may infer, then, that if we are unconscious of movements in the body of the bladder, because so largely provided with sympathetic fibres, the spinal nerves connected therewith have nevertheless a prominent share in the movements produced. We have but to recall the

effects produced upon the bladder and other viscera by certain ideas—simple or emotional—to appreciate how closely these two great nerve-centres are associated.

In arresting the flow of urine during its passage along the urethra, we realize that the muscles surrounding the canal respond, in this respect, to the mandates of the will as promptly and as effectually as do other voluntary muscles; but when we desire to empty the bladder we become conscious of the occurrence of a distinct interval between the transmission of the volitional impulse and the flow of urine, especially is this felt when we hurriedly attempt to empty a full bladder. This is but one of the phenomena which constantly present themselves in evidence of the highly complicated manner in which the bladder fulfils its function, and which justifies the inference that there exists for this organ, in addition to the nervous centres mentioned, a special ganglion, which operates in regulating, restraining, or co-ordinating its movements. Such an inhibitory centre has been distinctly recognized; and the experiments of Goltz on dogs seems to locate it in the spinal cord, and as low down as the lumbar region.

Whatever influence this ganglion may have in bringing about an orderly sequence in the physiology of micturition, we must bear in mind, relative to the contraction of the bladder, that the cerebro-spinal nerves connected with sympathetic ganglia do not so rapidly transmit nerve force as when they have no such relation to the ganglion. And, therefore, the occurrence of the interval mentioned is perhaps not so much due to the tardy relaxation of the urethral muscles as to the sluggish action of the vesical nerves upon the walls of the bladder.

But while we are at present disposed to attribute so much of the influence of the sympathetic to its connection with the cerebro-spinal centre, we must not under-estimate its independent action upon the bladder until we know more of the physiology of the sympathetic as a whole. The presence of sympathetic ganglia in the walls of the bladder (as in other hollow viscera) is an interesting anatomical fact; and although these ganglia have hitherto been shown to have a special relation to the vascular supply, a more intimate knowledge of them may reveal important evidence bearing on the movements of the organ. Among those who have pointed out the existence of numerous sympathetic ganglia in the bladder of different animals and man, are the names of Remak, Beale, Hess, Meissner, A. Henocque, Klein, and Francis Darwin. The latter has contributed an able article upon this subject in the *London Quarterly Journal of Microscopical Science*, April, 1874.

CASE OF HYSTERIA IN A LYING-IN WOMAN, SIMULATING PULMONARY EMBOLISM.

By FRANK P. FOSTER, M.D.,

NEW YORK.

Grave lesions occurring during the puerperal period have in several instances been mistaken for hysteria. Dr. R. M. West* records a "case of sudden apoplectiform seizure, terminating fatally in thirty-six hours, on the sixth day of lying-in," in which the symptoms were at first attributed to hysteria, but in which the autopsy showed the presence of brain-lesions. Dr. Barker† gives a case of puerperal embolism of the posterior tibial, in which a surgeon, who saw the patient in consultation, was disposed to regard the phenomena as due to hysteria. In the following case, the symptoms seemed to me at first to point to the occurrence of pulmonary embolism, but they were soon found to be caused by hysteria.

Mrs. D., 25 years old, rather tall and slender, somewhat anæmic, and, as subsequently ascertained, of neurotic tendency, was delivered of her first child August 22, 1875, by a short and easy labor, concerning which there was nothing noteworthy except that there was a placenta succenturiata. For the first nine days after delivery her condition was in every respect satisfactory. The temperature in the axilla was at no time above 99.5° F. She ate and slept well, and appeared cheerful and free from discomforts, but on one or two occasions I fancied, from the expression of her face, that she was making an effort to control a tendency to some emotional outbreak. During these nine days there was some diminution in the frequency of urination, and some hesitancy in the act. She would hold her water until the desire to pass it became urgent, when she would feel an impediment for a minute or so, after which the flow would become free and full.

August 31.—I was hastily called to see her about midday. Her condition had continued favorable up to 11.30 A.M., at which time a vaginal injection was given, she herself holding the nozzle of the syringe. While taking the injection she suddenly felt a sensation as if the point of the syringe had come in contact with some sensitive part, and, instantly, pain, with a feeling of indescribable distress, spread over the greater portion of her body—now involving one part and now another. There was a sense of prostration and of impending suffocation. There was a marked chill, but it was brief and not severe. The lips were cyanosed. The lower limbs, up to the middle of the thighs, were quite cold. A slight discharge of blood took place from the vagina. Some of these facts I learned on my arrival, and others of them subsequently. I found her in a state of great anxiety, although evidently trying to control her apprehensions. She lay propped up in bed, with a number of pillows under her head and shoulders, and on any attempt being made to lower her head she complained of increased suffering. There was no true dyspnœa at that time, although the movements of the chest wall were painful, as were also those of any part of her person. That she had suffered, however, from a suffocative sensation (as distinguished from mere painful breathing) I satisfied myself by repeated cross-questioning. Her lips were still noticeably cyanosed, but I was assured that the discoloration had previously been much more decided. Her face wore the expression of great fright. The pulse was 140, and the respiration 32. The pupils were moderately dilated. The general surface was decidedly warm and perspiring copiously. Palpation of the abdomen revealed nothing abnormal, except that the stomach was rather distended with gas. The breathing was thoracic and, but for its rapidity, in every way normal. On auscultation, nothing unnatural was detected either in the lungs or in the heart. The pulse was not specially weakened. No urine had been passed since early in the morning, and there was no repletion of the bladder. The bowels had been moved by an enema the previous evening.

The only subjective symptom now was pain—constant, but varying in severity, and with surprising rapidity, in situation. It had invaded all parts of her body in turn, but was now chiefly referred to the hypochondriac regions. She would suddenly exclaim

* Trans. Obs. Soc. of London, vol. ii., 1860, p. 276.
† The Puerperal Diseases. New York, 1874, p. 259.

that she was suffering severe pain at the lower portion of the right side of the chest, and then in a few minutes she would tell me that the pain had entirely ceased in that situation, and shifted to the opposite side, and so on, in like manner, with other parts of the body; the pain flying from one arm to the other, from the right to the left side of the neck, etc. When the pain affected either arm (which did not occur during my presence) she was unable for the time being to use the affected limb; but whether this was owing to actual or supposed loss of power, or to mere dread of increasing the pain, I could not ascertain.

In view of the more striking of the foregoing facts, my first impression was that I had to deal with a case of embolism of the pulmonary artery. I soon succeeded in quieting the patient's fears, and gave her ten minims of tincture of digitalis, with a teaspoonful of brandy in a little hot water. The nurse had already given her brandy twice (about a fluid ounce in all), had rubbed her limbs, and had applied sinapisms to the chest, abdomen, and limbs. Her distress was soon mitigated, but she was still unwilling to have her head lowered, and from time to time fresh attacks of pain took place in various parts about the chest and neck. At the end of an hour her pulse had fallen to 128; the cyanosis had disappeared, and there had been no recurrence of dyspnœa. Meanwhile, the erratic character of the pain had led me to think that the case might, after all, be a mere hysterical paroxysm, and I expressed that opinion to the patient's mother. I now left her, after giving her another draught containing ten minims of tincture of digitalis and four minims of Magendie's solution, and directing the nurse to give another similar draught, with brandy, in case of a return of dyspnœa.

I saw her again at 4 P.M., when the pulse had again risen to 140; the breathing remained at 32, and the temperature in the axilla was 101·7° F. A fresh access of pain, without dyspnœa, had occurred at 3 o'clock, and the nurse had given the draught, which was soon followed by a mitigation of the pain. She was now as comfortable as when I had left her, but perspiring freely and feeling rather thirsty. There was some twitching of the facial muscles. I directed the bed coverings to be made lighter, and allowed her to drink sparingly of lemonade. Ordered

℞ Sol. morphiæ sulph. (Magendie)... ♏xxiv.
Tinct. digitalis..... ♏xxx.
Aquæ..... ʒi.
M. S. A teaspoonful every second hour.

Directed the nurse to save any urine which the patient might pass.

I was still of the opinion that the case was an hysterical paroxysm, but, reflecting that in several instances embolism had been mistaken for hysteria, and that, in genuine cases of pulmonary embolism, a temporary mitigation of the urgent symptoms had sometimes been noticed, and not having been able at that time to get a frank history of the patient's hysterical antecedents, I asked for a consultation, and it was arranged that my friend Dr. Weir should be asked to see the case with me in the evening.

Dr. Weir saw her with me at 9 P.M. She had taken two doses of the morphine and digitalis mixture, and was feeling decidedly more comfortable, being now able to lie at full length. The copious sweating was very much moderated. She was still rather thirsty, and had no desire for food, having taken none since her breakfast except a cup of beef-tea in the evening. Her pulse was 120, and the temperature in the axilla 100,3° F. The muscular twitching had subsided. She had felt inclined to sleep at times, but had resisted the inclination from the fear, as she said, that during sleep a recurrence of the symptoms might take place. A thorough examination of the chest and abdomen by Dr. Weir revealed nothing abnormal. During our visit she voided rather more than a pint of urine, of normal appearance, which, on examination with heat and nitric acid, showed no albumen, or, at all events, only such a mere trace as might well have been occasioned by a slight admixture of the vaginal discharge. The secretion of milk remained unaffected.

Dr. Weir made an unobserved diagnosis of hysteria, and recommended a cathartic, advising also that she should soon be allowed to sit up. Ordered two compound rhubarb pills, followed in the morning by a third, if necessary; ten grains of bromide of potassium to be given in case of fresh outbreak of pain, etc. Beef-tea to be given occasionally.

September 1, 9 A.M.—Pulse 88, resp. 16, temp. in axilla 99° F. Has had a comfortable night, with a fair amount of sleep. The breasts have been drawn once (the child being fed with cow's milk, to avoid its being affected by the digitalis). The three pills have had no effect. To take two tablespoonfuls of mist. rhei et sodæ every third hour until the bowels move, child to be put to the breast again, omit vaginal injections. During my visit the patient's mother had a well-marked hysterical convulsion, and I then learned that both she and her daughter had frequently suffered from hysteria.

8 P.M.—Pulse 80, temp. in axilla 98.6° F. Patient feeling better, one free movement of the bowels has occurred; still little or no appetite.

September 2.—As she had a restless and uncomfortable night, with sensations of faintness and a return of the pain in the chest and neck, I was called to see her early this morning. On my arrival she had been got on to a lounge, and had asked to be taken into her drawing-room, a proceeding which, with my decided approval, was at once carried out. I directed eight grains of quinine to be given at once.

She took some solid food during the day, and in the evening I found her in an arm-chair, feeling, to use her own words, "wonderfully better." Her recovery was uninterrupted from this time on.

THE TREATMENT OF DIPHTHERIA BY INJECTIONS PER RECTUM.

By W. H. VAIL, M.D.,

CORNWALL-ON-HUDSON.

Mrs. G——, having lost a young son in New Jersey last October, with renal dropsy, the sequel of an attack of diphtheria, came here in December to visit her sister, bringing a fur cap which her little boy had worn during his sickness. This cap her sister's little daughter M——, aged one year and ten months, wore the day before Christmas. Between Christmas and New Year's M—— was dull and listless, though not sick abed. January 3d I was called in, and pronounced it a case of diphtheria. A day or two after, Mrs. C—— called and spent some time in the sick-room, contrary to my instructions. The next week her little girl had diphtheria, and died.

It is to the treatment of M——, the medium between the other two cases, and the only one which it fell to my lot to have the charge of, that I wish to call the attention of the profession. On Monday, January 3d, recognizing the symptoms as those of true malignant diphtheria, though as yet no membrane was

visible in the fauces, I immediately began to consider, in the first place, the best means of maintaining our little patient's strength: and next, if possible, to limit the spreading of the membrane. To maintain the strength I prescribed cinco-quinine, iron, cream and milk. To limit the spreading of the membrane, potas. chlor., and salicylic acid internally; steam and carbolic acid in the atmosphere of the apartment. But, alas! when I called Monday evening the membrane was visible in the fauces; and that trouble so very common in this class of cases, utter repugnance to swallow anything, was present. Immediately deciding that it was worse than useless to attempt to maintain her strength and combat the ravages of the disease by forcing down food and medicine, through the whole course of the attack, I turned my attention to the absorbing power of the rectum. I ordered the following injection to be given every six hours:

℞	Cinco-quin.	gr. iij.
	Potass. chloratis (sat. sol.)	ʒ ij.
	Acid. salicylic.	gr. iv.
	Tr. ferri chlor.	ʒ ss.
	Vini gallici	ʒ ij.
	Cream	ʒ ij.
	M.	

No medicine or food was attempted by the mouth, except keeping the tongue moist with cream, milk, ice, or ice-cream. The above injection was repeated every six hours till Tuesday evening, when, as her strength was rapidly failing, I increased the quantity of brandy to ʒ ss. in each injection, and ordered the enema repeated every four hours.

For five days and six nights, this little patient took every four hours, by enema, the following—

℞	Cinco. quin.	gr. iij.
	Pot. chlor. (sat. sol.)	ʒ ij.
	Acid. salicylic.	gr. iv.
	Tr. ferri chlor.	ʒ ss.
	Vini gallici	ʒ ss.
	Cream	ʒ ij.
	M.	

The only variations in the composition of the injections being, that after a day or so, an ounce of beef-tea was substituted for one of the cream; twice, the quantity of brandy was reduced one-half—but each time the failing pulse and weakness showed very plainly the need of more stimulus, and we were compelled to return to the usual quantity of half an ounce in each injection. During two or three nights, when the jactitation was extreme, it being difficult to keep her on the bed, ten drops of laudanum were added to each enema with the happiest effect. The same amount of laudanum was added whenever the bowels rejected an injection; for whenever this occurred, another was given immediately, and in no instance was the second rejected. Nothing surprised me more in the history of this case than the retentive and absorptive powers of the rectum. Twice only did we add the laudanum to prevent the rejection of the enema, and the quieting, tonic, and stimulating effects of an injection were plainly visible in less than an hour after its administration. The bowels moved quite regularly every other day, and although the movements generally occurred about two hours after an enema had been administered, nothing resembling an injection appeared in the fæces. On the contrary, the fæces were well formed and natural. After the first week, as the acute symptoms subsided, the injections were continued at intervals of six hours, the brandy at first being lessened one-half and soon discontinued: but the other constituents were continued in the same proportions for a fortnight longer, for it was not till then that the stomach would retain and digest food. As to the extent of surface invaded by the membrane, it completely covered the mouth, even to the lips, coating the fauces, and so blocking up the posterior nares that for four or five days the little sufferer was compelled to breathe wholly by the mouth. The stomach and small intestines were evidently partially or wholly coated, as she vomited patches of the membrane for a week after the subsidence of the acute symptoms, and patches were seen in the fæces for a fortnight more.

Fortunately the false membrane did not invade the air-passages. I think that in loading the air with steam and carbolic-acid vapor, and giving internally salicylic acid and chlorate of potash, we have the best remedies for limiting the extent of the membrane. The amount of medicine in each enema, especially of iron, may seem very large for a child so young; but after watching very closely the effect of each dose, I was assured not only that they did not harm the little one, but, on the other hand, that nothing less would keep her from sinking. Nothing but these heroic doses saved her from being destroyed by the poison of this, the most debilitating of diseases. As to these large doses of iron, I may say just here, that I have now under treatment a confirmed tubercular patient, who has a large cavity in his right lung—but who has gradually worked his way up from fifteen drops to fifty drops, three times a day, of muriated tincture of iron, and is steadily improving.

I have reported thus at length the treatment of this case of diphtheria, because it seemed very important to me, and I want my brethren in the profession to give this new method a trial. It may happen that in the next case the bowels will not act so kindly. This way of treating the disease has at least the merit of being painless. If there is any way of managing diphtheria and croup without caustics, which promises equally good results, let us hail it with joy. I have only the one case to report. I am glad I had no others of that disease to treat; mine is not the disposition to long for such cases, but I shall wait anxiously for reports from others as to the efficacy of this plan.

Progress of Medical Science.

Tænia and Raw Meat.—For some years past, the frequency of tænia, especially in children, has been assuming such unusual proportions in France, that it has attracted the especial attention of medical men. There was a rapid increase in the frequency of tænia in Paris during the year 1870, an increase due to the unaccustomed alimentation enforced by the siege of Paris. The frequency of tænia has not increased in that part of the army residing in France, as it has in the civil population; while among those stationed in Asia and Africa, particularly in Syria, Algeria, and Senegal, tænia is of frequent occurrence. The cause of this increasing appearance of the parasite in the civil population is to be found in the widely extended use of raw meat as a medicament, and of insufficiently cooked meat as food. The uniform alimentary régime of the soldiers explains the persisting rarity of tænia in the army in France, while in Algeria, etc., in consequence of the want of public hygiene, the bodies and débris of animals are often left exposed to the air, and the water used as drink becomes charged with eggs

or débris containing cysticerci. The prevalence of tænia in Abyssinia is due to the practice of eating the raw flesh of the sacrifices while it is still warm and palpitating. Formerly in St. Petersburg the Bothriocephalus alone was met with, but since the introduction of the use of raw meat in the treatment of the diarrhœa of children, cases of tænia in these children have been observed. Numerous isolated cases, moreover, have been reported, which show undoubtedly the dependence of tænia on the use of raw meat.

Tænia larvæ may also be ingested alive in underdone meat. M. Vallin has proved experimentally that the temperature of roast meat, as it is usually served, varies between 148° to 151° F., at the periphery, and 135° to 140° at the centre, and that the latter temperature is not sufficient to destroy the larvæ. He has proved that a temperature above 153° F. is necessary to destroy trichinæ.

Observation has also shown that it is the tænia mediocanellata which proceeds from the cysticercus of beef, while the armed T. solium is developed from the cysticercus of pork. The third variety of cestoid to which man is subject, the bothriocephalus latus, seems to be developed directly from the egg, and is propagated by the use of water vitiated by the excrement of men or animals.

The prophylaxis of tænia consists simply in subjecting beef and pork to a sufficiently high temperature in the process of cooking, or, as has been proposed by M. Roger, in the substitution of raw mutton for raw beef. The cœnurus, the only cestoid larva met with in sheep, is found exclusively in the brain, and accomplishes the second stage of its development in the intestine of the dog, but not of man. Finally, in each particular case, the advantages to be derived from the use of raw meat must be weighed against the inconsiderable dangers dependent on the development of tænia.—*Gazette Médicale de Paris*, March 11.

Palmar Bursal Tumors and the Bodies in Them.—In the course of a clinical lecture on this subject, M. Duplay referred to the difficulty of diagnosticating these tumors from the so-called crepitant lipomata, which are not so very rare. In the latter the fluctuation is obscure, and the sensation of crepitation not exactly the same as that furnished by the hordeiform cysts. These cysts are most frequently met with among mechanics, and are due to the constant pressure of the tools on the palmar tendons, the consequent irritation of their serous walls resulting in a subacute inflammatory affection. Under the influence of this irritation, a proliferation of the constituent elements of the serous walls takes place in spots, forming enlargements which project into the synovial cavity and raise the epithelium. Later they become pedunculated, and are finally separated. On the cadaver this process has been studied in its different periods of evolution, and the hordeiform bodies have been found to consist of exactly the same elements as the sub-serous bodies that preceded them. Their structure is very elementary; it consists of an amorphous or imperfectly fibrillated tissue, often softened, and containing sometimes granulations and the rudiments of a cellular formation. M. Duplay advises caution in making a prognosis, for these cysts sometimes suppurate and lead to phlegmonous inflammation, and sometimes excite a fungous synovitis, which is liable to extend to the neighboring articulations, and may then necessitate amputation. He advises abstention from all active treatment, where it is possible, for even if an operation prove successful, it leads to a complete adhesion of the serous surfaces, that interferes even more than the swelling with the movements of the fingers; while, on the other hand, the development of fungosities or of a diffuse phlegmon are to be feared. If an operation be imperative, however, the choice lies between puncture and incision, with or without injection of iodine. Subcutaneous incision is advisable on account of the difficulty of emptying the sac. If an incision be made at all, it should be free enough to evacuate the cyst readily, which may then be closed with gold-beaters' skin, compression applied, while absolute immobility of the limb is maintained.—*La Tribune Médicale*, March 19th, 1876.

Gastro-Enterotomy, with formation of an Artificial Anus in the small Intestine.—At a meeting of the Clinical Society of London, Mr. Maunder read a paper on this subject. The subject of the paper was a man sixty-eight years of age, who had been suffering a long time from constipation. Six weeks before his last attack he had passed blood per anum. The constipation was relieved at first by aperients, but subquently they had no effect. The abdomen was hard and tympanitic, and a globular swelling was felt a little below the umbilicus, toward the right side. Two days after the attack commenced, a large enema of five pints of warm water failed to give any relief, and it was inferred that the large intestine was empty, the conclusion being that the small intestine was obstructed near its entrance to the cæcum. Hiccough set in, and on the following day the small intestines were distended, their outlines being visible. These were then tapped with a small trocar and canula. Three days elapsed, and the symptoms were somewhat improved, though the vomiting was constant. Mr. Maunder then anæsthetized the patient, and did the following operation. An incision, about one and one-half inches long, was made extending between the umbilicus and the right anterior spine of ilium, the skin, fasciæ, muscles, and peritoneum being divided for half the length of the wound; the bowel was thus brought into view, though it did not protrude. It was then opened slightly, so as to permit the escape of gas; having been seized before it could disappear in the peritoneal cavity, and drawn forward into the wound, thus closing the abdominal opening. After opening the bowel, a fine fishing-gut suture and then silver-wire sutures were introduced, the latter to make six sutures. The bowel was then opened, so that the index finger might be introduced, when a large amount of gas and rusty, semi-solid faces escaped. Two weeks afterward, the patient was able to go about his room. Three months later, Mr. Brown, who was then attending him, stated that the patient was improved in health, and that he could walk a good distance every day. The patient gave himself an injection of warm water daily, through the opening, this being his only way to secure a movement. Mr. Maunder thinks there are several points essential to the success of this operation; viz., that the general contents of the abdomen should not be interfered with at all; the abdominal incisions should not be unnecessarily large, and the opening made in the bowel should be simply sufficient to prevent anything from entering or escaping from the peritoneal cavity, and this is accomplished by plugging the opening with the bowel. In the after-remarks, Mr. Thomas Smith related a similar operation which he had performed, in which he succeeded in opening the bowel, though too late to save the patient's life.—*The Lancet*, March 18, 1876.

The Pneumograph in Tetanus.—M. Richet thinks that the pneumograph will be of great use in determining the prognosis and proper treatment of tetanus. He

employed it recently in a case of this affection consecutive to gangrene of the feet following frost-bite. The disease proved fatal by asphyxia in sixteen hours. The respiratory tracings showed, at intervals, an interruption in expiration, a sort of expiratory spasm, due partly probably to spasm of the glottis, and partly to spasm of the abdominal expiratory muscles. In another case, the tetanic pause occurred during inspiration. In this case the symptoms lasted three days, and the patient died in a sort of comatose condition, but not asphyxiated. The tracings in this latter case were exactly similar to those obtained from a frog poisoned with strychnine, or excited by the induced current. Now, when the spasm is due to the inspiratory muscles, tracheotomy is useless, and a cure may be hoped for, because the hematosis will always be sufficient to permit the absorption of therapeutic agents, and give them time to subdue the medullary irritation. When, on the other hand, the spasm is expiratory, the hematosis, at a given moment, will be interrupted, and asphyxia be imminent. In such a case as this tracheotomy is indicated, and, in fact, this operation has succeeded in saving life in several cases of tetanus.—*Gazette Médicale de Paris*, April 1.

Dislocations of the Thigh, treated by Reid's Method.—Dr. R. O. Cowling reports six cases of dislocation of the thigh, treated by this method. Two of the patients were the oldest and youngest on record, the former being four months and the latter ninety years old. In the case of the child a thyroid dislocation was discovered, and the limb was restored to its shape and mobility by one revolution of the limb. The case ninety years of age had an iliac dislocation, which failed to be reduced after several revolutions of the limb had been made. The patient was suffering from several injuries, besides which fresh contusions appeared about the hips, the result of the manipulations; so, further attempts at reduction were not attempted. The patient died at the end of five weeks, and no post-mortem was obtained. Dr. C. thinks that Reid's method is as powerful a force as that of extension and counter-extension. In manipulating, fractures may occur from bringing down the limb too violently. He thinks that, to avoid any accident, it is best to be careful whenever the bone "hitches." As a preventive of abscesses after reduction, he advises the plastic apparatus, of plaster-of-Paris, starch, etc.—*The American Practitioner*, April, 1876.

The Anatomical Structure of the Soft and Hard Chancres.—Dr. J. Caspary, of Königsberg, expresses the opinion that the essential difference in the structure of the hard and soft chancres consists in a new formation of connective tissue in the former, while it never reaches the same development in the latter, because of the constant destruction of tissue which goes on. In recent indurations this new formation is seen in the dense, thick network which everywhere surrounds the cells, while in those of longer standing, bundles of fibres run between the newly formed cells. He regards the narrowing of the vessels which he observed in the older cases as the result and not the cause of the sclerosis. He believes that the formation of these fibres proceeds from the infiltration cells, and not from a growth inwards of the peripheral young connective tissue. This latter he believes to be in the nature of a capsule, due to inflammatory action.—*Vierteljahrsschr. f. Derm. u. Syph. III.*, 1, 1876.

Fractures of the Costal Cartilages.—Dr. E. N. Bennett gives some very interesting facts relative to this class of fractures. Under the microscope he has examined the cartilages, and thinks that a great deal may be learned in that way as to the predisposing causes of these fractures. He draws the following conclusions from his study of the subject. 1. That fractures of the costal cartilages may be arranged in three groups, the first containing recent fractures, which are consequences of grave injuries of the chest, and mere results of the fractures of the sternum or ribs; the second, united fractures caused by limited direct violence; the third, fractures the result of muscular action. 2. That degeneration of the cartilages, which precedes their ossification—the cleavage of the hyaline substance—may be regarded not only as a cause predisposing to fracture, but also as a cause determining its direction, which in the great majority of cases is transverse. 3. That oblique fractures are possible chiefly as secondary injuries. 4. That the callus in these fractures is developed as in bone, the broken cartilage participating in its development. 5. That the difference between the modes of union in bone and cartilage fractures consists, in the case of overlapping fractures, in the more limited development of callus in the cartilage fractures, and in all forms of fracture in the slowness with which the process of union would appear to be completed.—*The Dublin Journal of Science*, March, 1876.

Resection of Shaft of Tibia, leaving Periosteum. Reproduction of Bone.—Two operations of this description were performed by Prof. Spence at the Edinburgh Royal Infirmary. The first case was of a boy ten years old, who had acute necrosis of the shaft of the tibia. Prof. S. separated the periosteum all round the bone, with the periosteum scraper, and removed the entire shaft, after resection above and below. The wound was stuffed with lint soaked in carbolized oil. A posterior splint was applied and the limb slung. In two months new bone was thrown out from the periosteum, having the shape of the normal tibia. Four months after the operation, the patient was discharged, the bone being very strong, but the tibial ridge was deficient at the upper part, where the periosteum had ulcerated before the patient was admitted into the Infirmary. In the second case, that of a girl of eleven years, the whole shaft of the tibia was similarly affected and similarly removed, the resection above commencing immediately below the tubercle, while below it was an inch above the internal malleolus. Six months afterwards the entire shaft of the tibia had been reproduced, and felt perfectly solid. Prof. Spence thinks the advantages of this operation are: 1st, The early removal of a diseased texture, which affects the health; 2d, The removal of the diseased shaft lessens the risk of neighboring joints being affected; 3d, It obviates the risk of frequent hemorrhage from ulceration of enlarged periosteal vessels.—*The Lancet*, March 11, 1876.

Menstruation of Lapland Women.—Pastor Laestadius, of Jockmock, has undertaken to investigate this subject, with the object of showing how much reliance was to be put upon the statement that the Lapland women menstruate but once a year. He found, by making special inquires, that they first menstruated between sixteen and twenty years of age; that the intermediate period was four weeks, sometimes a little more or less; that the menstruation lasted four, and at most, six days. The Lapland women of whom the inquiry was made, claimed that this was the rule with them, as it is in other countries.

THE MEDICAL RECORD:

THE ARMY MEDICAL SERVICE.

At a time when the medical profession of this country is so much engaged in canvassing the merits of increased rank and pay in the medical department of the Army of the United States, the condition of the same staff in Great Britain becomes an object of interest. It is well known that the British medical department is in a bad way, and that its general availability as an effective arm of the Service has caused the deepest concern, not only among the medical profession, but with the legislators. The proposed short service scheme has proved itself so unpopular, that there is no reasonable hope for its becoming a law, while the discussion which it has initiated has alienated professional sympathy from the government more than would at first be imagined. The consequence has been, that there are still a number of vacancies to fill, and that candidates are not forthcoming.

The cause of this state of things is thus given in a recent number of the *Lancet*:—

"Taking the Services collectively, we may say that they have got a bad reputation with the profession; that this reputation was not the growth of yesterday, but has been slowly and steadily acquired; that there is a distrust of all government guarantees, and a belief that a position accorded to members of the profession in the public Services was, and still is, an unsatisfactory one; and that, as might naturally have been expected, a class of men have from time to time got into the Services which have, to some extent, justified the small estimation in which they appear to be held. Again, the public Services have to compete with civil life under certain obvious disadvantages—viz., those incidental to foreign service, and even expatriation, with probable risk to health, irksome or monotonous duties, distasteful discipline, and a well-grounded belief that the rewards do not follow professional or scientific attainments, but are attached to the exhibition of qualities that would have made a man successful if he had received relatively little education, but had been trained to habits of business. The truth is that students—at the English schools especially—and young medical men have of late years apparently ceased to regard the public services as a sphere of occupation and livelihood."

This seems to be the case in Great Britain; and, with slight modification, we have a parallel in the condition of the Services in our own country. There are vacancies in our medical staff which can be explained in the same way. As far as privileges with the attendant rank and pay are concerned, our English cousins have even better hope than we. For the past few years, every effort has been made to secure the passage of a law which should place the medical staff even on a decent footing with the other staff corps, but in vain; and even now, when so little is asked for, when the original demands for ordinary justice have dwindled into the insignificant petition for a slight increase in the number of officers who shall be privileged to hold the medium grades, Congress still hesitates to act, and the House Committee are timidly discussing the effect of the proposed innovation upon the Army appropriation. In regard to the whole matter, it must be acknowledged that not only the medical staff, but the profession generally, have placed themselves in the humiliating position of supplication rather than that of dictation. It is, however, beginning to wake up to the true state of the case, here as in England; and, while it may appear powerless to remedy existing evils, it may use the means of prevention for the future. In other words, if the government chooses to ignore the usual privileges to medical men, and refuses to grant reasonable requests, no competent and well-educated man will care to voluntarily place his neck into the yoke.

THE ABOLITION OF PRIZES BY MEDICAL PROFESSORS.

THE practice of conferring prizes upon students at Medical Colleges, for proficiency in special departments, has its advantages and its disadvantages. The latter so far predominate, that we are glad to learn that the College of Physicians and Surgeons of this city has abolished such awards altogether, and in their stead established some general prizes for proficiency in the final examinations for a degree. Although it might be made to appear that, in the offering of these prizes, the different members of the faculty stimulate extra study of their particular branches, yet this is almost always at the expense of time which should be devoted to a more general culture.

In the short period allowed for the mastery of even the principles of medicine, the student really has no time for becoming so proficient upon any one branch as shall entitle him to receive a medal. If students could combine all the mental qualifica-

tions necessary for being specialists in every branch, then the case might be different. As this is hardly possible, even among the most ambitious of aspirants for a degree, the main objection of sacrificing the whole course for the benefit of a part still holds good. The prizes for general proficiency would take into account all special talents and indirectly encourage their development in the prospect of adding to the chances at the final examination. The practice in the past, of giving prizes for services in special departments, is open to the serious objection of advertising the founders of said prizes to the general public on commencement days. On the whole, this is a very cheap and apparently innocent way of making known that Dr. A. is professor of surgery in the college, and Dr. B. of medicine, Dr. C. of obstetrics, and so on through the whole faculty. For fifty or one hundred dollars, each donor of such a prize has the privilege of this public announcement every year, with the chances of an advertisement in the next morning's daily paper. From a strictly business and personal point of view, it is certainly a profitable thing to be an awarder of a prize on such occasions; in fact, in the long run, it is even better to give than to receive. It is on this, as well as on some other accounts, that we commend the recent action of the faculty of the College of Physicians and Surgeons to the attention of similar educational bodies throughout the country.

Reports of Societies.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, April 12, 1876.

Dr. Charles K. Briddon, President, in the Chair.

(Concluded from page 307.)

MORBUS COXARIUS.

Dr. Briddon presented a specimen of the head of the femur, removed by operation from a patient having the following history: Mary Kelly, aged 14, native of Ireland, was admitted into the Presbyterian Hospital, January 18th, 1876. Previous history: In February, 1875, she began to suffer from pain in the right knee-joint; after a period of several weeks it extended to the hip, the leg became gradually flexed, and on the 3d day of March she entered Bellevue, where she received appropriate treatment for a period of four months. On leaving the hospital she got about on crutches, and in September a swelling presented itself in front of the hip-joint; this gradually increased in size, without any mitigation of her suffering.

Present condition: She is a poorly-nourished child; right leg is flexed on thigh, the latter on the pelvis; the limb is adducted and rotated inwards; a large abscess is situate in front of the great trochanter; she suffers pain on movements of the limb, and these are aggravated at night, and relieved by extension; the limb was gradually brought into a favorable position by weight and pulley, and January 24th the abscess was opened by Prof. A. C. Post; this procedure was followed by free discharge of pus.

February 1st (service of Dr. Briddon). Abscess is discharging freely; she is much emaciated; has well-marked hectic, and a decubitus; the limb is extended and maintained in that position by the usual apparatus; during the next six weeks other openings were made at fluctuating points, but these were all situated disadvantageously for drainage, and at no time could the presence of fluid be made out posterior to the trochanter; the bed-sore was her chief annoyance, and to this source of suffering particular attention was directed; the sinuses were irrigated daily with disinfectants, and she was placed upon a liberal supporting treatment; towards the middle of March the bed-sore was nearly healed; the sinuses discharged large quantities of ill-conditioned pus; hectic still continued; and it was deemed proper to institute an explorative operation, to insure a more favorable outlet for secretions, and at the same time afford an opportunity for investigation, that might suggest more prompt and decided measures.

The operation was made March 23d, 1875, in the presence of the Hospital Staff and several medical gentlemen. After the patient was placed under the influence of ether, it was ascertained that there was about an inch shortening, which was considerably diminished by extension; no crepitus could be elicited by various movements of the limb; a probe introduced through the various fistulous openings detected no carious bone; a transverse incision was made above the superior border of the great trochanter, united to a vertical one passing in the direction of its posterior border; this incision disclosed a cavity filled with concrete pus, and the eroded head of the femur more or less divested of capsule, which was in a condition of pulpy degeneration; the head was not displaced from the cavity of the acetabulum; a chain-saw was passed round, and a section was made through the softened structure of the neck and great trochanter, above level of trochanter minor; on removing the head from the acetabulum, that cavity was found extensively involved; the circular depression in the floor of the cavity was eaten through by caries, and a finger introduced through this aperture came in contact with an opposing finger introduced per rectum; the obturator, anal fascias, and their enclosed muscles intervening, the constituent bones entering into the composition of the acetabulum could be easily traced, from the fact that the Y-shaped piece had disappeared below the level of the contiguous bones; these were more or less eroded, but in some parts covered by granulations; such of the edges as appeared to be necrosed were removed, the cavity was filled with oakum, and the patient was placed upon Sayres' wire cuirass. The head of the femur was almost entirely divested of its cartilage of incrustation, more or less worm-eaten, or irregular on its surface, the neck on its outer and upper surface divested of periosteum, and what remained of capsule was in a condition of advanced disorganization.

24th. Patient has passed an uncomfortable night; unfortunately the cuirass only came from the instrument-maker's the night before the operation; and on applying it, it was found that a portion of it pressed on the nearly-healed bed-sore; this necessitated the introduction of compresses, to relieve pressure and consequent disturbance of the parts involved, which can only be prejudicial to the future progress of the case. For the first four days after the operation the temperature ranged between 98° and 101°, lower than it had been previous to that procedure; during the

same time the discharges from the wound were exceedingly fetid; subsequent to that less so, and of more purulent character. On the 27th diarrhœa set in, with gastric disturbance and occasional vomiting, and her pulse ran up to 140; temperature 102 8-10°. Fresh bed-sores formed at various points of contact; and although every conceivable device was used to relieve pressure, it was found almost impossible to accomplish the thing satisfactorily.

After this date the condition of the patient progressed from bad to worse, in spite of the most careful nursing; the diarrhœa persisted, and the discharges were occasionally colored with blood; the appetite failed, and nothing was taken but brandy and soda, or milk and lime-water, and she died on the first day of April.

DILATATION OF BLADDER FROM VALVE-LIKE PROSTATE, ETC.

Dr. Briddon presented the genito-urinary apparatus, removed from a patient, concerning which the following history was furnished:—

Presbyterian Hospital, (service Dr. Briddon.)—Thos. Clifford, aged 60, admitted Feb. 21st, 1876. *Previous history.*—Patient says he has always been a strong healthy man, gives an obscure history of a long continued urethral discharge; his employment of late years has exposed him to extremes of weather, and he has been accustomed to go with wet feet. For several years he has experienced some trouble in urinating, and has found it necessary to rise several times in the night to do so.

Present condition.—Is a man of large frame and moderately well nourished, his underclothes are wet with urine, and his external genitals are soddened with the same discharge; he has constant stillicidium, a large-sized catheter enters the bladder easily, and removes about eight ounces of residuum urine which is strongly ammoniacal.

Per rectum, moderate enlargement of the prostate is detected, but is not regarded as sufficient to cause such constant overflow.

Microscopically the urine was found to contain a large amount of pus and blood elements, and the filtered secretion contained a large amount of albumen. He was put upon the internal use of benzoic acid, and was directed to have his bladder injected twice a day with water acidulated with nitric acid. After this date, his condition varied, at times the urine was very bloody and fetid, and the condition of the bladder as a reservoir varied; the stillicidium was always present; but at times, the catheter found no residual urine, and the attending surgeon expressed the opinion that he regarded the constant dribbling without distention, as signifying that the prostatic urethra was opened out by an enlarged wedge-shaped middle lobe. His general condition became gradually worse; failing gradually, he died on the 6th April.

Post-mortem examination.—Dr. T. E. Satterthwaite, Pathologist to the Hospital, April 7, 1876. Body well nourished; nothing abnormal noticed on the surface. *Thoracic cavity*, no abnormal amount of fluid in pericardial sac. Heart enlarged in transverse diameter, left ventricle considerably thickened, no dilatation of auricles or ventricles, valves normal, aorta faintly atheromatous, but not stiff. *Lungs:* no abnormal amount of fluid in pleural cavities, lungs normal, posteriorly hypostatic congestion. *Liver*, somewhat fatty. *Spleen*, small and contracted. *Kidneys:* in an advanced stage of diffuse chronic nephritis; capsules slightly adherent, surface of cortex granular showing cysts; ureters dilated. *Bladder* dilated—trabeculated, middle lobe of prostate as large as pullet's egg, and round, forming a sessile non-pedunculated tumor; false passage in the membranous portion, about seven and a half inches from the meatus. Head and intestines not examined.

A third specimen by Dr. Briddon was one of

SUBMUCOUS UTERINE FIBROMA AND LIPOMA OF THE NECK.

Margaret Pell entered the Presbyterian Hospital (service Dr. Briddon), March 13th, 1875. She is a widow, her youngest child being ten years old, has suffered from tænia for some time past; has a fatty tumor six inches in its long diameter, situated over the left sterno-mastoid overlapping its anterior border, and encroaching upon the lower portion of the tracheal region just above the supra sternal notch.

Per vaginam, a tumor of firm consistence about the size of a billiard-ball, continuous above through the medium of a pedicle about the dimensions of the index-finger, with the inner surface of the posterior wall of the cervix. Examined by the sound, the uterus is discovered to be of normal size. She has never suffered from uterine colics, and has only been troubled with menorrhagia for the last six months.

March 16.—The vaginal growth, steadied by a fillet of tape, was removed by the wire écraseur, the wire being passed high up within the cervix. After removal the parts were exposed by Sims' speculum, and it was ascertained that it was severed close to the cervical wall. The lipoma was removed by single long incision.

THE STRUCTURE OF CARTILAGE.
